Heating Arrangements. The Need for Better Heating in Forging and Forming Practice. Forging & Heat Treating, vol. 8, no. 4, Apr. 1922, pp. 202–204, 2 figs. Typical arrangements of chambers and working openings in forging and heating furnaces to meet nature of process and material to be heated.

FURNACES, METALLURGICAL

Design. Possibilities of Improvements in the Design and Operation of Metallurgical Furnaces (Entwicklungsmöglichkeiten bei hüttentechnischen Oefen), Georg Bulle und H. Rosin. Stahl u. Eisen, vol. 42, no. 14, Apr. 6, 1922, pp. 529–532, 3 figs. Author demonstrates importance of taking radiation losses into consideration and points out that great saving in fuel can be effected through proper shape and size of furnace and adequate insulation. Practical examples.

Gas Firing. Modern Gas Firing (Neuzeitliche Gasfeuerungen), M. Schimpf. Glückauf, vol. 58, no. 15, Apr. 15, 1922, pp. 429–433, 5 figs. Discusses question of using surplus gas in mining districts, and describes experiments with Eickworth and Rodberg burners for burning furnace and excess gas.

Oil-Fired. Oil Firing of Open-hearth Furnaces in Steel Foundries (Le Chauffage à l'Huile des Fours Martin), P. Jolly. Fonderie Moderne, no. 3, Mar. 1922, pp. 78–79. Discusses advantages of oil, such as absence of sulphur, regulation of temperature, intermittent operation, etc.

Temperature Calculation. Calculation of Working Temperatures in Metallurgical Furnaces (Errechnung der Arbeitstemperaturen in metallurgischen Oefen), Hugo Bansen. Stahl u. Eisen, vol. 42; nos. 7, 8, 10 and 11, Feb. 16, 23, Mar. 9 and 16, 1922, pp. 245–253, 291–297, 370–375 and 423–426, 17 figs. Notes on drop in temperature as calculated and actually reached; pyrometric evaluation of fuels; dynamic conditions for flame formation; required workpiece temperatures; temperature pressure between workpiece and flame; heat transmission. Determination of most suitable fuel.

FURNACES, OPEN-HEARTH

Regenerative. Control of Heat Economy in Regenerative Furnaces (Ueberwachung der Wärmewirtschaft bei Regenerativefeuerungen), H. Berger. Wärme (Zeit. für Dampfkessel u. Maschinenbetrieb), vol. 45, no. 1, Jan. 6, 1922, pp. 12–14. Includes heat balance of regenerative furnace and auxiliary

generator. Notes are given both on sources and prevention of losses.

G

GAS

B.t.u. Calculation. New Graphic B.t.u. Calculator, Minor C. K. Jones. Gas Age-Rec., vol. 49, no. 13, Apr. 1, 1922, pp. 393–394, 1 fig. Discusses use of chart for calculation of heating value in B.t.u. per cubic foot of a gas, by which lengthy and laborious calculations are avoided.

Fuel, Future Use. Gas—the Fuel of the Future, Thomson King. Am. Gas Jl., vol. 116, no. 14, Apr. 8, 1922, pp. 321–322 and 332–333. Deals with near future which can be plainly discerned, and more distant future which must be dealt with in more general terms.

Proper Utilization. Proper Utilization of Gas Important, Andrew M. Rowley. Oil & Gas Jl., vol. 20, no. 48, Apr. 27, 1922, p. 12, 1 fig. Domestic consumers waste 150 billion ft. annually, hastening depletion of supply and bringing closer day of costly substitutes.

Relative Usefulness of. Relative Usefulness of Gases, Floyd W. Parsons. Gas Age-Rec., vol. 49, no. 16, Apr. 22, 1922, pp. 483–484, 506. Results of investigation of different gases by U. S. Bur. of Standards. Proper burning conditions of air to gas and most economic heating value standards for gas.

GAS PRODUCERS

Glass Works. Gas-Producer Operation in Glass Works (Der Betrieb der Gaserzeuger in den Glashütten), Hubert Hermanns. Wärme (Zeit. für Dampfkessel u. Maschinenbetrieb), vol. 45, no. 1, Jan. 6, 1922, pp. 14–17, 5 figs. Presents heat balance of a glass furnace and discusses losses in Siemens producers.

Outside. Outside Producers at Racine, H. R. Broker. Am. Gas Jl., vol. 116, no. 14, Apr. 8, 1922, pp. 325–329, 4 figs. Notes on installation of producer plant consisting of two high-pressure producers which can gasify at least one-half braize and one-half small or nut coke, and each of which is rated to gasify 25 tons of fuel per day. Saving effected in labor and fuel.

Reinforced-Concrete. Reinforced-Concrete Gas Producer. Engineer, vol. 133, no. 3457, Mar. 31, 1922, p. 364, 2 figs. Experimental producer built in Italy in accordance with patents of O. R. Verity. It is claimed that reinforced-concrete construction allows of economy in first cost of over 50 per cent, as compared with metal construction, and there is also economy in maintenance.

Transforming Solid Fuel into Gas. Gas Generator, Fusing Ash Type (Le gazogène à fusion des cendres), A. Fichet. Mémoires et Comptes Rendus des Travaux de le Société des Ingenieurs Civils de France, vol. 74, no. 10–12, Oct.-Dec. 1921, pp. 593–638, 8 figs. Development of Ebelmen gas producer for transforming solid fuel into gas and using this in metallurgical furnaces.

Types. Gas Producers (Les Gazogènes), Louis Garand. Chaleur et Industrie, vol. 3, no. 24, Apr. 1922, pp. 1157–1192, 3 figs. Reviews development and describes most recent types made in France.

GAS TURBINES

Thyssen-Holzwarth Oil and. Thyssen-Holzwarth Oil and Gas Turbines, W. Schüle. Motorship, vol. 7, no. 5, May 1922, pp. 351–355, 9 figs. Describes unique internal-combustion engine invented by Hans Holzwarth, and gives results of tests. (Extract.) Translated from German.

GASES

Combustion of Mixtures. The Combustion of Complex Gaseous Mixtures. William Payman and Richard Vernon Wheeler. Chem. Soc. Jl., vol. 121–122, no. 713, Mar. 1922, pp. 363–379. Concludes that during propagation of flame in mixture of several inflammable gases with air at given speed, gas which will monopolize most oxygen is that which when burning alone with same speed of flame is associated with most air.

GASOLINE

Substitutes. Gasoline Substitutes and Synthetic Products, Ernest Owen. Oil Trade Jl., vol. 13, no. 4, Apr. 1922, pp. 13–14 and 92. Development of cracking processes, methods designed to conserve fuel; using catalysts; oil-shale projects, and principal shale sources; alcohol a promising source.

GEAR CUTTING

Commercial Practice. Commercial Gear-cutting Practice. Machy. (Lond.), vol. 20, no. 498, Apr. 13, 1922, pp. 23–36, 20 figs. Spur gear-cutting machines of rotary-cutter type.

Commercial Gear-Cutting Practice. Machy. (Lond.), vol. 20, no. 500, Apr. 27, 1922, pp. 109–112, 6 figs. Describes automatic spur gear cutter by John Holroyd & Co., Ltd.

Multiple Shapers. Stevenson Multiple Gear Shaper. Machy. (Lond.), vol. 19, no. 496, Mar. 30, 1922, pp. 791–793, 5 figs. Describe new 6-A downstroke model.

GEAR DRIVE

Nodal Arrangements of. Nodal Arrangements of Geared Drives, J. H. Smith. Shipbldg. and Shipg. Rec., vol. 19, no. 15, Apr. 13, 1922, pp. 455–456. Illustration of violent effects of faulty arrangement on teeth of gear wheels.

GEARS

Hydraulic-Power Transmission. Hydraulic Power Transmission Gears, M. H. Sabine. Practical Engr., vol. 65, nos. 1828, 1831, 1832 and 1833, Mar. 9, 30, Apr. 6 and 13, 1922, pp. 151–154, 205–206, 221–222 and 235–236, 8 figs. Mar. 9: Discusses variable power transmission by oil in which a prime mover revolving in one direction at constant speed is coupled direct to a variable-delivery pump which delivers oil to a fluid motor, usually of fixed capacity. Mar. 30: Working of gear and features of Carey pump. Apr. 6 and 13: Carey pump cylinder action, pulsations and vibration; success of Hele-Shaw gear.

Involute. The Involute Gear Tooth XII, A. Fisher. Machy. (Lond.), vol. 20, no. 498, Apr. 13, 1922, pp. 55–58, 8 figs. Generation by pinions.

Latest Practice. Gear Makers' Convention of Much Technical Interest, P. M. Heldt. Automotive Industries, vol. 46, no. 17, Apr. 27, 1922, pp. 901–906, 5 figs. Papers presented on good hob practice, use of projection comparator in testing gear teeth, proportion of industrial gears, the grinding of gear teeth and new system of bevel gears.

One-Tooth Pinion. A Novel One-Tooth Pinion. Eng. Production, vol. 4, no. 82, Apr. 27, 1922, p. 396, 4 figs. Details of an interesting high-ratio gear.

Teeth Repairing. Repairing Broken Gear Wheel Teeth, G. H. Radebaugh. Brick & Clay Rec., vol. 60, no. 8, Apr. 18, 1922, pp. 617–620, 14 figs. Various styles of gears, four methods of repairing cast teeth, description of stud method which does not require commercial repair shop.

Worm-Reduction. Worm Reduction and Change-speed Gearing. Engineer, vol. 133, no. 3457, Mar. 31, 1922, pp. 352–354, 4 figs. Describes new invention the novelty of which consists of entire absence of usual spur wheels and use instead of worms and worm wheels.

GRINDING

Auger Bits. Auger Bit Grinding Operations, K. H. Lansing. Abrasive Industry, vol. 3, no. 5, May 1922, pp. 154–156, 7 figs. Wood boring augers and bits are finished almost entirely by manual operations involving solid and setup wheels.

GRINDING MACHINES

Planetary Spindle, with. Grinding Machine with Planetary Spindle, W. Pockrandt. Eng. Progress, vol. 3, no. 4, Apr. 1922, pp. 88–91, 10 figs. How planetary spindle works. Grinding machines with vertical and horizontal grinding spindle. Comparisons between the two types of grinding machines.

GUN MOUNTS

Christie Motor Carriages. Christie Motor Carriages, H. E. Pengilly. Army Ordnance, vol. 2, no. 11, Mar.-Apr. 1922, pp. 285–290, 6 figs. Describes new tractor type of carriage developed to meet need for mobile artillery capable of high speed on good roads of present Army Transport, and of negotiating most difficult terrain encountered in field maneuvers.

H

HANDLING MATERIALS

Car Tipping in Factory Yards. Modern Appliances for Tipping Wagons in Factory Yards, E. Krahnen. Eng. Progress, vol. 3, no. 5, May 1922, pp. 111–113, 6 figs. Electrically operated tippers with toothed segments or traction ropes; double-end tippers; swinging tippers.

Electrical Plants. Modern Electrical Handling Plant, H. H. Broughton. Beama, vol. 10, nos. 3 and 4, Mar. and Apr. 1922, pp. 210–216, 8 figs., pp. 325–332, 3 figs. Mar.: Gives examples of various types of cranes and bridge transporters and discusses grain handling. Apr.: Canadian and South African grain-handling installations. Data on use of grabs to increase unloading of ore into Great Britain. Buying cargo cranes.

Internal, Textile Finishing Plant. Internal Transportation in a Large Textile Finishing Plant, A. Hamilton Church. Management Eng., vol. 2, nos. 4 and 5, Apr. and May 1922, pp. 197–202 and 293–296, 14 figs. Describes transportation methods of plant of The Mount Hope Finishing Co., Taunton, Mass.

Methods. Handling Material in the Steinway Factories, Paul Bulhuber. Management Eng., vol. 2, no. 5, May 1922, pp. 263–268, 10 figs. Methods used for raw materials parts, and finished products.

HEAT

Economical Use. Economical Use of Heat (Sparsame Temperaturwirtschaft), K. Schreber. Dinglers Polytechnisches Journal, vol. 337, nos. 6 and 7, Mar. 25 and Apr. 8, 1922, pp. 51–54 and 61–65, 4 figs. Discusses relation of value of unit of work and value of unit of heat, and gives various illustrations of boilers.

Conservation. Control of Heat Consumption (Ergebnisse der wärmetechnischen Betriebsüberwachung), H. Berner. Wärme (Zeit. für Dampfkessel u. Maschinenbetriebe), vol. 45, nos. 1 and 2, Jan. 6 and 13, 1922, pp. 6–9 and 30. Fundamentals of control; operating tests; measuring devices; loss and utilization of waste heat; the heat pump; waste energy; furnace and other losses; savings effected through control.

HEAT TRANSMISSION

Building Materials. Temperature Study in a Wall of Undefined Thickness Whose Faces are Subject to a Uniform Periodical Variation of Temperature (Étude du Régime des températures dans l'épaisseur d'un mur indefini dont les duex faces sont soumises à une même variation périodique de la température), (J. Seigle. Révue de l'Industrie Minerale, no. 30, Mar. 15, 1922, pp. 135–145, 11 figs. Mathematical paper on heat transmission and heat conductivity of materials such as brick.

HEAT TREATING

Gas Firing. Gas Wins Out for Heat Treating, J. P. Lafore. Gas Age-Rec., vol. 49, no. 15, Apr. 15, 1922, pp. 451–452 and 456, 3 figs. Describes gas equipment of eastern metallurgical plant which was installed after considerable experience with coal, electricity, oil and gas.

Mediums. Fuels, Burners, and Quenching Mediums for Heat treatment, S. P. Rockwell. Machy. (Lond.), vol. 20, no. 500, Apr. 27, 1922, pp. 100–103, 3 figs. Advantages and disadvantages of different kinds of fuel, types of burners, and description of results obtained by various quenching baths.

HEATING

Flue-Gas Utilization for. The Heating of Factory Rooms and Halls through Utilization of Flue Gas (Neuzeitliche Grossraumheizung mittels Rauchgasausnutzung), Otto Brandt. Wärme (Zeit. für Dampfkessel u. Maschinenbetrieb), vol. 45, no. 1, Jan. 6, 1922, pp. 4–6, 6 figs. Describes two systems and points out their advantages and economy.

HEATING, ELECTRIC

Losses. The Determination of Heat Loss, Walter W. Nobbs. Beama, vol. 10, no. 4, Apr. 1922, pp. 312–320, 2 figs. Fallacies in past heating determination in the formulas in coefficients and tables. Heating computations.

Residences, Tacoma, Wash. Electric Heating of Residences in Tacoma. Heat. & Vent. Mag., vol. 19, no. 4, Apr. 1922, pp. 41–45, 6 figs. Interesting features of installations in 795 residences, 54 apartments and 76 business and other buildings.

HEATING, HOT-AIR

Fan Furnace System. Fan Furnace Heating of a Theatre. Sheet Metal Worker, vol. 13, no. 6, Apr. 14, 1922, pp. 171–173, 5 figs. Describes heating and ventilating system of Rialto Moving Picture Theatre, Hamilton, Ohio, in which vertical sectional furnaces are used as air heaters, and fan is used to insure positive distribution and proper ventilation.

Leader Sizes, Figuring. Simplified Scientific Method of Figuring Leader Sizes, P. J. Dougherty. Sheet Metal Worker, vol. 13, no. 7, Apr. 28, 1922, pp. 209, 215. Two rules by which to determine heat losses from building as well as leader pipe sizes.

HEATING, STEAM

Central Stations. The Neukoelln Municipal Central Station for Distance Heating. Eng. Progress, vol. 3, no. 4, Apr. 1922, pp. 77–78, 2 figs. At present 14 individual buildings or groups of buildings in a Berlin suburb are supplied with heat from this common source. Heating plant was designed and executed by Körting Bros., Berlin Branch. Required heat supply amounts to 5,800,000 kg-cal. per hr., and it is intended to enlarge station to max. heat output of 15,000,000 kg-cal. per hr.

Report on Experiments With a Coke Economizer of the Zuppinger Type by the Thermotechnical Division of the Union of Central Heating Stations (Bericht über die Versuche der wärmetechnischen Abteilung im Verband der Centralheizungs-Industrie mit dem Kokssparer Bauart "Zuppinger"), A. Grossmann. Gesundheits-Ingenieur, vol. 45, no. 15, Apr. 15, 1922, pp. 193–201, 5 figs. Gives results of a number of evaporation tests confirming advantages of Zuppinger apparatus.

HELICOPTERS

Propeller Screws. Helicopters (Les hélicoptères), W. Margoulis. Aeronautique, vol. 4, no. 34, Mar. 1922, 16 pp. (supplement), 10 figs. Results of experiments carried out to determine mechanical functioning of propeller screws.

HIGHWAYS

Transportation Economics. Traffic Facts Shown by Highway Transportation Surveys. Automotive Industries, vol. 46, no. 17, Apr. 27, 1922, pp. 917–919, 1 fig. Overloading is prevalent in hauling all commodities. Trucks handle large percentage of manufactured products carried over route covered by surveys; 3.2 passengers per car is average determined; 2-ton trucks form 16 per cent of total. Census example of needed transport studies.

HOISTS

Portable Column. The Modern Column Hoist, F. A. McLean. Can. Min. Jl., vol. 43, nos. 11 and 12, Mar. 17 and 24, 1922, pp. 152–156 and 169–172, 15 figs. Mar. 17: Describes modern portable column hoist, its construction and use in mine and quarry operation. Mar. 24: Tugger slushing in metal and coal mines.

HOUSING

Location of Blocks of Dwellings. Location of Blocks of Dwellings by the Compass and Available Sunshine (Die Lagerung städtischer Wohnblocks zur Himmelsrichtung mit Rücksicht auf die Besonnungsverhältnisse), K. A. Hoepfner. Gesundheits-Ingenieur, vol. 45, nos. 12 and 14, Mar. 25 and Apr. 8, 1922, pp. 148–150 and 181–185, 14 figs. Shows by diagrams and curves amount of sunshine available during year for houses running east-west, north-south, northeast-southwest, etc.

HYDRAULIC MACHINERY

Engines. A New Hydraulic Engine (Eineneue

Wasserkraftmaschine "Aquapulsor"), R Winkel-Glasers Annalen, vol. 90, no. 6, Mar. 15, 1922, pp. 92 97, 21 figs. Describes new type known as aquapulsor, and its use for irrigation and drainage, and for filling and emptying of navigation locks.

HYDRAULIC TURBINES

Large Installations. Some Large Turbine Installations in Austria and Other Countries (Einige grössere Turbinenanlagen in Oesterreich und im Ausland), W. Hahn. Elektrotechnik u. Maschinenbau, vol. 40, nos 12 and 13, Mar. 19 and 26, 1922, pp. 133–139 and 147–149, 12 figs. History of development and examples of large turbine installations in America, Scandinavia, Japan, Germany, etc.

Molding 50-Ton Runner. Molding a 50-Ton Turbine Runner. Foundry, vol. 50, no. 8, Apr. 15, 1922, pp. 318 321, 6 figs. Set of cores forming mold was assembled on an iron plate divided in two for convenience in setting last of vane cores.

HYDRODYNAMICS

Equations. Ambiguous Solutions of the Hydrodynamic Equations (Ueber mehrdeutige Lösungen der hydrodynamischen Gleichungen), George Jaffé. Physikalische Zeit., vol. 23, no. 6, Mar. 15, 1922, pp. 129–133, 4 figs. Presents example, similar to Villat example, of two-directional flow against a hollow space, thus forming a dead-water area of indeterminate size in the space.

HYDROELECTRIC DEVELOPMENTS

Belgium. Utilization of Belgian Hydroelectric Resources (Avant-Projet de captation des energies hydrauliques Belges), Herman Chauvin. Révue Universelle des Mines, vol. 11, nos. 1, 3, 4, 5, 6, Oct. 1, Nov. 1, 15, Dec. 1, 15, 1921, pp. 1–28, 261–277, 509–523, 629–644, 15 figs. on supp. plates. Oct. 1: Discusses general questions of river water supply and control for power purposes; and barrage work carried out in various rivers. Nov. 1: 15, Dec. 1 and 15: Describe work carried out on the Sambre and Meuse rivers.

Chippawa-Queenston. First 50,000 hp. Unit of Chippawa-Queenston Power Scheme. Elec. News, vol. 31, nos. 4, 5, 6, 7 and 9, Feb. 15, Mar. 1, 15, Apr. 1 and May 1, 1922, pp. 29–34, 28–33, 30–34, 27–34 and 32–35, 35 figs. Feb. 15: Series of articles describing work in connection with location of intake, canal and power house; also general design. Mar. 1: Details of hydraulic installation. Mar. 15: Excavation methods for moving 17,000,000 cubic yards of material and cutting through rock and earth; lining of canal; etc. Apr. 1: Design of power plant and specifications and installation of major apparatus May 1: Description of generators nos. 4 and 5 being completed by Can. Gen. Elec. Co.

Switzerland. The Silser Lake-Bergeller Power Plant Project (Die projektierten Silsersee-Bergeller Kraftwerke), Adolf Salis. Schweizerische Bauzeitung, vol. 79, no. 13, Apr. 1, 1922, pp. 161–164, 8 figs. Discusses present project for utilization of water power of Silser Lake in the Upper Engadine, Switzerland.

HYDROELECTRIC PLANTS

Germany. Supplying the Town of Passau with Electric Power and the Power Station Hals on the Ilz (Die Versorgung der Stadt Passau mit elektrischer Energie und das Kraftwerk Hals an der Ilz), Albert Sturm. Bauingenieur, vol. 3, no. 6, Mar. 31, 1922, pp. 170–173, 7 figs. Describes work of damming the Ilz and construction of buildings for machines; etc.

Italy. Thermoelectric Plant at Torre del Lago (Impianto termoelettrico di Torre del Lago Trazione elettrica). Revista Tecnica delle Ferrovie Italiane, vol. 21, no. 2, Feb. 15, 1922, pp. 33–42, 19 figs. Describes Italian thermoelectric plant worked under a concession supplying power to state railways, state participating in profits when over 7 per cent dividends are paid.

Norway. The Aust-Agder Power Station (Aust-Agder Kraftverk), Kr. T. Westbye. Elektrotecknisk Tidsskrift, vol. 35, no. 10, Apr. 5, 1922, pp. 73–76, 12 figs. Describes construction work and equipment, transmission lines, transformer stations, etc.

Switzerland. The Olten-Geosgen Hydroelectric Power Station (Centrale hydroélectrique suisse d' Olten-Goesgen), H. De Watteville. Houille Blanche, vol. 21, no. 174, Jan.-Feb. 1922, pp. 1–5, 5 figs. Describes construction work, including damming of the Aar; and equipment, including Brown-Boveri 7050 k.v.a. alternators at 7700–8400 volts, transformers, long-distance transmission at 70,000 volts.

I

ICE MANUFACTURE

Raw-Water Can System. Modern Systems for Manufacture of Raw Water Can Ice, Van Rensselaer H. Greene. Ice and Refrigeration, vol. 62, no. 4, Apr. 1922, pp. 287 288. Some details of method of obtaining clear ice by means of blowing air through it while freezing.

Sea Water. Using Sea Water in Ice Manufacture. Ice and Refrigeration, vol. 62, no. 4, Apr. 1922, p. 320. Experiments by Dyle and Bacalan demonstrating advantages of sea-water ice for some types of refrigeration.

ICE PLANTS

Electrically Operated. The Electrically Operated Ice Plant, H. J. Macintire. Ice and Refrigeration, vol. 62, no. 4, Apr. 1922, pp. 273 277. Some results of advance in use of electricity in last five years.

Japanese. A Japanese Ice Plant, L. H. Jenks, Jr. Refrig. World, vol. 57, no. 4, Apr. 1922, pp. 14–16, 8 figs. Recently completed installation on Island of Hikoshima for Imperial Ice Co.

INDICATORS

Optical. Optical Indicator. Eng. Progress, vol. 3, no. 5, May 1922, p. 114, 5 figs. Description of manograph indicator made by O. S. A. Apparatus Co. Ltd., based upon deflection of beam of light striking mirror by which it is reflected.

Planimetric. Planimetric Indicator (Planiketrierender Indikator), L. Gumbel. Zeit. des Vereines deutscher Ingenieure, vol. 66, no. 13, Apr. 1, 1922, pp. 298–299, 6 figs. Describes indicator developed by author, consisting of an indicator cylinder of usual dimensions with outside spring and without writing device. The gear is so arranged that the indicator records progressively.

INDUSTRIAL MANAGEMENT

Antagonism. The Inevitable Antagonism Between Employers and Employees. Management Eng., vol. 2, nos. 4 and 5, Apr. and May 1922, pp. 246–247, 308–309. Discussion by various authors of article by C. E. Knoeppel in March issue.

Charting, Authority and Responsibility. Charting Authority and Responsibility to Show Complex Management Relationships. Boyd Fisher. Management Eng., vol. 2, no. 5, May 1922, pp. 281–284, 2 figs. Lack of value of familiar organization charts and suggestions for an samples of worthwhile ones.

Cost-Control Committee. The Organization and Operation of the Cost Control Committee Plan, John H. Van Deventer. Indus. Management, vol. 63, no. 5, May 1922, pp. 267–272. Machinery of plant for building economic morale to reëstablish profit margins.

Cost Predetermination. The Determination of Costs, J. McD. Cronin. Indus. Management, vol. 63, no. 4, Apr. 1922, pp. 221–224. A system which will reveal true costs in time to control them.

Earnings, Interpreting Average. Interpreting Average Hourly Earnings on Semiautomatic Operations, Paul Faltin and Leon Blog. Management Eng., vol. 2, no. 4, Apr. 1922, pp. 215–219, 1 fig. Adoption of piecework system of wage payment.

Executive Ability. Measuring Executive Ability, William E. Dunn. Indus. Management, vol. 63, no. 5, May 1922, pp. 292–295. Suggesting measure of value and deducing factors that compose it.

Foremen, Training. Foremen Training as a Factor in Cost Reduction, B. M. Nussbaum. Indus. Management, vol. 63, nos. 4 and 5, Apr. 1922, pp. 229–233, 297–302. Apr.: Analysis of lecture-class method, conference-discussion method and standard-group study course, and advantages and disadvantages of each. May: Means of getting and holding the foremen's interest.

Foundry Costs. Volumetric Efficiency as a Measure of Foundry Costs, Douglas T. Sterling. Indus. Management, vol. 63, no. 4, Apr. 1922, pp. 201–205, 3 figs. Relations between floor space, flask volume and weight of castings.

Happiness, Importance of. Making Happiness a By-Product of Industry, Geo. W. Hanley. Indus-Management, vol. 63, no. 5, May 1922, pp. 287–291, 8 figs. Restoring to business human interest and coöperation betwen employer and employee.

Incentives and Rate Setting. Incentives and Rate-Setting Applied to the Smaller Plant and Varied Product, E. Wadsworth Stone. Management Eng., vol. 2, no. 4, Apr. 1922, pp. 205–208. Value of practical encouragement applied to smaller plant.

Production Cost Cutting. Cutting Production Costs by Combining Manufacturing Operations, C. B. Bartlett. Indus. Management, vol. 63, no. 4, Apr. 1922, pp. 198 200, 2 figs. Operations which can be combined substantially decreasing costs as well as reducing hazards.

Profits, Reëstablishing for Small Factory. Re-Establishing the Profits of the Small Factory, Ernest Cordeal. Indus. Management, vol. 63, no 4, Apr. 1922, pp. 251–254. Importance of vesting authority to hire and discharge employees in special department.

Scope. Looking Management Engineering in the Eye, Erwin H. Schell. Management Eng., vol. 2, no. 4, Apr. 1922, pp. 233–236. High standards, assimilating new ideas, an art as well as science; present day demands.

University Training in Factory. Taking University Training to the Factory, Paul M. Atkins. Indus. Management, vol. 63, no. 4, Apr. 1922, pp. 239 242, 1 fig. Plan to increase receptivity of working force to new ideas, train employees for advancement and discover those best fitted for promotion.

Wastes. Searching Out the Invisible Wastes, C. J. Morrison. Indus. Management, vol. 63, no. 4, Apr. 1922, pp. 196–197. Some prominent points of attack for cost cutting campaign.

[See also EXECUTIVES; SAFETY ENGINEERING; TIME STUDY; WASTE.]

INDUSTRIAL TRUCKS

Electric. Electric Vehicles. Gen Elec. Rev., vol. 25, no. 4, Apr. 1922, pp. 200–259, 62 figs. Special issue containing articles by various authors on the battery vehicle in England; electric trucks in express service and in automotive field; electric passenger vehicle; operation; design and application of motors; controllers and resistances for storage-battery-driven vehicles; charging systems; advantages of gasoline and electric trucks with interchangeable parts; etc.

INSPECTION

Methods. Inspection Methods that have Proved Successful, H. Alton. Can. Machy., vol. 27, no. 17, Apr. 27, 1922, pp. 17–19 and 21. See that specifications are correct. Incoming material should be carefully inspected before going into stores. Where gaging is most effective. Coöperation of departments.

INSTRUMENTS

Precision. Practical Application of Precision Instruments, H. Alton. Can. Machy., vol. 27, no. 16, Apr. 20, 1922, pp. 24–26, 6 figs. Construction of different gages; improved design increases efficiency; reducing weight of larger sizes; combining blocks for checking dimensions; testing micrometers for wear.

INSULATION, HEAT

Thermoconductivity of. Heat Insulators. Refrig. World, vol. 57, no. 4, Apr. 1922, pp. 21–22. Abstract of special report of Food Investigation Board of G. B. on thermal conductivity of insulating materials usually employed.

INTERCHANGEABLE MANUFACTURE

Tolerance System. Tolerance System in Interchangeable Manufacture, C. W. Ham. Sibley Jl. of Eng., vol. 36, no. 4, Apr. 1922, pp. 66–67, 74. Definitions of terms; examples of their use; undesirability of specifying closer tolerances than necessary.

INTERNAL-COMBUSTION ENGINES

Alcohol for Fuel. Alcohol for Motor Fuel. Soc. Automotive Engrs. Jl., vol. 10, no. 5, May 1922, pp. 364–365. Possibilities of more general use and points in favor of and against it.

Castings. Castings for Internal Combustion Engines, Ben Shaw and James Edgar. Foundry Trade Jl., vol. 25, no. 293, Mar. 30, 1922, pp. 236–239, 14 figs. Discusses production of pistons, their heat treatment and molding details. Also discusses castings for crank-case bottom, water inlet, front cover, and gear boxes.

Combustion Process. Combustion Process in Explosion Engines (Forbraendingsprosesser i eksplosjonsmotorer), W. Holwech. Teknisk Ukeblad, vol. 69, nos. 9, 10 and 12, Mar. 3, 10 and 24, 1922, pp. 78–80, 87–91 and 116–118, 12 figs. Mar. 3: Mixing of gases; compression; ignition; combustion; expansion. Mar. 10: Discusses velocity of propagation of combustion, limits of explosions, and gives curves for various combustibles, such as methane, ethane, water gas, acetylene, etc. Mar. 24: Discusses results of new investigation, including heat of combustion and heat balance.

Cooling. Improvements in the Cooling of Internal-Combustion Engines (Neuerungen in der Kühlung der Verbrennungsmotoren), H. Praetorius. Motorwagen, vol. 25, no. 9, Mar. 31, 1922, pp. 165–171, 12 figs. Discusses recent patents on the subject.

Design. Modern Tendencies in Internal-Combustion Engine Construction (Tendances modernes dans l'étude et la construction des moteurs), Edmond Bruet. Outillage, Tome 251, 252 and 253, nos. 11, 12 and 13, Mar. 18, 25 and Apr. 1, 1922, pp. 326–328, 353–356 and 374–377, 23 figs. Mar. 18: Combustion of gaseous mixtures; propagation of flame. Mar. 25: Kerosene, in internal-combustion engines (Bellem and other engines). Apr. 1: Deals with Diesel engines. Construction and operation of Sulzer two-stroke engine, the Ruston high-pressure engine, and compound Diesel engine.

Friction Losses. Friction Losses in Internal-Combustion Engines (Étude des pertes par frottements dans les moteurs à combustion interne), André Planiol. Comptes Rendus des Séances de l'Académie des Sciences, vol. 174, no. 13, Mar. 27, 1922, pp. 860–863. Gives results of experiments with four-stroke single-cylinder engine running on town-gas and develops formula for friction.

Fuel-Introduction Systems. Fuel Introduction Systems for Internal Combustion Engines. Pacific Mar. Rev., vol. 19, no. 5, May 1922, pp. 285–286, 9 figs. Description of high-pressure system developed for use with engines using accumulated type of fuel injection.

Molecular Movements During Combustion. Molecular Movements During Combustion in Closed Systems, Thomas Midgley, Jr. Soc. Automotive Engrs. Jl., vol. 10, no 5, May 1922 pp. 357–361 and (discussion) 362–363, 11 figs. Theoretical analysis of experimental work of Woodbury, Canby & Lewis published in Mar. 1921 Jl.

Photographic Recording of Data. Photographic Recording of Engine Data, Augustus Trowbridge. Soc. Automotive Engrs. Jl., vol. 10, no. 5, May 1922, pp. 351–356, 368, 12 figs. Outline of history of photographic recording apparatus and description of how it can be used to overcome difficulties with ordinary indicated diagrams.

Research. Recent Research Work on the Internal-Combustion Engine, Harry R. Ricardo. Soc. Automotive Engrs. Jl., vol. 10, no. 5, May 1922, pp. 305–328 and (discussion) 328–336 and 347, 42 figs. Discussion of fuels as to mean volatility, detonation, turbulence, stratification, and comment on benefits of weak fuel mixtures.

Still System. The Still System of Internal Combustion, F. Leigh Martineau. Can. Shipg. & Mar. Eng. News, vol. 12, no. 4, Apr. 1922, pp. 17–19. Shows that Still system can be applied to any type of internal-combustion engine without any radical alteration. Mechanical features also dealt with.

[See also AIRPLANE ENGINES; AUTOMOBILE ENGINES; DIESEL ENGINES; MARINE ENGINES; SEMI-DIESEL ENGINES.]

IRON

Melting, German Practice. Melting Iron in a German Foundry, Hubert Hermanns. Foundry, vol. 50, no. 9, May 1, 1922, pp. 367–370, 7 figs. Elabo-

rate equipment and precautions to insure suitable metal characterize methods of big Rhineland cylinder plant. Cast cylinders for original Otto gas engine.

IRON AND STEEL

Gases in. Determination of Gases in Iron and Steel (Bestimmung der Gase in Eisen und Stahl), A. Vita and Eduard Maurer. Stahl u. Eisen, vol. 42, no. 12, Mar. 23, 1922, pp. 445-452 and (discussion) pp. 452-456, 3 figs. Two reports from Chemical Committee of Assn. German Iron Met. Engrs. on process for determination of gases by means of chemical changes, and comparison of results with those obtained in extraction process by physical means.

Properties and Uses. Iron and Steel Classified for Designers, Wm. J. Merten. Blast Furnace & Steel Plant, vol. 10, no. 4, Apr. 1922, pp. 230-234, 12 figs. Survey of wrought iron, malleable iron, cast iron, and semi-steel, with special reference to physical properties, characteristics, uses and heat treatment.

IRON CASTINGS

Engines. Engine Castings Requirements Rigid, H. J. Young. Foundry, vol. 50, no. 8, Apr. 15, 1922, pp. 311-314, 18 figs. Micrographs show variation in iron in same castings, heat tends to cause Diesel-engine cylinder liners and pistons to grow: study of requirements urged. (Abstract.) Paper read before British Inst. Mar. Engrs.

Liquid Fracture in. Liquid Fracture in Iron Castings, S. G. Smith. Foundry Trade Jl., vol. 25, no. 296, Apr. 20, 1922, pp. 283-285, 7 figs. An occurrence which takes place in a casting before whole of casting has become solidified, sometimes being only microscopic and sometimes so large that it separates casting in two pieces.

IRON, PIG

Casting Methods. Questions Pig Iron Casting Methods, Robert E. Newcomb. Foundry, vol. 50, no. 8, Apr. 15, 1922, pp. 316-317. Advantages and disadvantages for foundry use of sand-cast pig iron, compared with those of pig iron made by machine casting process.

L

LAPPING

Hand and Machine. Hand and Machine-lapped Surfaces as seen through a Microscope. Machy. (Lond.), vol. 20, no. 500, Apr. 27, 1922, pp. 113-114, 6 figs. Comparison of two types of finish magnified 250 times.

LIGHTHOUSES

Aerial. Powerful Lighthouses in Aerial Navigation (Les phares à grande portée en navigation aérienne), A. Volmerange. Aeronautique, vol. 4, no. 34, Mar. 1922, pp. 67-74, 7 figs. Development of marine lights and lenses; principles of new powerful aerial lights, such as Barbier-Bénard and Sautter-Harlé; visibility of light; etc.

LIGHTING

Effective, Planning and Installing. Planning and Installing Effective Lighting, John. T. Scott. Can. Machy., vol. 27, no. 16, Apr. 20, 1922, pp. 19-20, 2 figs. Suggestions on distribution, adapting existing equipment, and reflecting surfaces by engineer in charge of standardization work at Sunbeam Lamp Wks.

Industrial. Choice of Fixtures for Industrial Lighting, John T. Scott. Can Machy., vol. 27, no. 17, Apr. 27, 1922, pp. 20-21, 3 figs. Type of reflector depends on work. Softening shadows and eliminating glare. Keep globes and lamps free from dirt. Good light prevents accident.

LIGNITE

Burning on Chain Grates. Burning Canadian Lignite on Chain Grates. Power House, vol. 15, no. 8, Apr. 20, 1922, pp. 27-28, 2 figs. Mention of several installations of Saskatchewan and Manitoba districts in which satisfactory results have been obtained. Describes typical furnace arrangement.

Deposits and Industries. Lignites and Brown Coals and Their Importance to the Empire, William Arthur Bone. Royal Soc. Arts Jl., vol. 70, no. 3619, Mar. 31, 1922, pp. 342-355 and (discussion) 355-359, 1 fig. Origin and classification, characteristics and properties, geographical distribution; brown-coal industries in various countries.

Drying. Drying of Brown Coal for Boilers and Furnaces (Rohbraunkohletrocknung für Dampfkesselfeuerungen und industrielle Oefen), W. Viebahn. Braunkohle, vol. 20, no. 51, Mar. 25, 1922, pp. 801-806, 1 fig. Discusses heat loss due to water content in brown coal and preheating of brown coal to deprive it of its water.

Gasification. Past Efforts and Future Prospects in Lignite Gasification for the Heating of Open-Hearth Furnaces (Die bisherigen Bestrebungen und die zukünftigen Aussichten der Braunkohlenvergasung für die Beheizung von Siemens-Martinöfen), Hubert Hermann. Braunkohle, vol. 20, nos. 22 and 23, Sept. 3 and 10, 1921, pp. 337-341 and 358-362, 8 figs. Economic and technical aspects of lignite gasification.

LOCKS

Manufacture. The Mechanical Principles of Modern Locks and a Consideration of their Manufacture. Machy. (Lond.), vol. 20, no. 498, Apr. 13, 1922, pp. 49-54, 12 figs. Combined lever and warded lock, with double locking bolt; function of wards and levers; automatically operated deadlock; double keyhole locks; etc.

LOCOMOTIVE BOILERS

Design. Designing Locomotive Boilers for Maximum Efficiency, J. T. Anthony. Boiler Maker, vol 22, no. 4, Apr. 1922, pp. 107-108. Air and gas areas and ratio of tube length to diameter important factors to be considered.

Standard for 2-8-0 Type. Standard Boiler for 2-8-0 Type Mixed Traffic Locomotives, Great Western Railway. Ry. Gaz., vol. 36, no. 14, Apr. 7, 1922, pp. 600-601, 3 figs. Has coupled wheels 5 ft. 8 in. in diam.; boiler is No. 7 Swinton type, barrel tapers from 6 ft. diam. outside at throat plate to 5 ft. 6 in. diam. outside at smokebox, length of barrel 14 ft. 10 in.

Tubes. Installing and Maintaining Charcoal Iron Locomotive Tubes, G. H. Woodroffe and C. E. Lester. Boiler Maker, vol. 22, no. 4, Apr. 1922, pp. 102-106, 13 figs. Use of welding in tube work and proper methods to be followed in maintenance and repair.

LOCOMOTIVES

Baldwin 2-8-0. "Consolidation" Locomotives for the Andalusian Railway, Spain. Ry. Gaz., vol. 36, no. 13, Mar. 31, 1922, pp. 553 and 556, 2 figs. Describes new Baldwin 2-8-0 type locomotive, which has unusually low coal consumption.

British and American Practice. British and American Locomotive Practice. Ry. Engr., vol. 43, no. 507, Apr. 1922, pp. 126-127. Abstract of paper presented at recent meeting of I.M.E. by P. C. Dewhurst, Loco., Carriage, and Wagon Supt. of Jamaica Govt. Rys. Closely reasoned comparisons and criticisms well worth considering.

Compound 2-8-0. New 2-8-0 Type Compound Locomotives for the Buenos Ayres Western Railway. Ry. Gaz., vol. 36, no. 16, Apr. 21, 1922, p. 676, 1 fig. Description of two-cylinder compound engine.

Design. Modern Tendencies in Locomotive Design, James Partington. Ry. Age, vol. 71, no. 15, Apr. 15, 1922, pp. 909-910 (includes discussion). Need of increased economy in use and production of steam; possibility of turbine and internal-combustion locomotives. (Abstract.) Paper presented at Newport News meeting of Am.Soc.Mech.Engrs.

Drifting Valve. Roberts Automatic Drifting Valve. Ry. & Locomotive Eng., vol. 35, no. 4, Apr. 1922, pp. 94-95, 2 figs. Object of valve is to automatically open small flow of steam to engine cylinders when throttle valve is closed, and to utilize exhaust of stoker and air pump for filling main engine cylinders as well as oil that has been fed to these auxiliaries for lubrication of cylinders.

Freight, Maximum Pull. Maximum Pull of Freight Locomotives (Essai sur les remorques maxima des locomotives à marchandises), L.-E. Creplet. Annales des Travaux Publics de Belgique, vol. 23, Feb. 1922, pp. 7-30. Describes tests with Pienlo locomotives on Kaifeng-Loyang line in China, including resistance at starting, effect of curves, etc.

Gasoline. A Gasoline Locomotive (Une locomotive a essence). Ach. Delamarre. Outillage, vol. 252, no. 12, Mar. 25, 1922, pp. 359-360, 2 figs. Describes new Renault locomotive for shunting and similar purposes in factories.

Lentz Hydraulic Transmission. "Lentz" Hydraulic Transmission for Crude-Oil Locomotives, Wittfeld. Eng. Progress, vol. 3, no. 5, May 1922, pp. 105-108, 4 figs. Internal-combustion engine burning heavy crude oil is to be adapted for locomotive service by means of Lentz hydraulic transmission. First crude-oil locomotive on this system has just been put in commission. Results of trials with this locomotive.

Steam-Electric Condensing-Turbine. New Development in Locomotive Practice. Ry. Gaz., vol. 36, no. 13, Mar. 31, 1922, pp. 557 and 564, 4 figs. partly on p. 558. Describes Ramsay condensing-turbine electric locomotive, built by Armstrong, Whitworth & Co., Ltd., tractive force, 22,000 lb.

Thermic Siphons. Thermic Syphons Save 19 Per Cent in Fuel. Ry. Age, vol. 72, no. 16, Apr. 22, 1922, pp. 977-978, 1 fig. Improved performance of ten-wheel locomotive enables Spokane International to haul heavier trains.

Test of Syphon-Locomotive on Spokane International Ry. Ry. Rev., vol. 70, no. 15, Apr. 15, 1922, pp. 522-524, 3 figs. Application of single thermic siphon enables increase in tractive effort and improves efficiency of locomotive.

Valve Gear. The Calculation and Graphical Representation of the Walschaerts Valve Gear for Locomotives, S. E. W. Westrén-Doll. Ry. & Locomotive Eng., vol. 35, no. 4, Apr. 1922, pp. 88-92, 10 figs. Describes valve and method of calculating its proportions.

The Young Locomotive Valve Gear. Ry. Jl., vol. 28, no. 4, Apr. 1922, pp. 16-21, 13 figs. Notes on original and subsequent applications, and part this valve gear is playing in successful operation on railways in United States, Canada and Mexico in passenger, freight and switching service.

LUBRICATING OILS

Crankcase Oil Dilution. Crankcase Oil Dilution Problem and Its Solution, William F. Parish. Eng. World, vol. 20, no. 5, May 1922, pp. 307-314, 11 figs. Effect upon viscosity of lubricant; viscosity limits for lubricating oils established; relation between viscosity of lubricant and efficiency of engine shown graphically in tabular form. See also Oil News, vol. 10, no. 9, May 5, 1922, pp. 33-34 and 44-46, 1 fig.

Reconditioning Crankcase. Reconditioning Crankcase Lubricating Oil by a New Method. Automotive Industry, vol. 46, no. 17, Apr. 27, 1922, pp. 910-911, 3 figs. Fuel diluent and water automatically removed from crankcase lubricating oil by simple refiner which also filters out sediment.

LUBRICATION

Uniflow Engine. Lubrication of the Uniflow Engine. Power Plant Eng., vol. 26, no. 9, May 1, 1922, pp. 477-479. Some of features which make lubrication different for this type of engine and suggestions for proper solution. (Abstract.) Lubrication, pub. by Texas Co.

M

MACHINE GUNS

Barrels, Life of. Life of Machine-Gun Barrels, W. W. Sveshnikoff. Army Ordnance, vol. 2, nos. 9 and 11, Nov.-Dec. 1921 and Mar.-Apr. 1922, pp. 161-165 and 304-307 and 316, 24 figs. Nov.-Dec.: Abrasive action of bullet and gases. Principal factors which affect life of a machine gun. Mar.-Apr.: Cracking of surface of bore. Extracts from Technologic Papers Bur. Standards, No. 191.

Carriages and Mountings. Ordnance and Machine-Gun Carriages and Mountings. Abridgments of specifications, Period 1909-15, Class 92 (i), 1922, 277 pp. Patents for inventions.

MACHINE SHOP

Field Shop. A Field Shop in the Oil District, Frank A. Stanley. Western Machy. World, vol. 13, no. 4, Apr. 1922, pp. 120-122, 8 figs. Description of well-equipped shops maintained in Signal Hill Oil fields by Shell Co.

MACHINE TOOLS

Chain Drive. The Chain Drive and Machine Tools, Hubert Bentley. Mech. World, vol. 71, nos. 1838 and 1839, Mar. 24 and 31, 1922, p. 215 and pp. 235-236, 3 figs. Mar. 24: Compares chain with belt and gear drives; advantages of chain drive. Mar. 31: Types of chains and wheels; chain driving and installation and maintenance of chain drives.

German Construction. Progress in German Machine-Tool Construction (Fortschritte im deutschen Werkzeugmaschinenbau), Werner v. Schütz, G. Schlesinger and Max Kurrein. Werkstattstechnik, vol. 16, nos. 4a and 5, special no. and Mar. 1, 1922, pp. 1-62 and 129-156, 121 figs. Metal-working machines, including lathes, grinding, planing and slotting, boring and milling machines. Mar. 1: Hammers, shears, presses, bending machines and saws. Woodworking machines. Special machines. Tools, devices and finishing processes.

MALLEABLE IRON

Structure. Structure of White-Heart Malleable, Rudolph Stotz. Foundry, vol. 50, no. 7, Apr. 1, 1922, pp. 286-290, 25 figs. Principal characteristics shown by micrographs which indicate over or under annealing; carbon contents determine structure of unannealed iron.

MARINE BOILERS

Economy. Possibilities of Further Economy in Marine Boilers, John Reid. Shipbldg. & Shipg. Rec., vol. 19, no. 15, Apr. 13, 1922, pp. 461-465, 7 figs. Suggestions of remedies for heat losses and result of boiler trials at St. Peters Works, Hawthorne, Leslie & Co.

Possibilities of Further Economy in Marine Boilers, John Reid. Steamship, vol. 33, no. 395, May 1922, pp. 365-368, 4 figs. Data acquired from instruments installed in steamers suggests possibilities of new economies. Paper read at Spring Mtg. of Inst. of Naval Architects.

MARINE ENGINES

Sulzer Two-cycle. The Sulzer Two-Cycle Marine Engine, L. J. Le Mesurier. Oil Eng. & Finance, vol. 1, no. 2, Mar. 25, 1922, pp. 372-373. Advantages of two-cycle type above 1000 b.hp. (Abstract.)

MARINE STEAM TURBINES

Economy. Modern Marine Steam Turbine Economy. Mar. Engr. & Naval Architect, vol. 45, no. 535, Apr. 1922, pp. 165-167, 4 figs. Land and marine turbines compared. Direct drive versus reduction-geared turbines. Effect of higher gearing ratio and increased turbine revolutions on efficiency.

MATTER

Molecules, Space Between. The Space Between Molecules (Ueber den Abstand der Molekeln), Richard Gans. Physikalische Zeit., vol. 23, no. 5, Mar. 1, 1922, pp. 108-113, 4 figs. Derivation of equations for determining average space between molecules.

MEASURING INSTRUMENTS

Aircraft. Aircraft Measuring Instruments (Messgeräte für Flugzeuge), E. Everling and H. Koppe. Zeit. des Vereines deutscher Ingenieure, vol. 66, no. 13, Apr. 1, 1922, pp. 322-326, 29 figs. Points out that vibrations, quick change of flight and air conditions, and effect of wind necessitate special arrangement and construction of instruments, which is demonstrated by examples of indicating and recording instruments for pressure, change of altitude temperature, and for inclination and turning speed.

Precision. Precision Work in the National Physical Technical Institute (Die Feinmechanik in der Physikalischen-Technischen Reichsanstalt), F. Göpel. Zeit. des Vereines deutscher Ingenieure, vol. 66, no. 13, Apr. 1, 1922, pp. 293-298, 5 figs. Review of work in laboratory for precision measuring, with special regard to technically important work. Deals with equipment and measuring methods, especially of technical gage blocks, pass bolts and gages, guide screws and standard threads, revolution counters, tuning forks, etc.

METAL SPRAYING

Schoop Process. Metal Spraying, An Anti-Rust Prophylactic. Raw Material, vol. 5, no. 4, May 1922, pp. 147–149, 4 figs. By Schoop process iron, steel, and non-metallic materials are given non-ferrous metal coatings through device resembling machine gun that bombards objective surface with minute plastic particles of metal.

METALS

Protection from Air and Heat. Protecting Metal From Air and Heat—Calorizing (La protection des metaux contre les agents atmospheriques et la chaleur—La calorisation ou protection par l'aluminium), R. Levatel. Outillage, vol. 254, no. 14, Apr. 8, 1922, pp. 412–413. Reviews the Bower-Barff, Gesner, Lohman, Schoop and sherardizing processes. Bibliography.

Polishing. Motion Study in Metal Polishing, E. Farmer and R. S. Brooke. Metal Industry (N. Y.), vol. 20, no. 4, Apr. 1922, pp. 133–136, 3 figs. Experiment with wattmeter on process of roughing.

Tempering. The Tempering Phenomena and Their Generalization (Les phénomenes de trempe et leur généralisation), De Perdiguier. Chimie et Industrie, vol. 7, no. 2, Feb. 1922, pp. 211–243, 32 figs. Discusses critical points in temperature diagrams, including the cases of, eutectoids, line of transformation separating zone of one constituent from zone of two constituents, and zone of two constituents with two irregular lateral boundaries.

Tempering Phenomena and Their Generalization (Les phénomènes de trempe et leur géneralisation), Léon Guillet. Révue de Métallurgie, vol. 19, no. 3, Mar. 1922, pp. 162–168, 13 figs. On basis of diagram discusses the three cases of (1) eutectoid, (2) line of transformation separating zone of one constituent from zone of two constituents, and (3) zone of two constituents bounded laterally by two irregular lines.

MILLING MACHINES

Vertical, Economy of. Examples Where Vertical Milling Saved Money, J. H. Moore. Can. Machy., vol. 27, no. 16, Apr. 20, 1922, pp. 17–18, 46, 5 figs. Suitable fixtures facilitate production; multi-tooth cutters replace single point tool; particularly adapted to die-sinking; special attachments for continuous milling.

MOLDING MACHINES

Portable Hand-Operated. Exhibits a German Molding Machine. Foundry, vol. 50, no. 8, Apr. 15, 1922, pp. 324–325, 5 figs. Describes portable, hand-operated machine of Vereinigte Schmirgel & Maschinenfabriken, A. G., recently exhibited at Liege, Belgium.

MOLDING METHODS

Production. Fittings Made on Production Basis. Foundry, vol. 50, no. 9, May 1, 1922, pp. 359–365, 9 figs. Adoption of simple and precautionary molding devices in shape of lifting plates and core prints reduce molding costs and insure more uniform product.

MOLYBDENUM STEEL

Automotive Industry. Use of Molybdenum Steel in the Automotive Industry, John D. Cutter. Soc. Automotive Engrs. Jl., vol. 10, no. 5, May 1922, pp. 340–342 and (discussion) 342–344 and 347, 2 figs. Advantages in connection with light-weight car including reports and statements of metallurgists and manufacturers.

MONEL METAL

Properties and Uses. Monel Metal, a Natural Nonferrous Alloy, Morris A. Hall. Brass World, vol. 18, nos. 3 and 4, Mar. and Apr. 1922, pp. 76–79, 107–111, 18 figs. Appearance and properties; proper methods of melting and casting; uses and advantages.

MOTOR BUSES

Easy-Riding Tires. Easy Riding on Heavy Motor Vehicles. Bus Transportation, vol. 1, no. 5, May 1922, pp. 277–280, 15 figs. How tire and felloe construction provide comfort for passengers and longer life for bus mechanism.

High-Speed Design. High-Speed 'Bus Design. Motor Transport, vol. 34, no. 895, Apr. 24, 1922, pp. 500–501, 5 figs. Unusual body and chassis features embodied in vehicle built for Inter-city work in California, where high speeds are possible.

Trolley. Some Details of the "Rail-less" Car. Bus Transportation, vol 1, no 5, May 1922, pp. 268–269, 5 figs. Two-motor trolley bus with series-parallel control, seating capacity is thirty persons, with provision for liberal space and conveniences for several standees.

Trolley Bus Line Material and Current Collectors, G. W. Bower. Bus Transportation, vol. 1, no 5, May 1922, pp. 281–282, 6 figs. Result of experience shows that design of suspension and collectors must coördinate.

MOTOR TRUCKS

Gas Producers. The Cazes Gas Producer for Motor Trucks (Le gazogène "Cazes" pour camion automobile), E. Weiss. Nature, no 2501, Mar. 11, 1922, pp. 145–147, 3 figs. Describes producer-gas generator of 30–40 hp. consuming 483 gr. charcoal per hp. and pulling trucks of nearly 12 tons.

Tipping. New Motor Trucks for Conveying Quantity Goods (Neuere Lastkraftwagen für die beförderung von Massengütern), L. Ptaczowsky. Allgemeine Automobile Zeitung, vol. 23, no 9, Mar. 4, 1922, pp. 38–40, 9 figs. Describes various types of Krupp tipping trucks; unloading sideways, on all sides, into railroad cars; etc.

MOTORCYCLES

Engines. Motor Cycle Engines. Automobile Engr., vol. 11, nos. 154 and 155, Sept. and Oct. 1921, pp. 299–300, 10 figs. and pp. 353–355, 4 figs. Sept.: Describes power units of Indian "Scout" Engine built by Hendee Mfg. Co. Oct.: Power units of J. A. Prestwich single cylinder and twin engines.

Single Sleeve-Valve Engine. The Barr and Stroud 3 Hp. Cycle Engine. Automobile Engr., vol. 12, no. 162, Apr. 1922, pp. 115–117, 7 figs. Features of recently developed Knight type motor.

N

NATURAL GAS

Combustion Tests. Natural Gas Combustion Tests, I. V. Brumbaugh and G. W. Jones. Gas Age-Rec., vol. 49, no. 16, Apr. 22, 1922, pp. 495–498, 2 figs. Associate Gas Engr. and Asst. Chemist of U. S. Bur. of Standards give, with permission, advance information on their tests of natural gas used in domestic gas burners.

NICKEL ALLOYS

Cooperite. Cooperite, a High-Speed Cutting Material. Raw Material, vol. 5, no. 3, Apr. 1922, pp. 110–112, 4 figs. Discusses properties of and tests made with cooperite, a non-ferrous alloy containing nickel as basic metal with various amounts of zirconium, aluminum, silicon, tungsten and molybdenum.

Nickel-Silver. Some Mechanical Properties of the Nickel-Silvers, F. C. Thompson and Elwin Whitehead. Metal Industry (Lond.), vol. 20, nos. 11 and 12, Mar. 17 and 24, 1922, pp. 249–254 and pp. 276–277 and (discussion) p. 280, 17 figs. Effect of conditions of annealing on tensile properties of hard-rolled alloys; temperature of heating and rate of cooling of three alloys containing 10, 15 and 20 per cent of nickel; results of tests. Paper read before Inst. Metals.

NOTCHED-BAR TESTS

Investigation of. The Notched-Bar Test (Die unerforschte Kerbschlagprobe), R. Stribeck. Stahl u. Eisen, vol. 42, no. 11, Mar. 16, 1922, pp. 405–408, 1 fig. Desiderata for new development. Notched-bar test for testing of workshop material. Author advises precaution in judging materials tested in this manner. Suggestions for a new regulation.

O

OIL FUEL

Laundry Power Plant. Oil Burning in Laundry Power Plant, Charles L. Hubbard. Nat. Engr., vol. 26, no. 5, May 1922, pp. 192–196, 9 figs. Oil substituted for coal and shows decided advantages; equipment details.

Naphtha, Calorific Power of. Indirect Determination of Calorific Power of Naphtha as a Fuel (Determinazione indiretta del potere calorifico della nafta per uso di combustibile), Giulio Morpurgo. Giornale di Chimica Industriale ed Applicata, vol. 4, no. 1, Jan. 1922, pp. 15–17. Discusses new method for analyzing liquid fues, which requires no complicated apparatus, and gives rational basis for evaluating naphtha.

Pools, Beds, or Streams. Pools or Beds, Streams of Oil? J. von Gal Scale. Petroleum Times, vol. 7, no. 172, Apr. 22, 1922, p. 560. Pointing out misleading character of term pool.

OIL INDUSTRY

Bergin Treatment. The Bergin Treatment of Mineral Oils and Coal, F. Bergin. Petroleum Times, vol. 7, no. 172, Apr. 22, 1922, p. 516. Description of process by which mineral oils and coal can be converted into benzine, motor spirit, and fuel oil. Presented at Assn. of German Chemists' recent meeting.

OILS

Specifications for Fats and. Oils, Fats, Lubricants, Candles, and Soaps. Abridgments of Specifications, Period 1909–15, Class 91, 1922, 151 pp. Patents for inventions.

OPEN-HEARTH FURNACES

Operation. Efficient Arrangement of Open Hearth Labor, P. S. Young. Blast Furnace & Steel Plant, vol. 10, no. 4, Apr. 1922, pp 215–219. Reduction of forces by better distribution of men and occupations in operating modern open-hearth shop.

Valves, Reversing. New Reversing Valves for Open Hearth Furnaces, Hubert Hermanns. Blast Furnace & Steel Plant, vol. 10, no 4, Apr 1922, pp 228–229, 4 figs. Describes new bell valve, consisting of two parts which are separated by water-cooled partition wall.

OXY-ACETYLENE WELDING

Railway Shops, In. The Oxy-Acetylene Process in Railway Shops, F. S. Tinder. Car Foremen's Assn. of Chicago. Official Proc., vol 17, no. 6, Mar. 1922, pp. 16–39 and (discussion) pp. 40–57, 2 figs. Notes on properties of acetylene and oxygen; development of process. Experience in welding on Virginian railway.

Safe Handling. Gas Welding and Cutting. Am. Gas Jl., vol 116, no. 14, Apr. 8, 1922, pp. 328–330 and 336–338. Rules for safe handling of apparatus.

P

PAINTS

Protection for Wood. Paint Protection for Wood, Cornelius R. Myers. Soc. Automotive Engrs. Jl., vol. 10, no. 5, May 1922, pp. 348–350, 2 figs. Report of investigation resulting from complete lack of data on protection of wood against moisture.

Specifications. Why Paint Specifications Present a difficult Problem, F. P. Ingalls. Ry. Rev., vol. 70, no. 17, Apr. 29, 1922, pp. 597–600, 1 fig. Effect of character of pigment on drying and durability of paint; effect of size and shape of pigment particles on character of paint. Satisfactory specifications cannot be based on composition but on what paint will do. From paper presented at Nat. Expos'tion of Chem. Industries, in N. Y.

PAPER MANUFACTURE

Deodorizing Digester Blow. Removal of Odors from Digester Blow in Sulphate Mills, Gustaf F. Enderlein. Paper Mill, vol. 45, no. 16, Apr. 29, 1922, pp. 4, 1 fig. Suggestions as to means of avoiding poluting atmosphere by condensing odoriferous steam.

Developments. Recent Developments in Paper-making, T. D. Nuttall. Paper, vol. 30, no. 6, Apr. 12, 1922, pp. 7–11 and 16. Forming sheet and felting fibers on high speed machines of great width. From Proc. Technical Section of Papermakers' Assn. Great Britain and Ireland.

Explosion of Drying Cylinder. Explosion of a Drying Cylinder (Zerknall eines Trockenzylinders). Zeit. des Bayerischen Revisions-Vereins, vol. 26, no. 7, Apr. 15, 1922, pp. 51–52, 4 figs. Describes explosion at cellulose factory in Silesia; cylinder was part of a paper-making machine running 300 days of 24 hr. per year; exact cause has not been ascertained.

Latex. Making Paper with Latex, Frederick Kaye. Rubber Age, vol. 3, no. 2, Apr. 1922, pp. 67–68. Comparison of quality of product with and without this rubber derivative.

PAPER MILLS

Ventilation. Moving Air in Paper Mill Work, Paper, vol. 30, nos. 4, 5 and 7, Mar. 29, Apr. 5 and 19, 1922, pp. 7–11, 8–11 and 128–131. Mar. 29: Altering pressure of air; overcoming moisture from wet machines; types of finishing rooms to be ventilated; maintaining even humidity conditions; heating system for machine room; distributing the air. Apr. 5: Utilization of waste heat; use for air in plants making coated paper; regulating temperature of press rooms. Apr. 19: Methods of conditioning gummed paper; dryers; conditioning air in storage buildings.

PATENT LAWS

Germany. Inventions and Patent Rights (Maschinenerfindungen und Patentrecht). Dinglers polytechnisches Journal, vol. 337, no. 7, Apr. 8, 1922, pp. 65–66. Discusses requirement of novelty for German patents as laid down by recent legal decisions.

PATTERNS

Foundry, Design. Pattern Design Presents Problems, Joseph Horner. Foundry, vol. 50, nos. 7 and 8, Apr. 1 and 15, 1922, pp. 275–278 and 326–328, 25 figs. Apr. 1: Coöperation between heads of manufacturing enterprise will prevent annoying and costly mistakes. Apr. 15: Pattern construction costs from pattern-shop viewpoint and from foundry and machine-shop viewpoint.

PIPE

Threading and Cutting Machine The Landis Twelve-Inch Pipe Threading and Cutting Machine. Ry. & Locomotive Eng., vol. 35, no. 4, Apr. 1922, pp. 83–85, 6 figs. Length of machine is 11 ft., its extreme width, 5 ft. and it weighs 13,000 lb.; it has single-pulley drive, and variations in speed, which are eight in number, are obtained by means of speed box, located beneath main spindle.

PIPING

Losses, Calculation of. Calculating Losses in Air and Steam Conduits According to New Research on the Coefficient of Resistance to Flow (Calcul des pertes de charge dans les conduites d'air, de vapeur et d'eau d'après de nouvelles recherches sur le coefficient de résistance à l'écoulement), V. Leveau. Révue Universelle des Mines, vol. 12, no. 4, Feb. 15, 1922, pp. 301–327, 10 figs. partly on supp. plate. Reviews literature on subject, calculates pressure losses, classifies pipe by roughness, and gives examples of applying new formulas.

PISTONS

Aluminum Alloys for Motor. Some Experiences of Aluminium and Its Alloys for Motor Pistons. Metal Industry (Lond.), vol. 20, no. 14, Apr. 7, 1922, p. 321. Advantages obtained from pistons of this type and analyses of more suitable combinations.

Cast Iron, Production. Methods Used in Specialized Production of Cast Iron Pistons, J. Edward Schipper. Automotive Industries, vol. 46, no. 17, Apr. 27, 1922, pp. 914–916, 6 figs. Some original processes. Foundry cores are machine-made. Description of aging process, machining and inspection methods. Claimed that pistons are held to tolerance of plus or minus 0.0005 in.

PLANERS

Spur-Gear. Planing Large Spur Gears. Machy. (Lond.), vol. 20, no. 498, Apr. 13, 1922, pp. 37–39, 5 figs. Application of gear planers which cut gear teeth by reproducing shape of a templet.

PLATES

Deflection. The Deflection of Continuous Plates and the Rectangular Plate with Free Edges (Ueber die Biegung durchlaufender Platten und der rechteckigen Platte mit freien Rändern) A. Nadai. Zeit. fur angewandte Mathematik u. Mechanik, vol 2, no. 1, Feb. 1922, pp 1-26, 24 figs. Calculations to determine singularities of plate deflection.

POWER PLANTS

British Practice. Notes on British Power Plant Practice, C. H. S. Tupholme. Power Plant Eng., vol 26, no. 8, Apr. 15, 1922, pp. 416-418. Experiments with peat, discussion of methods of improving internal-combustion engine efficiency.

Construction, Far East. Dredge and Power Plant Construction in the Far East, P. R. Parker. Eng. & Min. Jl.-Press, vol. 113, no. 119, May 13, 1922, pp. 807-812, 7 figs. Equipment purchased in U. S., modeled on California gold practice, a success in dredging for stream tin in Malay states, difficulties of transportation and installation solved.

Cost Cutting in Industrial. Cost Cutting for Industrial Power Plants, David Moffat Myers. Indus. Management, vol. 63, nos. 3, 4 and 5, Mar., Apr. and May 1922, pp. 140-142 and 170, 234-237, 304-309, 4 figs. Mar.: How to discover and correct boiler-plant wastes. Apr.: Determining present results and possible improvements. May: Methods of improving performance.

Design. Developments in Power Station Design. Engineer, vol. 133, no. 3457, Mar. 31, 1922, pp. 347-350, 9 figs. Describes condensers and their auxiliaries put on market by G. & J. Weir, Ltd., Glasgow, Scotland.

Five Pacific Coast Projects. Five Pacific Coast Water-Power Projects Licensed by Commission. Elec. World, vol. 79, no. 17, Apr. 29, 1922, pp. 850. Plants at Kaweah River outside Sequoia Nat. Park, on San Joaquin River in Fresno and Madera Counties, on Snow Creek, Riverside County, at Delta, Cal., and on Clackamas River, Clackamas County, Oregon, to be developed.

Industrial, Layout for. Laying Out a Power and Heating System for an Industrial Plant, Chas. L. Hubbard. Southern Engr., vol. 37, no. 3, May 1922, pp. 47-51, 7 figs. Piping layout from boiler to engine and pumps, heating system, supply and return and fire protection.

Operation. Higher Steam Pressures or Pulverized Coal? Frederick A. Scheffler. Am. Inst. Elec. Engrs. Jl., vol. 41, no. 5, May 1922, pp. 346-350, 1 fig. Assumes a hypothetical power or public service steam plant of 100,000-kw. nominal capacity and compares cost of operation of such a plant oo basis of 250 lb. pressure and 600 deg. fahr. total steam temperature, and 400 lb. pressure and 700 deg. fahr. total steam temperature, when fired by stokers aod pulverized coal.

Sweden. Swedish State Power Plants (Die Kraftwerke des schwedischen Staates). Elektrotechnischer Anzeiger, vol. 39, nos. 57-58 and 59, Apr. 12 and 13, 1922, pp. 491-492 and 501-502, 6 figs. Construction and equipment of Motala power station recently opened, which, in conjunction with power stations at Trollhättan, Alfkarleby and Porjus, supplies power to state railways and various industries.

Utica State Hospital. Power and Heating Plant of Utica State Hospital. Power Plant Eng., vol. 26, no. 9, May 1, 1922, pp. 449-456, 12 figs. Description of central installation to supply heat, light, water, and power for institution approaching proportions of a city.

POWER TRANSMISSION

Oil. Power Transmission by Oil (Elaulic Gear), H. S. Hele-Shaw. Oil Eng. & Finance, vol. 1, no. 1, Jan. 14, 1922, pp. 59-68, 16 figs. Description of oil-variable-gear which is newest of special type.

Rope Drive. Power Transmission by Rope Drive, A. D. Wilkinson. Southern Engr., vol. 37, no. 3, May 1922, pp. 35-37, 5 figs. Many textile mills are driven by means of rope-drive system. Multiple drive is dealt with in this article.

Types of Drives. Progress and Problems in Mechanical Transformation of Energy (Fortschritte und Probleme der mechanischen Energie-Umformung), K. Kutzbach. Zeit. des Vereines deutscher Ingenieure, vol. 66, nos. 7 and 8, Feb. 18 and 25, 1922, pp. 154-159 and 183-185, 26 figs. Deals with indirect converter types. Status of belt and rope drive for long-distance conversion; increasing use of stretching pulleys for safe control of external tensions, problem of slip and friction, durability and bending losses. The Föttinger and the Lentz converters and their use for all kinds of vehicles.

PRESSES

Inclinable. The Use of Inclinable Power Presses. Machy. (Lond.), vol. 19, no. 496, Mar. 30, 1922, pp. 737-738, 3 figs. Inclination of presses; classes of work readily performed on inclinable presses.

PULLEYS

Driving for Hydro-Extractor. Driving Pulley for Hydro-Extractor. Textile World, vol. 61, no. 16, Apr. 22, 1922, p. 41, 3 figs. Centrifugal clutch pulley which does not put load on motor until it has attained good speed.

PULVERIZED COAL

Combustion. The Carrying of Dust by a Current of Air (Etude de l'entrainement de poussièrepar un courant d'air), R. Audibert. Annales des Mines, vol. 1, no. 3, Mar. 1922, pp. 153-191, 3 figs. Discusses question of pulverized coal, especially arrangement of combustion chamber so as to assure complete combustion of dust.

Office-Building Heating. Powdered Fuel. Nat. Engr., vol 26, no. 5, May 1922, pp 219-221, 1 fig. Results from installation in 42-story L. C. Smith building, Seattle, Wash.

Power Plants. Lakeside Power Station at Milwaukee. Power Plant Eng., vol. 26, no. 8, Apr. 15, 1922, pp. 397-406, 12 figs. Mechanical, electrical and construction features of world's largest pulverized fuel burning power plant.

Steam Boilers for. Powdered Coal under Steam Boilers, H. D. Savage. Coal Trade Jl., vol. 52, nos. 36, 37, 38, 39, 40 and 41, Sept. 7, 14, 21, 28, Oct. 5 and 12, 1921, pp. 1003-1004, 1028-1029, 1049-1051, 1074, 1094-1095 and 1116-1117, 5 figs. Progress made in making powdered coal for steam production thoroughly reliable and efficient, and economic possibilities of this method of combustion.

Treatment and Use. A New Pulverised Fuel Plant. Iron & Coal Trades Rev., vol. 104, no. 2821, Mar. 24, 1922, pp. 418-419, 2 figs. Describes coal drier, conveyance and distribution of pulverized fuel, hopper and controller system.

PUMPS

Semi-Solid Handling. A Pump that Handles Semi-Solids. Elec. News, vol. 31, no. 9, May 1, 1922, p. 51, 2 figs. Particularly designed to pass unscreened sewage; rags, cotton waste, fiber and all kinds of pulp and trade effluent from textile works in general. Made in England.

PUMPS, CENTRIFUGAL

Balancing, Automatic Method. Centrifugal Pumps, E. T. Keenan. Southern Engr., vol. 37, no. 3, May 1922, pp. 40-43, 7 figs. Automatic method of balancing; efficiency and losses.

PYROMETERS

Non-Ferrous Foundry. Pyrometry in the Non-Ferrous Foundry. Eng. Production, vol. 4, no. 81, Apr. 20, 1922, p. 365, 1 fig. Notes on thermo-electric, resistance, radiation and optical pyrometers.

R

RAILS

Russian 95-lb. The New 47 kg/m Rails of the Russian State Railways (Neue 47 kg/m schwere Schiene der russischen Staatsbahnen), C. Oppenheim. Organ fur die Fortschritte des Eisenbahnwesens, vol. 77, no. 3, Feb. 1, 1922, pp. 38-39, 2 figs. Describes in detail profiles of these new rails intended for very heavy traffic, and compares with rails in other countries.

Deformation, Measuring. Measuring Rail Deformation by Moving Picture Photography. Ry. Rev., vol. 70, no. 14, Apr. 8, 1922, pp. 483-484, 6 figs. partly on p. 485. Describes method for making observations of rail depression under a moving load by means of moving picture camera, and gives results of series of tests made on St. Louis-San Francisco Ry.

Steel, Rolled Manganese. Rolled Manganese Steel Rails. Ry. Gaz., vol. 36, no. 14, Apr. 7, 1922, pp. 597 and 601, 2 figs. Advantages claimed for built-up railway track work. Discusses layout of "Imperial" patent rolled manganese steel rails of Waterloo Station, Lond. & South Western Ry.

RAILWAY ELECTRIFICATION

Inductive Interference and Electrolysis. The Question of Inductive Interference and Electrolysis Relating to Railroad Electrification, Chas. F. Scott. Elec. Jl., vol. 19, no. 4, Apr. 1922, pp. 146-149. Consideration of various ways in which telephone service has been interfered with and pipe lines corroded, and means of overcoming difficulties.

Italy. Electrification of the Italian Railways (L'Elettrificazione delle Ferrovie Italiane), C. Vita-Finzi. Elettricista, vol. 4, nos. 5 and 6, Mar. 1 and 15, 1922, pp. 37-38 and 44-46, 1 fig. Discusses electric traction, and necessity for Italy to electrify; new law for electrification of railroads. Gives list of trunk lines already electrified and list of lines to be electrified.

Single-Phase Overhead System. The Lancaster-Morecambe-Heysham Electric Railway. Electrician, vol. 88, nos. 2281 and 2282, Feb. 3 and 10, 1922, pp. 124-129 and 155-156, 8 figs. Experiences of 14 years' working with single-phase overhead system. Failures and modifications which have been necessary in various parts of apparatus during the 14 years.

RAILWAY MOTOR CARS

New Features. New Features in Service Railway Motor Coach. Ry. Age, vol. 72, no. 18, May 6, 1922, pp. 1069-1070, 3 figs. Service Motor Truck Co., Wabash, Ind., produces coach in which power plant and transmission follow regular motor truck practice but running gear is unique.

Operating Costs. Motor Trucks Operate on Rails in City and Interurban Passenger Service. Mun. & County Eng., vol. 62, no. 4, Apr. 1922, pp. 18-22, 1 fig. City and Interurban Ry. Co., Manhattan, Kansas, has recently scrapped heavy electric cars and now operate four FWD railway cars.

Problems. Modern Motor Rail Cars and the Local Passenger Problem, L. G. Plant. Ry. Rev., vol. 70, no. 15, Apr. 15, 1922, pp. 519-522, 2 figs. General problems involved in successful adaptation of modern rail car to steam railway service.

RAILWAY OPERATION

Auxiliary Train Control. The Sprague System of Auxiliary Train Control. Ry. Age, vol. 72, no. 16, Apr. 22, 1922, pp. 963-967, 9 figs. Apparatus undergoing daily test on section of New York Central operates on normal danger plan and leaves engineer practically undisturbed while on duty.

Reversible Steam Train. "Reversible" Steam Train, London & North Western Railway. Ry. Gaz., vol. 36, no. 17, Apr. 28, 1922, pp. 697-699, 5 figs. Describes push-and-pull train which has been working satisfactorily on local service in England.

Train Control. Automatic Train Control in America. Ry. Gaz., vol. 36, no. 16, Apr. 21, 1922, pp. 658. Some observations on Interstate Commerce Commission suggestions in accordance with Sec. 26 of Transportation Act advising full equipment over one passenger division by July 1, 1924.

Railroads Argue Against Automatic Stops at I. C. C. Hearing. Ry. Signal Engr., vol. 15, no. 4, Apr. 1922, pp. 151-158. Railroads claim that no automatic train stop or train control device has been sufficiently developed to warrant installation on such extensive scale as is outlined in proposed order of Interstate Commerce Commission and that Am. Ry. Assn. is working for development of a practical device.

RAILWAY REPAIR SHOPS

Freight Cars. Rip Track Equipment and Methods on Ft. D. D. M. & S. Ry. Rev., vol. 70, no. 14, Apr. 8, 1922, pp. 491-495, 11 figs. Equipment and management of new freight-car repair yard and methods of repairing.

RAILWAY SHOPS

Equipment. What Shop Equipment Means to a Railroad, V. Z. Caracristi. Central Ry. Club Official Proc., vol. 30, no. 2, Mar. 1922, pp. 1156-1167 and (discussion) 1168-1182, 2 figs. Discusses expenditures necessary to take care of locomotives and cars coming immediately under jurisdiction of motive power department; gives charts and tables.

RAILWAY SIGNALING

Belgium. Signaling on the Belgian State Railways (La signalisation des chemins de fer de l'état Belge), Lucien Pahin. Génie Civil, vol. 80, no. 11, Mar. 18, 1922, pp. 253-255, 3 figs. Describes fixed signal system, positions of arms, colored lights, and shows how dangerous points are guarded by signals.

Facing Points, Long-Distance Operation. Long-Distance Operation of Facing Points. Ry. Gaz., vol. 36, no. 13, Mar. 31, 1922, p. 561, 3 figs. Relates how colliery company has been first in England to work facing points 500 yards distant direct from signal box electrically by primary batteries, providing ready and comparatively cheap means towards converting refuge sidings into running loops.

Unlocking by Tablet. Unlocking the Starting Signal for Entering a Single Line Section by the Tablet. Ry. Engr., vol. 43, no. 507, Apr. 1922, pp. 133-139, 1 fig. Only railway company which consistently unlocks all single line starting signals by tablet is London & South-Western. Description of original and present method employed.

RAILWAY TIES

Tamping Machine. Tamping Machine for Railroad Ties (Machine para soccar o lastro sob os dormentes). Revista Brasileira de Engenharia, vol. 3, no. 2, Feb. 1922, pp. 79-80, 2 figs. Describes machine made by Serva & Cia., S. Paulo, consisting of a hammer for tamping ballast and a gasoline engine for driving hammer.

RAILWAY TRACK

Construction. Adjusting Track Construction to the Lightweight Car, R. G. Taber. Elec. Ry. Jl., vol. 59, no. 18, May 6, 1922, pp. 755-756, 1 fig. Account of two track jobs recently completed in Fort Worth, in which advantage was taken of light weight of Birney cars operated there in cheapening construction. (Abstract.) Paper read before Southwestern Elec. & Gas Assn.

Curves. The Design of Transition Curves for Railway Tracks (Zur Konstruktion des Uebergangsbogens fur Eisenbahngleise), K. Lachmann and R. Rothe. Zeit. fur angewandte Mathematik u. Mechanik, vol. 2, no. 1, Feb. 1922, pp. 45-78, 8 figs. It is claimed that methods of practical mathematics permit accurate solution of problem, not only for flat curves, but for transition curves for any given differences in direction.

Rack Type. Rack Wheel and Branch Lines (Zahnradanschlussbahnen), A. Wichert. Schweiz. Elektrotechnischer Verein Bul., vol. 13, no. 3, Mar. 1922, pp. 98-106, 6 figs. Describes cog-wheel electric locomotive of Oker Metal and Color Works, in Harz Mountains, and loading and unloading arrangements at works with a difference in levels of 24 meters.

Shifting Machine. Track Shifting Machine, Friedr. Hübener. Eng. Progress, vol. 3, no. 4, Apr. 1922, p. 87, 2 figs. Describes Arbenz-Kammerer type, consisting essentially of portable bridge resting on two bogies; center of bridge carries frame which may be shifted over laterally.

RAILWAYS

Czechoslavakia. The Railways of Czechoslavakia (Trois années d'existence des chemins de fer Tchécoslovaques), Paul Koller. Révue Générale des Chemins de Fer et des Tramways, vol. 41, no. 4, Apr. 1922, pp. 276-290, 1 fig. Discusses post-war situation, rolling stock, workshops, coal shortage, finances, etc.

Chinese Government. Administration of Chinese Government Railways, Ching-chun Wang. Ry. Rev., vol. 70, no. 17, Apr. 29, 1922, pp. 600-605, 2 figs. Railway developments in China and details of Central Administration controlling them. From Jl. Assn. Chinese & Am. Engrs.

Italy. Italian Railways. Ry. Gaz., Special Italian Railway Number, Apr. 18, 1922, pp. 5-32, 102

figs. partly on pp. 33–69. (In Italian and English.) Detailed description of state railways, including administrative management and staff, passenger fares and train service, freight traffic, engineering questions, rolling-stock, etc.

Russia. Present State of Railroad Transportation in Russia, U. I. Lebedeff. (In Russian.) Supp. to Eng. News of Scientific and Technical Council of Russian Eng. Assn., Jan. 1919, 8 pp., 12 figs. Statistical data on Russian railroads as they were at end of 1918.

REFRACTORIES

Softening Temperature, Determining. A New Device for Determination of the Softening Temperature of Refractory Materials under Load (Eine neue Vorrichtung zur Bestimmung der Erweichungstemperatur von feuerfesten Materialien unter Belastung), W. Steger. Berichte der Deutschen Keramischen Gesellschaft, vol. 3, no. 1, Feb. 1922, pp. 1–4, 1 fig. Describes press and heating device developed by author for use in Chemical-Technical Experimental Station of the State Porcelain Mfg. Works, Berlin-Charlottenburg.

REFRIGERATING MACHINES

Carbon Dioxide. The Operation of CO_2 Marine Refrigerating Machines in Warm Seas (Du fonctionnement des machines frigorifiques marines a acide carbonique dans les mers chaudes). Bul. Technique du Bureau Veritas, vol. 4, no. 2, Feb. 1922, pp. 43–44, 1 fig. Difficulties arising from fact that critical point of CO_2 is 31.35 deg. and temperature in warm seas sometimes is above 30 deg., and describes Le Blanc method of overcoming difficulties, consisting simply of cooling condensing water by installing between sea and condenser of CO_2 machine, a vacuum evaporator.

REFRIGERATING PLANTS

Ammonia Fittings, Standardization of. Standardization of Ammonia Fittings Necessary, Erwin Bunzel. Power, vol. 55, no. 15, Apr. 11, 1922, p. 581. Pointing out necessity of early adoption of code covering standardization of flanges for refrigerating systems.

REFRIGERATION

Meat Industry. Refrigeration and the Meat Industry, W. H. Medcalf. Cold Storage & Ice Assn. Proc., vol. 18, no. 1, 1921–22, pp. 69–83 and (discussion) pp. 84–90. Indicates general uses to which refrigeration is applied at present time.

ROLLING MILLS

Electric Drive Troubles. Where to Look for Things that Cause Trouble in Reversing-Roll Electric Drives, Arthur J. Whitcomb. Elec. Rev. & Indus. Engr., vol. 80, no. 2, Feb. 1922, pp. 63–66, 103, 8 figs. Maintenance practice in reversing roll electric drives.

RUBBER

Machinery, Developments in. Modern Developments in Rubber Machinery, J. W. Howie. India-Rubber Jl., vol. 63, nos. 15 and 16, Apr. 15 and 22, 1922, pp. 17–25 and 13–18 and (discussion) 18–19, 40 figs. Apr. 15: Some recent improvements. Apr 22: Vulcanizing, type making, hose covering and special plant. Paper read before Instn. Rubber Industry, at Royal Soc. Arts.

Magnesium Carbonate Compounded with. Some Physical Properties of Rubber Compounded with Light Magnesium Carbonate, H. W. Greider. Jl. of Indus. & Eng. Chem., vol. 14, no. 5, May 1922, pp. 385–395, 22 figs. Data showing increase in tensile strength, hardness and resilient energy and probability of eliminating principal disadvantages by compounding filler in amorphous form.

Transparent. Rubber Glass—A New Product of Great Interest. India Rubber World, vol. 66, no. 2, May 1, 1922, pp. 538–539. Description of invention of Fordyce Jones, giving its advantages and limitations.

Vulcanization. Cold Vulcanization of Rubber, S. J. Peachey. Rubber Age, vol. 3, no. 2, Apr. 1922, pp. 61–66. Paper read before Inst. of Rubber Industry, London, on this method of determination with gases and advantages of same.

S

SAFETY ENGINEERING

Graphic Charts. Obtaining and Presenting Safety Statistics for the Busy Executive, A. M. Underhill. Safety Eng., vol. 43, nos 4 and 5, Apr. and May 1922, pp. 131–134, 199–204, 7 figs. Apr.: Methods of presenting statistics for determining what steps may be taken to prevent repetition of accidents in such form that they become intelligible to executives not familiar with work. May: Use of logarithmic paper for curve charts clearly shows accident increase or decrease.

SAND BLAST

Plants and Methods. Sand Blasting, E. L. Samson. Foundry Trade Jl., vol. 25, nos. 287 and 288, Feb. 16 and 23, 1922, pp. 115–118 and 143–144, 19 figs. High- versus low-pressure plants; abrasive power considerations; cost of sand blasting; sand-blast rooms, cabinets and tumbling barrels; sand-blast conveyors; dust collecting; etc. Paper read before Instn. British Foundrymen.

SAND, MOLDING

Dressing. The Dressing of Moulding Sand, Heinz Kalpers. Eng. Progress, vol. 3, no. 4, Apr. 1922, pp. 79–81, 5 figs. Notes on dressing of fresh sand, used sand and coal dross; drying furnaces for fresh sand; shaking sieves; sand-crushing mills with magnetic rollers; automatic dressing plants.

Preparation. Sand Offers Field for Improvement, Eugene W. Smith. Foundry, vol. 60, no. 7, Apr. 1, 1922, pp. 264–265. Factors besides physical characteristics and chemical analysis entering into preparation, classification and grading of sand used in preparation of molds into which metal is poured. From paper read before Chicago Foundrymen's club.

SCRAP

Deleading. Removing Lead from Scrap Metals (Das Entbleien von Altmetallen) Metall—Technik, vol. 48, no. 10, Mar. 4, 1922, pp. 92–93. Discusses wet and dry methods and describes operations.

Metal, Dezincification. Dezincing of Scrap Metal (Das Entzinken von Altmetallen, B. Haas. Zeit. für die gesamte Giessereipraxis, vol. 43, no. 12, Mar. 25, 1922, p. 154. Thermal and chemical processes used. Concludes that dezincification is more reliable and simpler than deleading.

SEAPLANES

Facilities on Atlantic Coast. Seaplane Facilities on the Atlantic Coast. Aviation, vol. 12, no. 18, May 1, 1922, pp. 506–507. Thirty-nine landing places for seaplanes listed in survey issued by Nat. Advisory Com.

SEMI-DIESEL ENGINES

Two-Cylinder Marine. New Two-Cylinder Semi-Diesel Marine Oil Engine. Oil Eng. & Finance, vol. 1, no. 2, Mar. 25, 1922, pp. 369–370, 1 fig. Design for small commercial vessels two-cycle hot-bulb developing 30 b.hp. at 425 r.p.m.

SHERARDIZING

Factors Influencing Process. Factors Influencing the Process of Sherardizing, Leon McCulloch. Elec. Jl., vol. 19, no. 4, Apr. 1922, pp. 156–160, 4 figs. Experiments in features not hitherto definitely known. .Growth of coating, effect of iron in zinc dust; effect of other metals in zinc dust; composition of coatings.

SMOKE ABATEMENT

Water Grates. Abatinga Smoke Nuisance, R. R. Hillman. Power Plant Eng., vol. 26, no. 9, May 1, 1922, pp. 463–465, 3 figs. Treatment of an unique case in department store in Buffalo where water grates also increased circulation of boiler water.

SOOT BLOWERS

Steam Consumption. Steam Used for Soot Blowing, Robert June. Power Plant Eng., vol. 26, no. 8, Apr. 15, 1922, pp. 414–415, 4 figs. Method of calculating steam consumption when time valve is open is known. See also Power House, vol. 15, no. Apr. 5, 1922, pp. 30–31, 4 figs.

SPECIFIC HEAT

Gas. The Specific Heats of Gas From the Point of View of Their Industrial Application (Sur les chaleurs spécifiques des gaz envisagées au point de vue de leur application aux problèmes industriels), Emilio Damour and D. Wolkowitsch. Révue de Métallurgie, vol. 19, no. 3, Mar. 1922, pp. 145–161, 2 figs. Reviews in detail literature on subject, and shows that there is no agreement between the various authorities.

SPRINGS

Impact, Absorption of. Graphic Representation of Absorption of Impact by Springs. Machy. (Lond.), vol. 20, no. 499, Apr. 20, 1922, pp. 93–94, 2 figs. Description of graphic method to determine energy absorbed under certain simple conditions.

Laminated. General Theory of Laminated Springs (Allgemeine Theorie der Blattfeder), Y. Tanaka. Zeit. für angewandte Mathematik u. Mechanik, vol. 2, no. 1, Feb. 1922, pp. 26–34, 6 figs. Deals with equilibrium of laminated springs under influence of an inclined load, taking into consideration friction and initial pressure between the plates, differing strength and shape of plates and curvature of spring.

STACKS

Venturi. New Stack Type, A. W. H. Griepe. Am. Gas Jl., vol. 116, no. 15, Apr. 15, 1922, pp. 343–346, 18 figs. New type similar in shape to a venturi tube combined with blower has advantage of flexibility of operation, and low cost of installation and maintenance.

STANDARDIZATION

Reducing Cost. Reducing the Cost of Standardization, W. O. Lichtner. Management Eng., vol. 2, no. 5, May 1922, pp. 275–280. Need and possibilities of handbook of times for performing manufacturing operations including charts and tables showing elementary operations analyzed to simplest items.

STAYBOLTS

Failure. Defective Staybolts Cause Locomotive Disaster, A. G. Pack. Boiler Maker, vol. 22, no. 4, Apr. 1922, pp. 97–99, 3 figs. Report of failure of Pennsylvania R. R. locomotive, submitted to Interstate Commerce Commission. Explosion partly due to heavy grooving of back head at mud ring.

STEAM

Generation, Distribution and Use. The Generation, Transmission and Use of Steam (Dampferzeugung, Dampfforteitung und Dampfverwendung), H. Lasser. Wärme (Zeit. für Dampfkessel u. Maschinenbetrieb), vol. 45, no. 1, Jan. 6, 1922, pp. 1–3. Notes on economic steam generation; steam distribution and conduction; and use of steam for generation of power and of steam for cooking and heating purposes.

High-Pressure. Higher Steam Pressures, Joseph Jares. Combustion, vol. 6, no. 5, May 1922, pp. 221–223, 1 fig. Consensus of opinion of most writers favors higher pressures and temperatures. Advantages. Letters from C. J. Stover, Sec'y of Magnesia Assoc. of Am., and W. S. Lockwood, of Johns-Manville, Inc.

The Properties of Steam under High Operating Pressures (Bemerkungen zu den Eigenschaften des Wasserdampfes bei hohen Betriebsdrücken), G. Eichelberg. Zeit. des Vereines deutscher Ingenieure, vol. 66, no. 12, Mar. 25, 1922, pp. 275–277, 6 figs. Differences in the values for heat of evaporation obtained by Schüle and Eichelberg. Possibility of indirect measurement of specific heat of saturated steam based on relation between exponent of the adiabatic curve, heat of evaporation and specific heat.

Metering of. The Metering of Steam, John L. Hodgson. Shipbldg. & Shipg. Rec., vol. 19, no. 15, Apr. 13, 1922, pp. 466–468, 5 figs. Steam meters developed by author and his firm, Geo. Kent, Ltd., during last twelve years.

Specific Heat of Superheated. The Specific Heat of Superheated Steam for Pressures of 20 to 30 Atmos. (Die spezifische Wärme des überhitzten Wasserdampfes für Drucke von 20 bis 30 at.), Osc. Knoblauch. Zeit. für technische Physik, vol. 3, no. 2, 1922, pp. 39–40. Results of tests carried out in conjunction with E. Raisch.

STEAM ENGINES

Heat Economy. Using the Heat of Piston Steam Engines to Best Advantage (Die Wärmeausnutzung der Kolbendampfmaschine), W. Schmidt and R. Wolf. Zeit. des Vereines deutscher Ingenieure, vol. 66, no. 14, Apr. 8, 1922, pp. 345–350, 4 figs. Discusses increase of pressure from 18 to 55 atmos., increase in expansion of steam, intermediate superheating, etc., on basis of latest experiments by W. Schmidt and R. Wolf.

Indicator Diagrams. Indicator Diagrams. Power, vol. 55, no. 15, Apr. 11, 1922, pp. 574–576, 28 figs. Contains diagrams from Corliss, uniflow and non-releasing four-valve engines.

Uniflow. Uniflow Blooming-Mill Engine. Eng. Progress, vol. 3, no. 4, Apr. 1922, pp. 69–71, 6 figs. Effect of inlet condensation; different principles of uniflow action. The Demag uniflow engine with two rows of slits. Comparisons with long-piston engine.

STEAM PIPES

High-Pressure. Safety in High-Pressure Piping of Steam Power Plants (Die Sicherheit beim Betrieb von Hochdruckrohrleitungen in Dampfkraftanlagen), H. Menk. Wärme, vol. 45, no. 4, Jan. 27, 1922, pp. 56–59, 11 figs. Discusses measures and devices employed for increasing safety in use of such pipes.

STEEL

Defective Points, X-Ray Examination. Fundamentals for Determination of Defective Points in Steel by Means of X-Rays (Grundlagen für die Feststellung von Fehlstellen in Stahl mittels Röntgenstrahlen), E. H. Schulz. Stahl u. Eisen, vol. 42, no. 13, Mar. 30, 1922, pp. 492–496, 19 figs. Describes apparatus for examination with X-rays, and results obtained; depth of irradiation; investigation of welding points.

Molybdenum. See MOLYBDENUM STEEL.

Structural. See STRUCTURAL STEEL.

X-Ray Examination. X-Ray Investigations of the Structure of Steel Ingots and Billets (Röntgenstruktur-Untersuchungen an Blöcken und Knüppeln), Fr. Heinrich. Stahl u. Eisen, vol. 42, no. 14, Apr. 6, 1922, pp. 540–542, 6 figs. Results of tests carried out according to the Laue process. X-ray photographs are presented and described. In a second article by R. Glocker, the technical application of process is described (pp. 542–543, 2 figs.) Discussion of both articles, pp. 543–545.

[See also IRON AND STEEL; METALS.]

STEEL, HEAT TREATMENT OF

Ball Bearings. Ball Bearing Steel and its Heat Treatment, Carl T. Hewitt. Forging & Heat Treating, vol. 8, no. 4, Apr. 1922, pp. 196–198, 4 figs. Use of steels of from 0.60 to 1.50 per cent chromium content to meet extreme service demands. Methods of annealing and of hardening.

Hardening in Tempering Furnace. The Hardening of Steel Parts in Tempering Furnace (Das Härten von Eisenteilen im Härteofen). Zeit. für die gesamte Giessereipraxis, vol. 43, nos. 10 and 11, Mar. 11 and 18, 1922, pp. 129–131 and 142–144. Notes on proper design of furnace and methods of hardening.

Problems. Heat Treatment Problems—II, Leslie Aitchison. Metal Industry (Lond.), vol. 20, no. 5, Feb. 3, 1922, pp. 113–115, 3 figs. Deals with problems of cooling.

Tests. Relation of Time for Heating Round Sections to Surface per Lb. of Steel Exposed, E. J. Janitzky. Forging & Heat Treating, vol. 8, no. 4, Apr. 1922, pp. 179–181, 2 figs. Discusses experiments carried on by M. E. Leeds, results having been presented in paper, "Some Neglected Phenomena in the Heat Treatment of Steel," before Am. Soc. for Testing Mtls. and published in A.S.T.M. Proc., vol. 15, 1915.

STEEL MANUFACTURE

Basset Process. Blast Furnace Eliminated from Steel Making. Indian Industries & Power, vol. 19, no. 7, Mar. 1922, pp. 235–236. Some unsubstantiated reports of process discovered by Basset for producing steel direct from ore. Being tried out in Sheffield.

STEEL WORKS

British. Famous British Works. Eng. Production, vol. 4, nos. 77 and 78, Mar. 23 and 30, 1922, pp. 266–268 and 290–292, 9 figs. Describes works of Arm-

Important Announcement

to Users of

Standardized Bearings in Quantity

The A. W. Cadman Manufacturing Company has completed arrangements to furnish its metals, BEARITE, lead-base, and ACORN BRAND, tin-base, in bearings finished to size by a new process.

The bearings may be either straight babbitt, bronze back, steel back, or aluminum back.

This process, in conjunction with the unique properties of Cadman Metals, offers the following advantages:

(1) Perfect adhesion between babbitt and supporting shell.
(2) Complete elimination of "piping" and blow-holes.
(3) Sixty per cent. greater rate of heat dispersion.
(4) Guaranteed freedom from breakage of either babbitt or shell, when such guarantee is desired.
(5) Guaranteed double life of bearing.
(6) Favorable cost as compared with production by any other method.

The attached coupon, together with blue prints and statement of quantity used, brings prices and a copy of the enlarged, and completely rewritten, Engineering Bulletin M1, which is now on the press.

(Clip the coupon or simply enclose your card in an envelope)

Master Makers of Fine Bearing Metals
Since 1860

Without charge or obligation please send me Engineering Bulletin M-1, samples and information regarding the use of Cadman Metals in:

Machinery:..

Name:.. Position:........................

Company Name:..

Address:..

strong, Whitworth & Co., Ltd., shipbuilders and manufacturers of locomotives, marine engines, brass and non-ferrous metals, steel products, pneumatic tools, etc. Mar. 23: The Openshaw works devoted chiefly to manufacture of steel, armor plate, machine tools, etc. Mar. 30: The North Street works, representing later extensions to Openshaw works, and including large steel departments.

Electric, Southern Pacific Shops. Electric Steel Plant at the Southern Pacific Shops, Larry J. Barton, Chem. & Met. Eng., vol. 26, no. 18, May 3, 1922, pp. 838–840, 2 figs. Six-ton Heroult furnace produces all steel castings for large western railway as a side line. For a year it produced rivet steel from miscellaneous scrap, and now is working on order for 1,000,000 tie plates.

Power Plant. Power Plant Designed for Steel Mill Conditions. Power, vol. 55, no. 15, Apr. 11, 1922, pp. 566–570, 7 figs. Describes Inland Steel Co.'s plant no. 2, Indiana Harbor. Boilers are equipped with underfeed and forced-draft chain-grate stokers. Coke breeze,coal and coke-oven and blast-furnace gas used as fuel. Combination of four feedwater heaters operated in parallel.

STREET RAILWAYS

Controlling Excavations in Roadbed. Controlling Excavations Through Right-of-Way, R. B. Genest. Elec. Ry. Jl., vol 59, no. 17, Apr. 29, 1922, pp. 703–707, 17 figs. Montreal, Que., system wherein railway sanctions digging operations affecting its track and is compensated for expense therewith.

France. Present State of the Tramway Industry (Etat actuel de l'Industrie des Tramways), Roger Vente. Révue Industrielle, vol. 52, no. 6, Apr. 1922, pp. 183–189, 13 figs. Describes present practice in Paris, construction of tracks, rails, rolling stock, first and second class cars.

France. Present Technical State of Tramways. Industrie des Tramways, vol. 15, no. 177–178/179–180, Sept.-Oct./Nov.-Dec. 1921, pp. 149–355 (contains figs.). A series of reports presented before 2nd General Technical Meeting of Tramways Association in France, on rail profiles, frogs and crossings, track laying, curve construction, standardization of rolling stock, safety and comfort, power transmission, electrification of local railroads, etc.

Track. Expediting Track Construction in Toronto. Elec. Ry. Jl., vol. 59, no. 13, Apr. 1, 1922, pp. 551–558, 31 figs. Describes work in connection with relaying of tracks; gives standards of Toronto Transportation Commission.

STRUCTURAL STEEL

Wheels from I Beams. Fabrication of First Structural Steel Wheel, W. R. Ward. Forging & Heat Treating, vol. 8, no. 4, Apr. 1922, pp. 184–188, 13 figs. Difficulties encountered and problems solved in early experimental stage of construction of "I"-beam structural steel wheel.

SPARK PLUGS

Weaknesses. Sparking Plugs. Automobile Engr., vol. 12, no. 162, Apr. 1922, pp. 105–106, 6 figs. Five points to be considered in designing.

STANDARDIZATION

Domestic and European Movements. Recent Domestic and European Standardization Movements. Automotive Industries, vol. 46, no. 17, Apr. 27, 1922, pp. 912–913. Chains, tires and rims, petroleum, varnish and lumber.

STOKERS

Correcting Troubles in. Draft, Joseph G. Worker. Combustion, vol. 6, no. 5, May 1922, pp. 232–234, 240, 4 figs. Main points from forthcoming book, Mechanical Stoker, by J. G. Worker and T. A. Peebles. Draft one of most important features in correcting stoker troubles.

Mechanical. The Principal Types of Mechanical Stokers. Power House, vol. 15, no. 8, Apr. 20, 1922, pp. 19–21, 6 figs. Discusses chain-grate, underfeed, and overfeed stokers. Choice of stokers.

Multiple Underfeed. A New Type of Multiple Underfeed Stoker, Robert June. Power House, vol. 15, no. 8, Apr. 20, 1922, pp. 35–37, 7 figs. Many advantages described and curves of both calculated and actual performance given.

Sprinkler. Sprinkler Stokers in a Mill Power Plant. Power House, vol. 15, no. 8, Apr. 20, 1922, pp. 24–25, 2 figs. Small type requiring practically no special brick work; readily applied to any style boiler without structural alterations.

SUBWAYS

New York. Subways for City Transportation with Important New York Details, Robert Ridgway. Elec. Ry. & Tramway Jl., vol. 46, no. 1125, Apr. 7, 1922, pp. 161–164, 7 figs. Review of development of system and comparison with other forms of transportation.

T

TERMINALS, RAILWAY

London & South Western. Royal Opening of Waterloo Station, London & South Western Railway. Ry. Gaz., vol. 36, no. 12, Mar. 24, 1922, pp. 519–527, 13 figs. Describes station as reconstructed, including platforms, road approaches, general offices, and traffic working details.

TESTING MACHINES

Metal, Resistance of. New Method of Testing Wear in Metals (Nouvelle méthode d'essai des métaux a l'usure), L. Jannin. Révue de Métallurgie, vol. 19, no. 2, Feb. 1922, pp. 109–116, 11 figs. Describes machine for testing resistance of axle and bearing metals to wear. Pages 117–119, article by Leon Guillet on some friction tests carried out with the Jannin wear-testing machine.

Modulus of Elasticity. A New Testing Machine Giving the Elastic Limit and the Modulus of Elasticity (Nouvelle machine de traction donnant la limite élastique et le module d'élasticité), R. Guillery. Révue de Métallurgie, vol. 19, no. 2, Feb. 1922, pp. 101–108, 7 figs. Describes apparatus and its operation.

TESTS AND TESTING

Turbines. Equipment for Testing Turbines and Generators, C. O. Schooley. Elec. Jl., vol. 19, no. 4, Apr. 1922, pp. 163–166, 4 figs. Description of what is said to be model test floor for both steam and electrical equipment at S. Phila. plant of Westinghouse Elec. & Mfg. Co.

TEXTILE INDUSTRY

Lime, Use of. Use of Lime in Textile Industry. Cement, Mill & Quarry, vol. 20, no. 8, Apr. 20, 1922, pp. 45–47. Bleaching or "chemicking" process; boiling-out process with lime; dying; Kier liming; Renewed interest shown by textile industry.

TEXTILE MILLS

Power Plant. Economics of the Power Plant, Leo Loeb. Textile World, vol. 61, no. 18, May 6, 1922, pp. 193, 197 and 199, 3 figs. Analysis of problems. Address delivered at Symposium on Textile Manufacture and Economics held in Philadelphia.

Steam-Turbine Mechanical Drive. A Steam-turbine Mechanical Drive for Textile Mills. Mech. World, vol. 71, no. 1843, Apr. 28, 1922, pp. 307–309, 4 figs. Description of steam-turbine type of drive made possible by perfection of reduction-gears.

TIDAL POWER

Experimental Station. Project of an Experimental Tidal Power Station (Idées générales et pratiques pour l'établissement d'un avant-projet de station marémotrice avec usine régulatrice), M. Bare. Annales des Ponts et Chaussées, vol. 6, Nov.-Dec. 1921, pp. 252–289, 15 figs. Discusses proposed station at Aber-Wrac'h, near Brest; design and calculation of works, power control, etc.

TIME STUDY

Motion Study and. Time and Motion Study—VI, Eric Farmer. Eng. & Indus. Management, vol. 7, no. 12, Apr. 20, 1922, pp. 361–365, 7 figs. Experiments in bottling sweets and covering and packing chocolates. (Concluded.)

TOOL STEEL

Selection and Heat Treatment. Selection and Heat Treatment of Tool Steel, S. C. Spaulding. Blast Furnace & Steel Plant, vol. 10, no. 4, Apr. 1922, pp. 224–227. Discusses the various factors to be considered in selection of proper steel for a tool.

TOOLS

Fine. Engineers' Fine Tools. Machy. (Lond.), vol. 20, no. 497, Apr. 6, 1922, pp. 1–7, 21 figs. Methods and equipment used in quantity production by C. A. Vandervell & Co., Ltd., including various types of calipers, V-blocks, and clamps.

Manufacture of Small. A Small Tools Factory. Eng. Production, vol. 4, no. 78, Mar. 30, 1922, pp. 307–311, 14 figs. Describes equipment in works of C. A. Vandervell & Co., Ltd.

TRANSPORTATION

Freight, Railway and Automobile. Railroads or Automobile Routes? (Jernbaner eller automobilruter?). Teknisk Ukeblad, vol. 69, no. 12, Mar. 24, 1922, pp. 114–115. Comparative cost of railroad and automobile door-to-door delivery for freight transportation.

Trolley Car and Automobile. What the Trolley Car Has to Learn from the Automobile, H. L. Andrews. Gen. Elec. Rev., vol. 25, no. 5, May 1922, pp. 280–284, 3 figs. Analysis of preference of public for automobile over trolley car and suggestions for reclaiming of patronage by latter.

TUBES

Automatic Seam Welding. Automatic Seam Welding and the Manufacture of Tubes, J. L. Anderson. Acetylene Jl., vol. 23, no 10, Apr. 1922, pp. 483–489, 13 figs. Describes process of manufacturing welded tubing which, it is claimed, makes possible production of thin-walled tubing at fraction of cost of seamless steel tubing.

V

VALVES

Engine, Setting. Setting Valves by Elliptical Diagram, Arthur O. Gates. Power Plant Eng., vol. 26, no. 8, Apr. 15, 1922, pp 410–413, 1 fig. New method employed on marine engine when time for shutdown was limited.

VENTILATION

Automatic. Recent Tests on Automatic Ventilators, A. J. Mack and C. J. Bradley. Heat. & Vent. Mag., vol. 19, no. 4, Apr. 1922, pp. 36–38, 1 fig. Results of tests at Eng. Experiment Station, Kan. State Agri. College.

Present-Day Practice. Where We Are At in Present-Day Ventilating Practice, Nelson S. Thomson. Heat & Vent. Mag. vol. 19, No. 4, Apr. 1922, pp. 27–32, 1 fig. Comments on conditions how sought through installation and operation of properly designed air-supply system.

W

WASTE

Industrial, Measuring. Measuring Waste in Industry, C. E. Knoeppel. Taylor Soc. Bul., vol. 7, no. 2, Apr. 1922, pp. 69–76 and (discussion) pp. 76–80. Examination of method employed by Committee on Elimination of Waste in Industry of Federated Am. Eng. Societies.

WASTE PREVENTION

Boiler Refuse. Boiler Refuse Yields Unburned Fuel, Thomas Fraser and H. F. Yancey. Coal Trade Jl., vol. 53, no. 18, May 3, 1922, pp. 400–401. Recovery by washing approximates 20 per cent of total weight of waste material treated. Prepared by U. S. Bur. Mines in coöperation with Univ. of Ill. and Ill. Geol. Surv.

WATER PIPES

Metal, Corrosion of. The Corrosion of Metal Water Pipes (Die Korrosion metallener Wasserleitungsröhren), Hugo Kühl. Gas- u. Wasserfach, vol. 65, no. 7, Feb. 18, 1922, pp. 99–102. Discusses corrosion of lead, copper, zinc, and iron pipe, its injurious effects, and preventive measures.

WATER POWER

Canada. Installed Water Wheel Capacity in Canada Totals 2,763,000 hp. Contact Rec., vol. 63, no. 16, Apr. 19, 1922, pp. 344–346. Résumé of water power resources of Dominion, brought up to date by Water Power Branch, Dept. of Interior, shows 300,000 hp. added during 1921.

Canadian Resources. Water Power Resources of Canada. Eng. World, vol. 20, no. 5, May 1922, pp. 284–285. Installed water wheel capacity now totals 2,763,000 hp and many further enterprises are in prospect.

Chemical Industry, Development. Water Power Development and Progress in the Chemical Industries (Le developpement de la houille blanche et le progres des industries chimiques), Georges Kimpflin. Vie Technique et Industrielle, vol. 3, no. 30, Mar. 1922, pp. 479–486, 18 figs. Discusses hydroelectric plant of Cie d'Electricite Industrielle, with a head of 95 m. water storage; pressure conduits; electric equipment; 120000-volt transmission; cyanamide, calcium, carbide, etc. manufacture.

WELDING

Autogenous. See AUTOGENOUS WELDING.

Non-Ferrous and Dissimilar Metals. Welding Non-Ferrous and Dissimilar Metals, Fred E. Rogers. Can. Machy., vol. 27, no. 10, Mar. 9, 1922, pp. 26–28, 2 figs. Welding of aluminum and aluminum containers; welding of copper; brass and bronze; nickel; monel metal; etc.

Motor-Generator Repairs. Welding Reduces Cost of Repairing Motor Generators. Elec. World, vol. 79, no. 18, May 6, 1922, pp. 885–886, 1 fig. Account of repairs at Bryant St. Sub-station of Market St. Rys. of San Francisco, by use of welding.

Oxy-Acetylene. See OXY-ACETYLENE WELDING.

Pipe Construction. Possibilities of the Art of Welding in Pipe Construction, Frederick K. Davis. Heat. & Vent. Mag., vol. 19, no. 4, Apr. 1922, pp. 33–36, 12 figs. Few of typical methods including autogenous or local fusion by which manufacture has been greatly simplified.

WIRE DRAWING

Process. Fascinating Romance of Wire Drawing, John Kimberly Mumford. Raw Material, vol. 5, no. 3, Apr. 1922, pp. 91–94, 4 figs. Discusses wire drawing methods of J. A. Roebling's Sons Co. and R. L. Stillson Co.

WOOD PRESERVATION

Theory. Theory on the Mechanism of Protection of Wood by Preservatives, Ernest Bateman. Wisconsin Engr., vol. 26, no. 5, Feb. 1922, pp. 79–84 and 98, 5 figs. Experimental work of obtaining a non-toxic or "barren" oil from coal-tar creosote; a mathematical treatment to point out existence of a solubility partition. Presented before Am. Wood-Preservers' Assn. (Concluded.)

Z

ZINC ALLOYS

Research. Research Work on Zinc and Zinc Alloys, Wallace Dent Williams. Can. Foundryman, vol. 13, no. 4, Apr. 1922, pp. 24–26, 9 figs. Influence of copper, aluminum and iron additions; influence of temperature upon defects of castings, etc.

ZINC

Extraction. New Methods for Extracting Zinc From Its Ores (Nuovi processi di estrazione dello zinco dai suoi minerali), Gaetano Castelli. Rassegna Mineraria Metallurgica e Chimica, vol. 56, no. 2, Feb. 28, 1922, pp. 21–24, 3 figures. Discusses new method using a reverberatory furnace and an improved bisulphite method, and gives diagrams of operations.

Material-Handling Equipment as Used in the Iron and Steel Industry

By F. L. LEACH,[1] JAMSHEDPUR, INDIA

This paper describes the handling machinery and apparatus used in the manufacture of steel. From the time that the ore leaves the mines until the steel goes through the last process at the mill it is moved about exclusively by different types of heavy machinery designed especially for the purpose. The author expresses the hope that through his description, weak points in present-day practice will show themselves and means of improvement be suggested.

THE iron and steel industry probably requires a greater diversity of material-handling equipment than any other type of manufacturing, because of the enormous bulk and weight to be handled. From the time the material leaves the mines until it is turned out of the mills as finished product it is constantly being moved by heavy conveying machinery of all descriptions. It is the intention of the author to describe this equipment with the idea of bringing out weak points in present-day practice, and possibly open the way to strengthen the weakest links in the conveying methods used.

As the principal object of this paper is to describe the machinery used about the industrial plant, just a brief description will be given of the handling methods before the material reaches the plant.

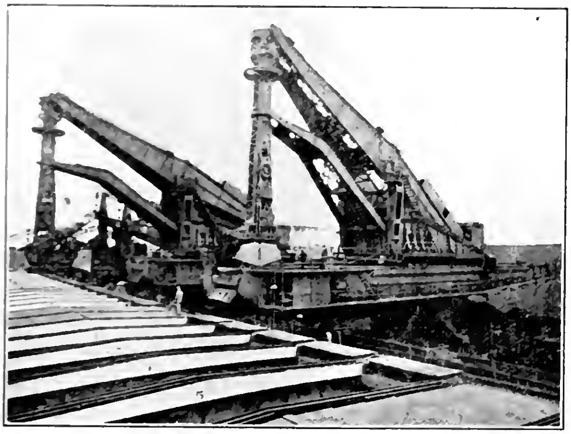

Fig. 1 Hulett Ore Unloader at Ashtabula Harbor

At the present time ore handling on the Great Lakes is carried on by a fleet of vessels unequaled anywhere in the world. Some of these vessels are capable of handling a cargo of 15,000 tons, and are over 600 ft. long. During the year 1916, 66,658,466 tons of ore were carried by the vessels from the upper Great Lakes to southeastern ports.

Vessels equipped for self-unloading have been developed for handling stone and ore. The hold in such cases is divided into bins, which deliver the material by gravity to a belt conveyor running lengthwise of the vessel; this conveyor delivers the material to an elevator which hoists it to another belt conveyor suspended in a horizontal position from the masts of the vessel and capable of being moved radially and vertically like the boom of a derrick. This belt conveyor delivers to the storage pile on the dock, and it is possible to distribute the material on the dock at any point or height desired within the scope of the boom conveyor.

Ore-unloading equipment has probably been developed to the highest point of efficiency at the ports on the Great Lakes. An example of this is Ashtabula harbor on Lake Erie, where there are eight Hulett ore unloaders having a capacity of 15 tons each. They have a record of unloading seven boats of a total capacity of 70,000 tons in 22 hours' actual time.. Four 17-ton-capacity machines of this type have unloaded a cargo of 13,000 tons in 3 hours and 25 minutes. Fig. 1 shows a view of these machines in operation.

These unloading machines remove the ore from the boat and dump it directly into railroad cars for shipment to inland plants, or they place it in a bin located at the rear of the machine where it may be picked up by a traveling ore bridge and placed in storage piles.

Ore shipped to inland plants in bottom-dumping cars may be unloaded directly into bins by gravity. However, the modern method is to use a traveling rotary car dumper as shown in Fig. 2, which can be spotted at any point in the length of the ore yard. The cars of ore are placed one at a time on the dumper, turned upside down and the ore dumped into a concrete pocket that extends the full length of the ore yard. An ore bridge similar to the one shown in Fig. 3 distributes the ore to the storage pile in the yard. Rotary car dumpers have been developed so that three men can unload about 20 cars per hour. Cars of 240,000 lb. capacity have been designed with a total dead weight of 78,800 lb., giving a ratio of revenue load to total weight of 75.4 per cent.

The traveling ore bridge is another valuable link in material-handling equipment and is used in many different ways in handling the ore at unloading docks. One of the largest bridges of this type ever built is 612 ft. long overall, and is used at the Western Pennsylvania Dock Company at Cleveland, Ohio. This bridge handles a 15-ton bucket and covers an ore storage of over a million tons.

Fig. 3 shows how these bridges may also be used to place the ore and limestone in bins, preparatory to sending them to the blast furnace. Several different types of bins are used, although the principle is the same in each. The ore is placed in the bin, either by the ore bridge or by gondola-type hopper cars, and it passes down through the bin by gravity as required, through a shut-off gate into a lorry car. From the bins an electrically driven weighing lorry car is used to convey ore, limestone and coke to the blast-furnace skip hoist.

Fig. 3 shows how material is conveyed from the stock yard and bins to the top of the blast furnace, dumped into the bell hopper by the skip car, and finally deposited inside by the well-known double bell system. Two of the products of the blast furnace are pig iron and slag, which are drawn off at the base in a molten state. Both iron and slag were formerly allowed to run from the furnace into sand molds and handled after cooling. Most plants today, however, run the molten iron and slag directly into ladles supported on special cars. In this way the iron is transported either to a pig-casting machine where it is cast into pigs, or to a mixer at the open-hearth plant where it is kept in the molten state, or further refined before it is placed in the bessemer converter for

Abstract of a paper presented at the Spring Meeting, Atlanta, Ga., May 8 to 11, 1922, of The American Society of Mechanical Engineers. All papers are subject to revision.

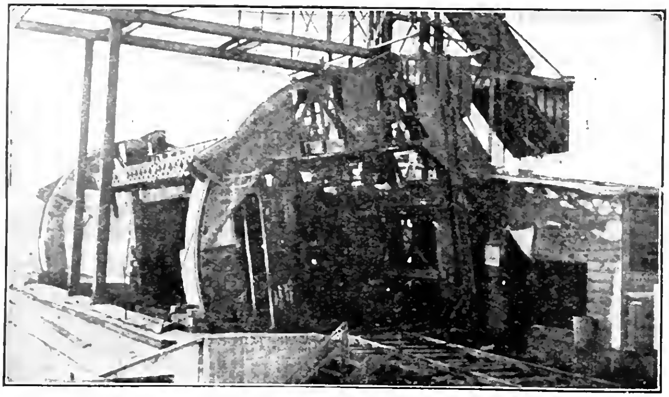

Fig. 2 View of Rotary Car Dumper

the duplex process. The molten pig iron may also be conveyed direct to the open-hearth furnace for the straight open-hearth process.

The slag is disposed of in various ways, since it has become of considerable commercial value in the last few years. After having been allowed to cool it is crushed to various sizes and then used in the place of crushed stone.

A new design of car known as the Pugh mixer-type hot-metal car, shown in Fig. 4, has recently been developed for handling hot metal from the blast furnace. This car, built in capacities ranging from 70 to 150 tons, is claimed to have many advantages over the ordinary type, chief among which are the heat-saving feature, which allows the hot metal to stand in the car for a period of 36 hours without "freezing." It is also a labor saver because, due to its large capacity, it requires fewer runners to distribute the metal from the furnace to the cars, thereby eliminating considerable scrap.

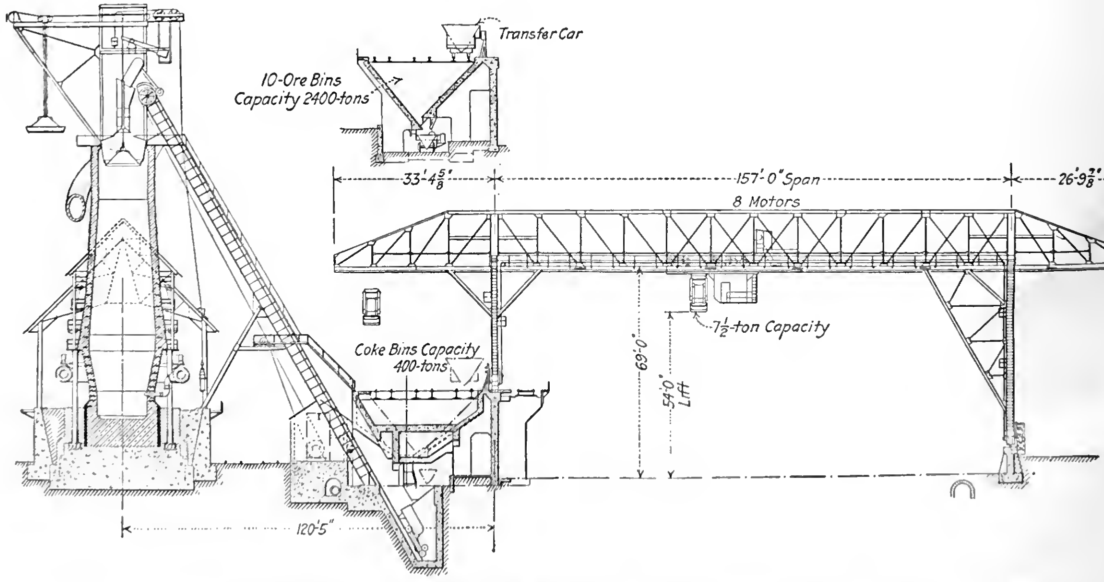

Fig. 3 Section Through Blast Furnace and Ore Yard Showing Relation of Ore Bridge, Bins and Furnace

Fig. 5 shows a view of a typical slag car for conveying the molten slag away from the blast furnace. It is dumped pneumatically.

The Duplex System for Making Steel

Fig. 6 shows the plan of a modern duplexing system for manufacturing steel. The machinery in this department of steel making must stand the most severe treatment of all, as the steel is handled at temperatures ranging as high as 2900 deg. fahr. It can therefore readily be understood how important it is to have such machinery and equipment designed as perfectly and as safely as possible.

The hot metal from the blast furnace is brought to the mixers by ladle cars. In Fig. 6 this car is shown in position before a 1300-ton capacity mixer into which the content is poured by lifting the ladle free from the car with the aid of a 100-ton ladle crane.

The hot metal is removed from the mixer as required by tipping it so that metal will run out of a spout opposite the receiving side. Another ladle supported on a ladle car is used to transfer the hot metal from the mixer to the bessemer converter. This ladle is tilted by a jib crane and the contents poured into the top of the converter already tilted to a receiving position.

The next step for the hot metal in the process of refinement is to convey it from the converter to the open-hearth furnace. This is done very much as was the previous operation, except that the hot metal is poured from the converter into another ladle mounted on a ladle car and is transferred by steam or electric locomotive to a point before the open-hearth furnace. Here, it is hoisted free of the car and poured into the furnace by means of an overhead crane. The track over which this car travels is indicated in Fig. 6 by the note "Hot Metal to Open-Hearth Furnaces."

Fig. 7 shows a 65-ton ladle car that may be used for this transferring operation.

Open-Hearth Furnaces

Scrap, ore and limestone are conveyed to the open-hearth furnace in cast-steel boxes called charging boxes, three or four of which are moved on a specially built car. The scrap is placed in the boxes by means of the overhead crane and a magnet. The ore and limestone are handled either by the crane and a grab bucket in cases where it is necessary to move them from storage piles to the boxes, or they are placed in the boxes direct from bins by means of chutes, when the plant is so provided. The cars are then hauled in trains to the charging floor of the open-hearth furnace building.

It occurs to the writer that the ore and limestone used in open-hearth practice could be handled more economically if they were either stored in bins under the approach trestle to the open-hearth

building and discharged by chutes into the charging-box cars, or if they were stored in bins under the open-hearth floor and removed by means of a grab bucket, or possibly by the application of mechanically operated proportioning devices used in conjunction with compartment bins discharging them to the charging floor of the open hearth.

In the methods now in vogue the train of loaded charging boxes is transferred from the storage yard to the open-hearth charging floor in front of the furnaces by means of an electric or steam locomotive. The material in the charging boxes is then dumped into the furnace by an electric charging machine. This machine lifts the charging box into the furnace where it dumps its contents by turning the box through a complete revolution. The operator of one of these machines sometimes takes a loaded box and uses it as a means of leveling the charge within the furnace much as a fireman would use a poker to level the coals in the firebed of his boiler.

The products of the open hearth are steel and slag. The steel is drawn off from the furnace and run into a ladle of a size consistent with the capacity of the furnace. In the Talbot system only half of the charge is drawn from the furnace at one time. After the ladle is filled it is transferred by an overhead crane to a position over the first mold of a train of ingot molds.

The slag which flows off at the time that the steel is tapped is run into a slag ladle mounted on a special car by which the ladle is carried to a suitable point for dumping. The position of this car is indicated on Fig. 6 by the letter (A). It is placed there to receive the slag during the tapping of the furnace and is hauled away afterward on the track indicated by the nete.

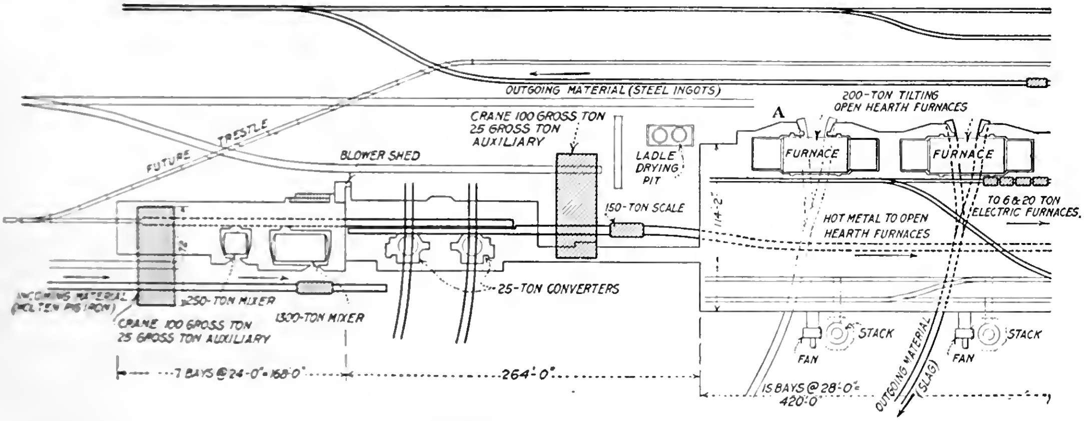

Fig. 6 General Plan of Duplex Plant

The molds in which the steel is cast are mounted on cars, usually three or four molds to the car. These cars are heavily constructed as they must withstand having molten metal splash on all parts of them or the dropping of an ingot from a height of several feet when the mold is being stripped from it.

The direction of travel of these ingot cars is indicated by arrow heads and notes as they travel from the open-hearth pit to the stripping yard.

Fig. 4 Pugh Mixer-Type Hot-Metal Car

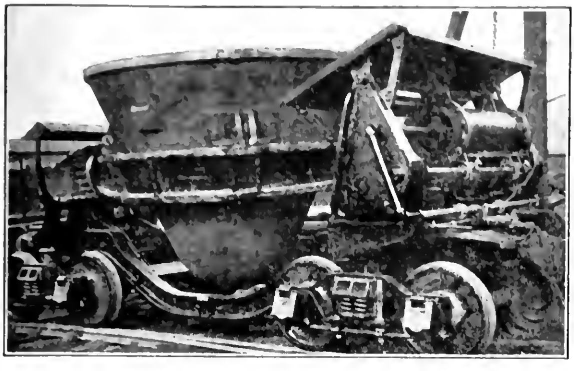

Fig. 5 Slag Car and Ladle

The stripping process simply means removing the molds from the cast ingots after the metal has hardened sufficiently. Fig. 8 shows an ingot stripper and indicates how the hooks of the stripper engage the ears of the mold, lifting it clear of the ingot car and leaving the ingot on the car. When the mold has been used for a long time it may become slightly pitted, causing the ingot to stick when it is being stripped from the mold. Under these circumstances it is necessary to drive the ram down into the opening at the top of the mold to force out the ingot.

The train of stripped ingots is now moved from the stripper yard to the soaking-pit furnaces, or to a suitable storage yard.

A Modern Rolling Mill

Fig. 9 shows a plan of a modern rolling mill in which nearly all the different types of material-handling machinery that have been developed to the present time for this industry are used.

This plant includes a 40-in. two-high reversing blooming mill, a 24-in. and 18-in. sheet-bar and billet mill, and a 28-in. rail and structural mill. Provision has been made for serving a 12-in. and 8-in. merchant mill with billets from this sheet-bar and billet mill. All mills are electrically driven. The different types of conveying machines are indicated by letters, in the order in which the material travels.

The blooming mill is served by six 4-hole soaking pits, in which the ingots are placed by an overhead electric tong crane. This crane handles the ingot on a principle similar to that of a pair of ice tongs. The operator's cage rides with and above the tongs, enabling him to place the ingots in the proper position in the pits.

The next step in moving the material is to serve the blooming mill with hot ingots from soaking pits. The soaking-pit crane delivers the ingot to a tilting buggy, places the ingot on roller table

(B), and it is directed properly for entering the rolls of the blooming mill by manipulator (C).

Fig. 10 shows a general view of the soaking-pit furnaces and the end of a roller table, to which an ingot is being delivered by the traveling tilting buggy. This buggy travels back and forth in front of the soaking pits, operated either by a remote-control switch which places the buggy at any desired position on the track, or motivated by an electric tractor—man-operated. In case of breakdown of the ingot tilting buggy the cranes can place the ingot directly on the table.

As previously stated, the manipulator is a machine used to place the ingot in the proper position for entering the rolls, and to turn or shift it for the next pass after passing back and forth through them. The modern manipulator is hydraulically operated. Its pushing arm has both a vertical and horizontal movement and is provided with a movable side guard on each side with tilting heads on one side for turning the section being rolled. This enables the operator to place the material at any desired position before the rolls.

Many mills are equipped with manipulators on both the entering and delivery sides of the mill, but when they are placed on the delivery side the tilting heads are omitted.

After the ingots have been reduced to blooms, slabs, or blanks by the blooming mill they are carried to the shear by another electrically driven roller table indicated in Fig. 9 as table (D). The shear cuts the blooms to required lengths, removing the fan tail end or crop end, as it is termed in the mill. This crop end is dropped down a chute at the shear to conveyor (E) which conveys it to a bloom-butt car located on the track next to the mill building. This conveyor is usually very heavily constructed, and, due to the irregular shapes handled, it is built so that the billets are pushed along on a smooth surface of plates by a traveling scraper conveyor which will handle any size or shape likely to be produced by the mill.

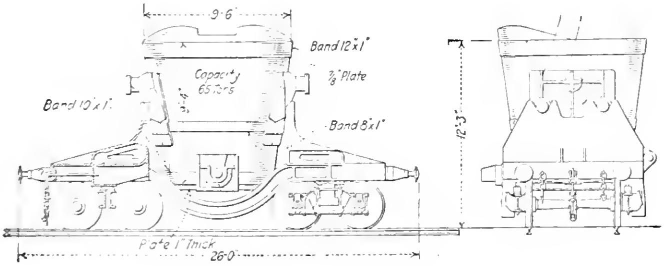

Fig. 7 65-Ton Transfer-Ladle Car

In some plants open-hearth charging boxes are placed on a charging car and the crop ends are loaded directly into the boxes by the crop-end conveyor. This is desirable where the distance between the blooming mill and the open-hearth is not great. If the distance is too far, too much money is tied up in charging boxes, due to the quantity necessary to provide for delays in transportation, etc.

The mill layout shown in Fig. 9 provides for distribution of blooms and blanks to the rail and structural mill by means of conveyor (F) and slabs and blooms to the hot hole or shipping yard by means of conveyors (G) and (H). It also provides for distribution of blooms and blanks to reheating furnaces or to rail mill by means of conveyor (F), table (J) and charging cranes (K) when reheating for rail mill, or for blooms and slabs direct to the sheet-bar and billet mill by table (L). Conveyor (F) shown in Fig. 11 is constructed with a surface of heavy tee rails, on which the billets are skidded along by rapidly traveling dogs. The dogs run on tracks between the rails and are attached to wire ropes running around an idler pulley at one end of the bed and a driving drum at the other end. This conveyor must handle the blooms rapidly as they are sometimes passed from the blooming mill direct to the rail and structural mill without being reheated.

Fig. 12 shows another type of these conveyors and also the grasshopper type of pusher, a machine used for removing material from a roller table to a conveyor placed at right angles to it.

The feature of this machine is the peculiar path which the ram describes in passing through one cycle of operation. The levers are arranged to cause the ram to travel in practically a horizontal straight line in the forward stroke, while on the return stroke it describes an arc in an upward direction, clearing material that may be traveling out from the shear.

When it is desired to deliver material to the hot hole it is removed from the shear table by means of the grasshopper pusher, to either conveyor (G), Fig. 11, in the case of slabs, or to conveyor (H) in case of blooms or blanks.

When slabs are delivered to conveyor (G) it transfers them to a slab piler which arranges them in piles of four or five. They are then removed by the overhead crane to be stacked in the hot-hole yard and allowed to cool.

The same procedure takes place when blooms are delivered to conveyor (H), except that the blooms are delivered to a cradle from which they are removed to the hot-hole yard for cooling and storage.

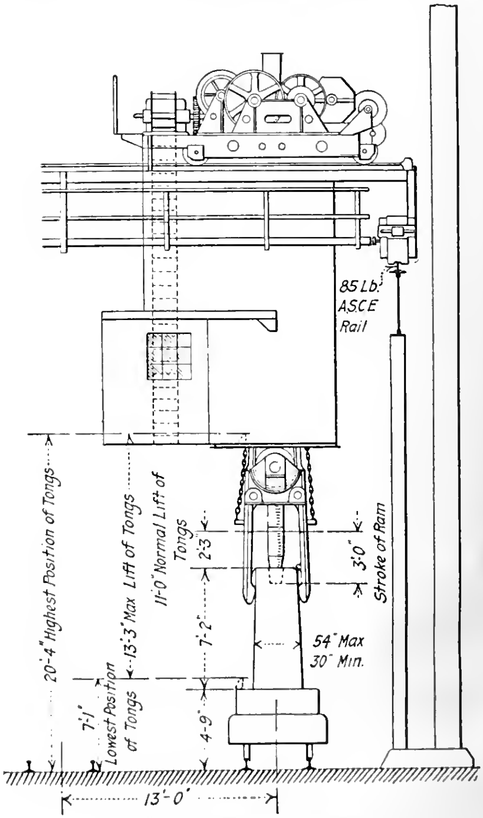

Fig. 8 200-Ton Ingot Stripper

The roller table indicated by reference (L), Fig. 9 is the ordinary type of electric-driven table.

Many types of machines have been developed to replace the old-style hand methods of replacing heavy billets, bars, etc., in the furnace for reheating, preparatory to rerolling. Reference (K), Fig. 9, indicates the location of two of these machines which travel on girders above the furnaces. They are designed so that the tongs may be placed in any position necessary to serve the furnaces on either side of the charging floor.

In the plant shown by Fig. 9 the charging crane (K) can pick up the material from the skids at the end of table (J) and place them in the furnace; store material at the end of the runway for future use; remove hot material from furnaces, and serve either the sheet-bar and billet mill or rail and structural mill. This arrangement allows many methods of operation between the different mills.

Sheet-Bar and Billet Mill

When it is desired to reduce the blooms to billets or flat bars they are conveyed direct from the blooming-mill shear to the 24-in.

mill by table (L) and rolled in the 24-in. mill without reheating. Some few sections, however, require reheating and the blooms for these are taken from table (L) by charging crane (K), placed in reheating furnaces, then returned to table (L), and to the 24-in. mill. After passing through the 24-in. mill they are delivered to the 18-in. mill by table (M), where the cross-sectional area of the bar is still further reduced. If it is not necessary to pass the bars through the 18-in. mill they are delivered to the stockyard or cars by means of a cooling-bed transfer conveyor (N), roller table (O) and transfer (P).

If it is necessary to pass the bars through the 18-in. mill they are conveyed to same by table (M). This table is designed with the axis of the rollers set at an angle of about 102 deg. with the center line of the table instead of 90 deg. for the purpose of throwing the bar off the table on to transfer conveyor (N). If it is desired to deliver the material to the 18-in. mill instead of placing it on transfer table (N) it is guided into a groove which is on the circumference of each roller, these grooves being in line on the table. Naturally this causes the material to follow a straight course to the 18-in. mill instead of being thrown off the table by the skewed arrangement of the rollers. After passing through the 18-in. mill the bars are cut to size by a rapidly operating shear, the knives of which move forward with the bar, cutting it as it rolls along. This type of shear is called a flying shear. The bars are then conveyed to cooling bed (Q), where they are allowed to cool, and transferred by the cooling-bed conveyor to a bar piler at the end of the conveyor. The bundles of steel bars or billets are then transferred to the billet storage yard, or to the merchant mill for further reduction to small shapes, or directly into cars for shipment by overhead crane (R).

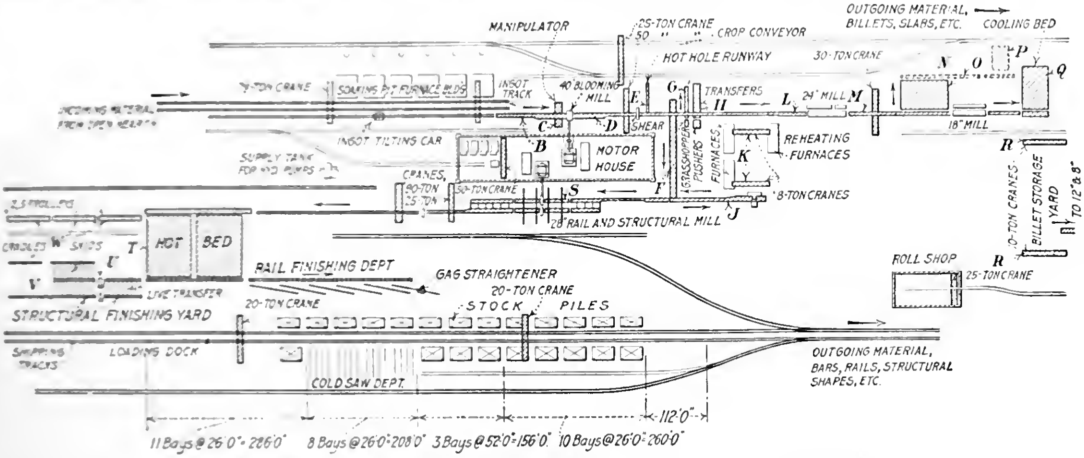

Fig. 9 General Plan of 40-in. Blooming Mill and Sheet-Bar and Billet Mill

28-inch Rail and Structural Mill

As previously mentioned, it is possible to deliver blooms from the blooming mill direct to the rail and structural mill by means of conveyor (F), thereby continuing the reduction of the bloom in the rail and structural mill without reheating. If it is desired to reheat the bloom, it is carried by means of conveyor (F) and roller table (J) to the end of table (J), where it is pushed on to the skid table, picked up by a charging machine (K), and charged into the reheating furnace. When properly heated it is returned to roller table (J) by charging machine (K).

Table (J) is designed with a double set of rollers so that blooms delivered to it may pass in either direction on both sides at once. The advantage of this can easily be understood; for example, conveyor (F) may be delivering material to the furnace on one side of the table and at the same time material may be transferred from the furnace to the rail and structural mill on the other side. This arrangement is shown on Fig. 11 by a light outline of the cross-conveyor at the delivery end of the conveyor.

If the bloom is to be rolled on the 28-in. mill it is carried to the mill by table (J) and a traveling tilting table (S). Two of these traveling tables are located on either side of the 28-in. mill and serve the purpose of catching the bloom as it travels back and forth through the mill. When the cross-sectional area of the bloom has been reduced to as small as is desired on the first stand, it is pushed over to the second stand by means of rope-propelled dogs which travel back and forth between the skid rails of a stationary transfer. The traveling tilting table (S) moves the material from pass to pass in either the top or bottom pass, as required. In event of either table breaking down, provision is made for removing the table beyond the face of the rolls where repairs can be made, and one table is used for both stands, which of course lessens production. When the roughing out is completed on the second stand of the 28-in. mill the material is passed to the finishing stand of the 28-in. mill. Here it is given one finishing pass of either a rail or structural shape and passed on to the saws by another power-driven roller table.

If the finished material is a rail it is generally cut into three pieces of standard length simultaneously by four drop hot saws, the two end saws being used to remove the crop ends of the rail. If a structural shape, it is cut by the sliding saw indicated to lengths desired. The material is then delivered to the cooling bed (T), on which it is drawn across by dogs attached to wire ropes or some other of the many methods of propulsion that have been designed for this purpose.

Rails are delivered in one direction to a rail-finishing department and structural shapes in the opposite direction to a department for finishing I-beams, channels, angles, etc.

When finishing structural shapes they must be straightened and the ends cut true. Fig. 9 shows a modern arrangement for transferring shapes from the cooling bed to the straightener (U) and thence to the shears, by means of transfers (V). When shapes have passed through this last stage of finishing they are removed from the shear cradle by means of overhead cranes (W) and placed in piles for storage or directly in railroad cars for shipment.

Rails pass through a similar process of straightening and end finishing and are also drilled. They are conveyed from the cooling bed on roller tables, and transferred to the different finishing machines on idler rollers supported on individual stands.

The writer is of the opinion that the methods of handling rails in the finishing department can be materially improved and more of the manual labor eliminated by plant arrangements different from those used at the present time. Not enough power-driven machinery is used in this work. This problem could be studied with beneficial results.

The foregoing description gives a general idea of the types of material-handling machinery used in a steel mill, but of course does not cover all the variations that would naturally be required in manufacturing different forms of steel. For example, there are several types of mills which have not been mentioned, all of which require material-handling equipment suited to the type of material handled.

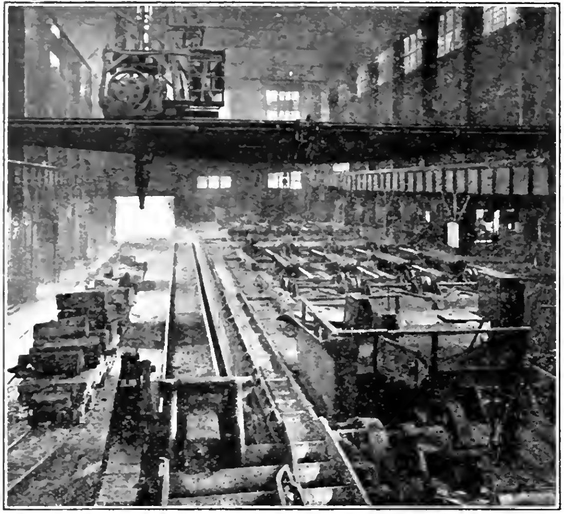

Fig. 10 General View of Soaking Pits, Ingot Tilter and Tong Crane

The mill for manufacturing steel plates requires lighter but broader tables, and toward the finishing end chain conveyors are used to handle the plates. At the shears an arrangement of castors set up on spindles is used, allowing the plate to be placed at any desired relation with the shear. This arrangement is known as a castor bed.

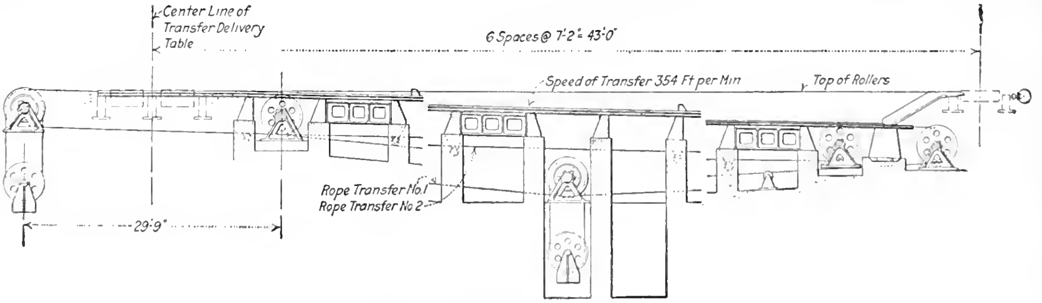

Fig. 11 145-ft. Bloom Transfer

The skelp and rod mill requires light tables and conveyors which will handle the rolled material rapidly, as the mills used for this work are small and run at a high rate of speed. They also require long cooling beds that will handle the material in such a manner that it is straightened while cooling. The Edwards escapement bed is a good example of this type, and is shown by Fig. 14. The rods are delivered to the top of the bed by a conveyor having a set of cone-shaped rolls. These throw the rod to the small end of the roll, which retards the speed of the rod and allows a set of fingers to pick it up and place it on the first of a series of spurs on an inclined bed. As each rod passes out from the mill it is picked up and placed on this inclined bed, and as each is dropped on the bed the preceding rods are dropped down one spur at a time until they reach the bottom. This intermittent dropping from one spur to the other straightens the rapidly cooling rod, so that when it reaches the bottom it is straight enough for ordinary purposes. The rod is then pushed out on to a roller table at the bottom of the cooling bed, and conveyed to the shear where it is reduced to the desired length. In some cases where the rods are small in diameter, for example $^1/_4$-in. and $^5/_{16}$-in., they are passed from the mill direct to coiling reels, where they are coiled into bundles and placed on a slow-moving coil conveyor. This allows the bundles to cool before being placed in storage piles or on cars for shipment.

Sheet and Tube Mills

Although material-handling equipment in sheet mills has improved considerably in the last few years, it is the opinion of the writer that there is greater chance for improvement in handling equipment in this type of mill than any other, as a vast amount of work is still done by hand.

Continuous furnaces for heating sheet bars have been developed to replace the old reverberatory hand-charged type. These furnaces are fed by a special pusher arrangement, which places the sheet bars in the furnace in piles. Before they are removed these piles must be scattered, which is done on a hearth at the outlet of the furnace, thereby allowing thorough heating, and facilitating the removal of the bars from the furnace to the mills for rolling. The bars are transferred to the mill by hand, except in the case of jobbing mills handling bars for making light plates, where a mechanical arrangement is used. It is the opinion of the writer that some such method could be used to advantage on most sheet mills, especially where long sheets are made requiring a maximum-sized sheet bar to begin with.

The mechanical doubler used for doubling the sheets in rolling to finer gages, is one recent improvement which eliminates the disagreeable task of doing this work by hand or by the old-style cylinder-operated clamping machine.

This point of steel manufacturing is sadly lacking in material-handling equipment, and is a fertile field for development. Material is moved by hand to and from furnaces, to and from shears, and through the finishing processes of sheets, to an extent which should be eliminated by roller tables, chain conveyors, or even overhead monorail trolleys, any one of which properly installed would lighten the load now placed on human shoulders.

It might be said that the tube mill is a continuation of the plate or skelp mill, where tubes are made by bending up and lap-welding the plate or drawing the smaller-sized skelp through a bell-shaped die to be butt-welded. Material-handling machinery for this type of work is well developed, and through the use of overhead cranes, conveyors, special pushers, etc., the manual handling of material is almost entirely avoided.

Forgings

Heavy forging is another branch of the steel industry that requires special handling machinery. Fig. 13 shows a manipulator

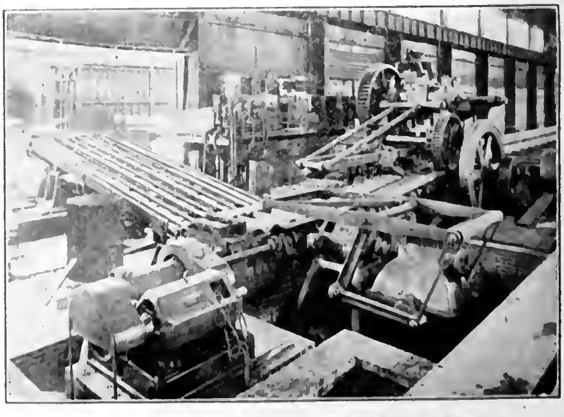

Fig. 12 Billet Conveyor and Grasshopper Pusher

which when controlled by a skillful operator can handle a 3-ton forging with as great dexterity as a blacksmith handles a horseshoe. Such a machine may also be used to feed material into rolling mills of different types. Primarily, it is operated by three motors. The first controls the vertical travel of the end of the peel, the second rotates it on its own axis and the third moves it laterally by turning the car body on the truck. A hand wheel controls the height of the rear or pivotal end of the ram so that it can be kept as nearly horizontal as possible. Two sets of springs are provided to give flexibility in both a vertical and horizontal direction and the tongs are operated with compressed air furnished by a compressor mounted on the frame. The whole machine is moved on its track by two motors on the truck.

Miscellaneous Equipment

Many types of conveyors are used in steel-plant auxiliary equipment, such as gas-producing plants, power plants, coal-pulverizing units, etc.

Among the most novel of these is one type of modern plant for pulverizing coal, in which the pulverized coal suspended in air is conveyed about the plant in pipes. The lump coal is delivered to this plant by gondola cars, dumped into a track hopper, passes to a crusher by means of a reciprocating feeder, and from the crusher is conveyed to an overhead storage bin by a gravity-discharge bucket conveyor. At the base of the storage bin is a belt conveyor which delivers the crushed coal to a drier. In some cases the coal is delivered from the drier to the pulverizers by an enclosed bucket elevator and in others by a chute, depending on the relation of the driers to the pulverizers. This is the point where the system of using air to convey the coal is employed. A blower is used to induce a current of air into the pulverizer, blowing the fine coal dust out of the top of the pulverizer through a pipe up into a cyclone collector. Here the coal dust is allowed to settle into a bin, the air being drawn out of the top of the collector by the same fan, which again passes it through the pulverizer to pick up more coal.

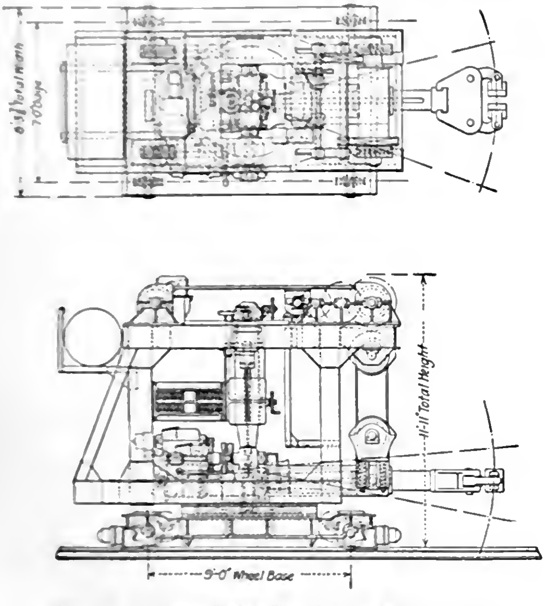

Fig. 13 Alliance Three-Ton Forging Manipulator

The pulverized coal is conveyed from the storage bin by means of screw conveyors to a heavily designed, powerful blower, which blows the coal through a circuitous system of piping to the points where it is to be burned, the surplus coal returning to collectors, which again allow it to settle into the storage bin. This system has been successfully installed in several large steel plants where the pulverized coal has been used for open-hearth furnaces, reheating furnaces and boilers.

The many types of conveyors, such as bucket elevators, scraper conveyors, etc., which are used about a gas-producing plant are too numerous to mention and too well known to require description.

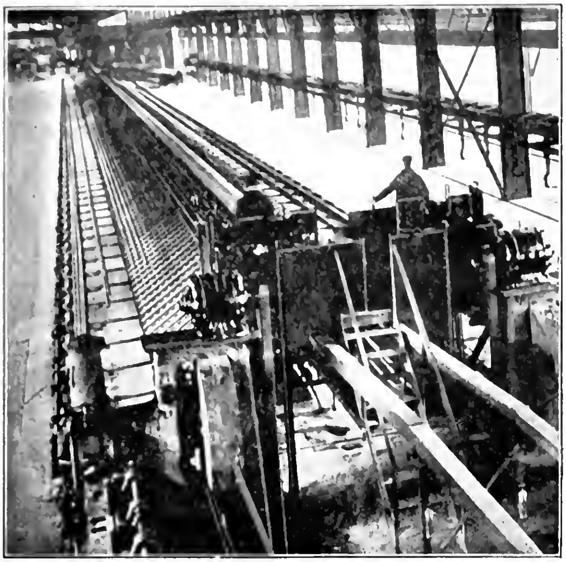

Fig. 14 Edwards Double-Escapement-Type Cooling Bed

Power

Nearly every known type of power has been adapted to material-handling machinery about a steel plant. Steam and hydraulic power have been used quite extensively, but are both being gradually replaced by electricity. Air under various pressures has also been adapted to many types of pneumatic machinery. Hydraulic pressure is used on heavy slow-moving machines, tilting open-hearth furnaces, ingot tilting pots, manipulators, shear-depressing and tilting tables, etc. Most of these types of machinery are now being handled by electrically driven cranks or racks.

General

To summarize the problem of material handling in the iron and steel industry, it is quite apparent that there are many gaps in handling material from the ore mines to the finished steel which can be improved, even with the present methods of manufacturing. Notably among these are the methods of conveying raw materials to the open-hearth furnace, and the many steps required from the blast furnace to the finished steel ingot. In other words, they include the rehandling of material several times to obtain the desired refinement of steel, which is especially important where most of the material is handled in a molten condition with its consequent high cost. It is the author's opinion that this refining process will change materially in the next few years through the medium of electricity, and as central power plants become more highly developed and more of our natural resources are put into use to obtain cheap electrical power, furnaces will be developed that will operate by a continuous process. They should be able to take the ore at one end of the furnaces, and with the addition of material at different points obtain the alloy desired at the pouring end, thereby eliminating the handling now required from one furnace to the other by miscellaneous containers, ladles, etc.

In reducing ingots to the finished steel product, improvements should be made which will increase the safety of working conditions and eliminate as much as possible by proper ventilation at the mills and well-ventilated operating pulpits located at a distance from hot work, the disagreeable conditions arising from heat. Machinery should also be developed, wherever possible, to eliminate the necessity of handling hot steel with tongs around bar mills, rod mills, sheet mills, etc.

There is without a doubt a vast field for research and improvement in this industry, as there is in all others, and it is for us, as engineers, to continue our endeavors and bring out these improvements.

Centrifugal Casting

A Résumé of the Development and a Discussion of the Design and Operating Problems of Centrifugal-Casting Processes and Their Field of Application

By LEON CAMMEN,[1] NEW YORK, N. Y.

In this paper the author describes the process of centrifugal casting of hollow metal objects. He first deals with the field of centrifugal casting and the history of the development of the art and then discusses the mechanics of the problem and describes the operation of the casting machine. Following this he takes up the thermal conditions in the mold and the field of application of hot-mold centrifugal casting, closing with a discussion of the manufacture of plates by the centrifugal-casting process.

THE centrifugal casting of metals is an old art, but it did not assume commercial importance until the last decade. Since then, however, while it has not attracted much public notice, its progress has been very rapid. It has already become an important factor in such work as the manufacture of paper-mill rolls and railroad car wheels. It is today the most vital problem before the makers of cast-iron pipe in the United States, and, with its recent developments, promises to revolutionize the two most profitable lines of the great steel industry, namely, tubular goods and plate manufacture. In the present paper it is intended to describe the process of centrifugal casting of hollow metal objects. The field of centrifugal casting is, however, far more extensive. The process has been successfully applied in the production of non-metallic tubes, such as concrete pipe (Hume process and others), in the production of solid castings by locating the molds around the rim of a spinning wheel, and also to a limited extent in the production of solid ingots by a largely similar process.

The field of application of centrifugal casting is far more extensive than is generally realized and the process is already being worked on a large scale. In the first place, centrifugal casting is a cheap method of producing goods of certain shapes, namely, those having a hollow interior symmetrical about an axis passing through the body of the casting, whether concentrically or eccentrically. The advantage of such methods lies in the fact that with proper equipment a very large number of units can be produced with comparatively little labor and without the use of cores, and that a greater homogeneity of metal is obtained than is possible with the ordinary method of casting. During the war several concerns employed this method, for example, for the production of piston rings for automobile engines, and even now establishments like the Ford Motor Company continue to use it for that purpose.

The Sandusky Foundry and Machine Company, Sandusky, Ohio, employs centrifugal casting to produce bronze paper-mill rolls and propeller sleeves, which would be much more expensive and probably less satisfactory if cast in a stationary mold. The Stokes Casting Co., Ltd., Mansfield, England, has used the same method for making cast-iron liners for aluminum cylinders of internal-combustion engines of such a small thickness and high grade of metal that they could not be duplicated by any other process except machining, and at a price only a small fraction of what a machined tube would have cost.

In the field of cast-iron pipe centrifugal casting is in a fair way to displace sand-molded pipe entirely. The method of centrifugal casting of cast-iron pipe has been primarily developed by a Brazilian engineer, Dimitri Sensaud DeLavaud, and has been extensively employed in England, Canada and Japan. Some months ago the United States Cast Iron Pipe and Foundry Co., of Burlington, N. J., one of the largest manufacturers of cast-iron pipe in the world, acquired the DeLavaud patents for America and are going into the manufacture of centrifugally cast cast-iron pipe on a large scale. It is stated that they can make 600 lengths a day with 25 men and the centrifugal process, as against 400 lengths with 80 men by sand molding, in addition to which centrifugally cast pipe is roughly 15 per cent stronger than sand-cast.

Another development in centrifugal casting in this country which has already become of commercial importance is the manufacture of railroad wheels. The idea itself is not new and there are English patents describing it dating back to the early sixties. As cast centrifugally by the American Steel Foundries, the wheel has a manganese-steel rim and a soft-steel hub and spokes, the depth of penetration of manganese in the rim being regulated at will.

Of late, centrifugal casting has acquired a further importance in the development of a method by which tubes and hollow billets may be successfully cast of such metals as monel metal and alloy steels, which can neither be cast into thin-walled tubes nor pierced by the ordinary methods. Recent developments in the art are such as to open really great possibilities for the future, a matter which will be discussed in a later part of this paper.

The art of centrifugal casting of hollow metal objects is quite old and has been practiced on a commercial scale since the beginning of the last century. The earliest English patent (Eckert) dates as far back as 1809, and the earliest American patent to Lovegrove was issued in 1848. At about the same time Andrew Shanks, in London, England, began to make cast-iron pipe 12 ft. long and 3 in. in diameter by pouring molten metal into a spinning wrought-iron mold. His process was described in America in the *Scientific American* of December 1, 1849, and it is of interest to note that in its basic features of design the Shanks machine does not differ in any way from the great majority of machines working with a cold mold at the present day.

Attempts were made at an early date to apply centrifugal casting to ingot making with the view to improving the quality of the metal and, for example, M. Tresca, in a paper before the Institution of Mechanical Engineers,[1] stated that the most remarkable instance he had met with of freedom from air bubbles was in the case of a bessemer rail manufactured at the Imphy Iron Works near Nevers in the Department of Niévre, France; and he had ascertained that the method adopted at this plant was to pour the molten metal into a revolving vessel driven at a considerable speed so as to clear the steel of air by rapid rotation. This method proved very effective in practice in freeing the steel from the minute air bubbles which it contained on leaving the converting vessel or the melting pot.

A survey of the literature and of the numerous patents issued on centrifugal casting in this country and in Europe would indicate that practically all the essential features were covered by patents issued prior to the beginning of the twentieth century, with the exception, however, of those dealing with the temperature control of the metal, which is a new feature. It would appear, therefore, that with the exception of minor details and one or two features in special casting processes, there is no reason why any good engineer cannot design and operate a successful casting machine with a non-heated or non-cooled mold without running into legal complications. At the same time, it might be well to realize that the very fact that the basic features of the general process are already free makes those who have developed some of the few minor features particularly anxious to protect their patent rights in them. Because of this a general familiarity with the patent situation is desirable to avoid involuntary infringement by using some minor detail that has been covered by a patent.

Mechanics of Centrifugal Casting

In the first place, a clear distinction should be made between casting about the horizontal and about the vertical axis and also the intermediate case of an inclined axis. In casting about a horizontal axis the metal is distributed symmetrically about the axis of rotation, and if the axis of rotation coincides with the axis of the spinning unit, a tube of uniform thickness is produced for

Abridgment of a paper presented at the Spring Meeting, Atlanta, Ga., May 8 to 11, 1922, of THE AMERICAN SOCIETY OF MECHANICAL ENGINEERS. All papers are subject to revision.

[1] Proc. Inst. M. E., 1867, pp. 149–150.

the entire length of the mold. If a vertical axis is used it is obvious that the external wall of the casting follows the shape of the mold, while the interior of the casting forms a paraboloid of revolution. In casting with an inclined axis the same general principles apply, with the further complication that the elements of the inside paraboloid of revolution are also affected by the angle of inclination of the axis to the true horizontal.

The usual way of casting is by introducing molten metal into the spinning mold. Where the chilling of the metal is extremely rapid, as, for example, in casting cast-iron pipe against a water-cooled chilled mold, it is imperative to use a movable spout, the latter sliding at a certain predetermined rate so that by the time the nozzle discharging the metal comes out of the mold the entire pipe is completed. This is the process employed by DeLavaud. Other manufacturers working with the cold mold have attempted to secure the same results by what is known as a trough spout, which is really a trough into which the entire metal of the casting is poured at a rapid rate. The trough is then tipped and discharges the metal suddenly, the metal falling on to the walls of the mold at such a rapid rate that a pipe forms before the metal has had time to chill. Hitherto this process has met with only indifferent success.

A better result has been achieved on comparatively short castings, however, by the use of a ledge spout, the spout ending in a flat ledge along which the metal can flow the entire length of the casting. Finally, where a hot mold is used an ordinary short spout is employed, the metal distributing itself throughout the mold longitudinally under one of the components of centrifugal pressure or pressure produced by centrifugal action. This arrangement cannot be used with a cold mold.

In centrifugal casting the distinction should be clearly made between jobbing work and mass production. For the former, clay molds in iron cases have been used practically exclusively, as it would not pay to make a permanent mold for only a few castings. When it comes, however, to production on a tonnage basis, such as tubing or pipe, a permanent mold is practically the only feasible way. Crucible graphite or zirconium tubes have been successfully used for castings not in excess of 3 ft. in length, but when it comes to longer ones, metal molds are to be preferred. Fairly successful results have been obtained with chrome-nickel alloys, though it is not expected that this will be the material finally adopted, as enough work has been done already on the production of cast tungsten to make it certain that a mold of this still rather mysterious material will be available within a comparatively short time.

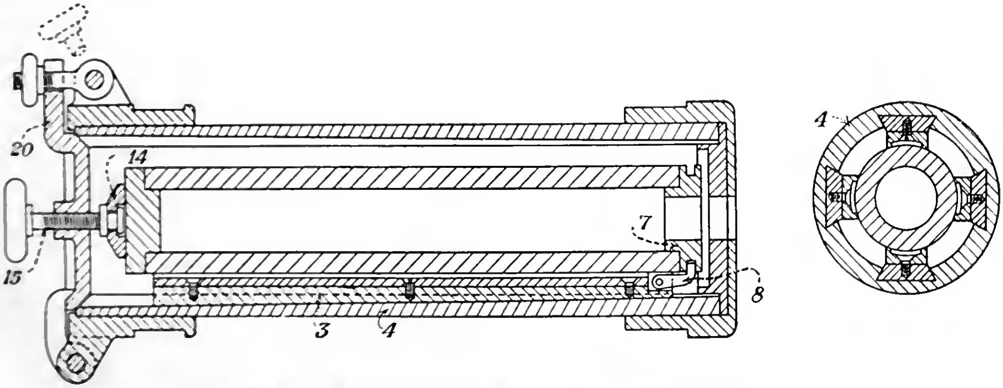

Fig. 2 Spinning Machine for Use With Removable Molds, Heavy Type

There are several ways of supporting the mold in the spinning bench, depending on whether the mold is a permanent fixture or removable and also on its size. Where the mold is a permanent fixture—as it is today wherever a cold mold is used, any kind of bearings, provided they are substantial enough, may be used. With removable molds the conditions are somewhat different, especially where the mold is heated to a high temperature. Where extremely hot molds have to be used, the arrangement must be such that the stresses on the mold can be reduced to a minimum, and that the mold can be rapidly and easily inserted into the machine and extracted therefrom. The matter of stresses is of very great importance in view of the fact that, especially in large machines, the bursting stresses due to the action of centrifugal force are of such magnitude as to require the most serious consideration.

The spinning bench for removable molds such as shown in Fig. 1 works on a comparatively simple principle, the mold being held in a barrel rotating on rollers, on which the pressure is adjusted by the wheel and screw shown at the top of the A-frame. This figure does not show the method of supporting the mold, and moreover, except for the very small sizes, three rollers are not sufficient.

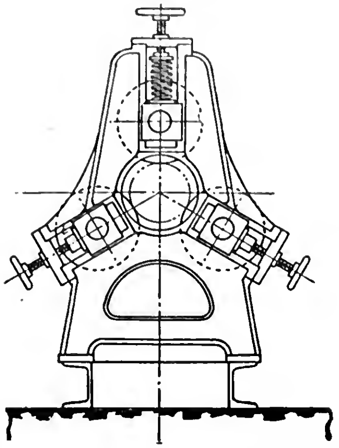

Fig. 1 Spinning Bench for Removable Molds (Suitable Only for Short and Light Molds)

The barrel construction shown in Fig. 2 is far more suitable for use with hot molds. Here the barrel consists of a steel shell, 4, which may be an extra heavy steel pipe, but in sizes above 12 in. has to be made as a special casting. At four to six places symmetrically spaced along the inner circumference of the shell, steel strips tapered at 39 and 40, Fig. 3, and with faces machined to the same radius as that of the internal surface of the shell, are screwed on or riveted on. The strips are provided with truncated slots as shown in the figure, and in these slots move the keys or gibs 51, the cross-section of which is shown by 37 and 36, which indicates that the face 36–37 is of the same width from one end of the gib to the other but the height of the trunk varies.

It is obvious that as long as the four gibs move through the same distance longitudinally in their tapered beds the faces of the gibs will remain parallel to each other, but the enclosed cylinder tangent to those faces will vary in diameter with the position of the gibs.

The operation of the machine is therefore as follows: The head 20 is opened and the gibs pulled out a little way until the tangent

cylinder is, say, a quarter of an inch larger than the external size of the mold. The mold is then inserted, preferably without touching the gibs, until it comes to bear against the abutment ring 7, to which all the gibs are attached (for example, by hooks 8). As the mold presses against the abutment the latter recedes and carries with it the gibs, which by moving in their tapered beds gradually close in until they grip the mold; and they may be made to grip it as hard as desired simply by exerting sufficient pressure on the abutment 7, which may be done by means of the block 14 and the screw 15.

The great advantage of this construction lies in the facts that, first, the mold automatically finds its own center, and, second, that it is supported all along its length, a matter of great importance when we come to deal with the bursting stresses in the mold. Whether a solid or a split mold should be used is a matter determined primarily by the shrinkage conditions of the metal of the castings and the metal of the molds. Where these are such that the casting comes out of the mold easily, that is, where it contracts quicker than the mold, a solid mold may be used, but where the shrinkage conditions do not guarantee easy extraction of the casting, or where they are non-uniform, the use of a split mold has been found advisable. Such molds are usually split longitudinally and the question of the best method for holding the two parts together is far less simple than it appears at first sight. There are numerous patents showing the two split parts of the mold held together by bolts. In actual construction, however, the use of bolts for this purpose is entirely unsuitable, for it can be shown that either bolts of prohibitive size would have to be used or the operation of a split mold held together by bolts would be extremely dangerous.

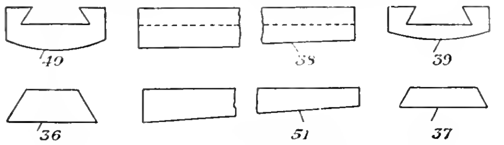

Fig. 3 Gibs and Beds of the Spinning Machine Shown in Fig. 2

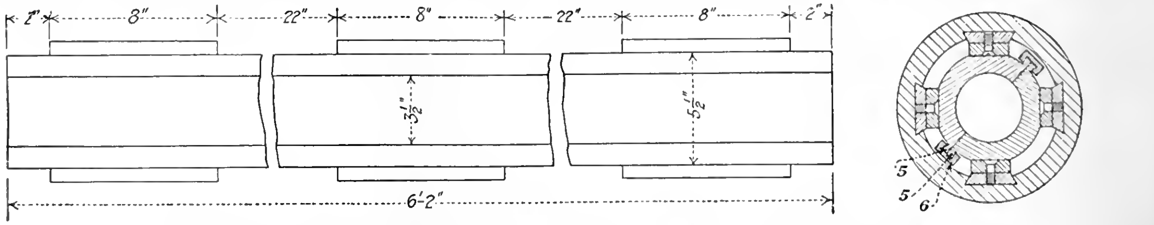

Fig. 4 Variation of Fig. 2, With Split Mold Held Together by Tapers and Dovetails

To meet this condition the mold shown in Fig. 4 has been developed. This mold has side lugs machined in such a manner that when the two parts are put together a tapered structure, such as 6, is obtained, and dovetail pieces 5 are provided to engage with the taper 6. It is obvious that when the dovetail piece 5 is driven hard over the lug taper 6, it will hold it tight. Furthermore, both the lugs and the dovetails can be made within reason practically as heavy as desired, so that a good factor of safety can be provided to take care of bursting stresses in the mold. To close or open the mold it is only necessary to apply pressure to the dovetail piece or give a light blow, and by means of a simple jig the blow or pressure can be applied to all the dovetail pieces on the mold at once.

It is obvious, however, that the presence of the lugs makes the machining of the mold to a true cylinder expensive, if not impossible. Because of this, instead of machining the mold to a cylinder, a number, such as four, of flat faces are planed on the mold, the location of the faces being such that they will be distributed symmetrically around the longitudinal axis of the mold and that they will be tangent to a circle described with the point on the axis of the mold as a center. Such an arrangement is comparatively easy to carry out and it gives an excellent support for the mold, besides providing a structure with good dynamic-balance properties.

As regards the foundations and bearings for centrifugal-casting machines no special design need be described here, but it should be most clearly and strongly emphasized that both the bearings and the foundations should be of very generous proportions and most substantial design. The machine in centrifugal casting is subject to quite violent strains and unless it is properly built it is apt to get into vibrations which sooner or later may have a dangerous effect.

Up to about two years ago very little work, as far as the author knows, had been done successfully on the problem of casting centrifugally comparatively thin sections, say, under $^3/_8$ in., in such metals as steels or monel metal and in lengths of over 3 ft. On the other hand, large castings in brass, bronze, cast iron and even steel have been made with considerable success. The reason for this lies in the failure to understand the thermal conditions in the mold and the process underlying the freezing of the metal.

There is a basic difference between casting in a stationary mold and in a spinning mold. In making castings in the former, whether it be a simple ingot or a complicated casting from a pattern, the foundryman has means to provide for the escape of gas from the metal and for taking care of the cavities produced by contraction in cooling. In a casting from a pattern, sink heads are provided, while in an ingot casting the top of the ingot acts as a sink head, in addition to which special methods such as "dozzling" may be used to keep the top of the ingot hot as long as possible, and increase the efficiency of the ingot top in performing the functions of the sink head in molds. In both cases the foundryman is prepared to discard as defective a certain part of the casting (the ingot head, risers, sink heads) and his skill lies partly in reducing the quantity of discard as far as possible and especially in directing the process so as to restrict the presence of defective metal to the parts which he is prepared to discard.

In centrifugal casting, however, there is no riser or anything corresponding to the ingot top, and the cooling proceeds essentially at a uniform rate all along the length of the tubular shape. It is obvious, especially in tubes of small diameter and considerable length, such as 6 in. outside diameter and 16 ft. long, that the loss of heat inward must be extremely small, because the entire inner air cylinder is surrounded by metal at approximately the same temperature. Heat is therefore lost mainly outward to the mold and through it to the air. As a result of this, the part of the casting in immediate contact with the mold chills first. The problems with which the "centrifugal" foundryman has to deal are essentially the same as those which confront the man pouring into stationary molds, and these are, first, to get rid of the occluded gases, and, second, to take care of contraction cavities. As regards occluded gases and slags, it would appear at first sight, especially to those familiar with such centrifugal processes as cream separation, that they would be eliminated automatically; pure metal, being heavier than either slag or metal containing gases, should be thrown to the outside, against the wall of the mold, while all impurities should go to the inner wall. This does actually happen, provided one condition is satisfied, and that is that sufficient time is available; and it should be remembered in this connection that this separation takes place at a fairly slow rate because of the great viscosity of molten steel.

The second problem is that of cavities formed in the casting as a result of contraction in cooling. As stated above, the part of the casting in immediate contact with the mold chills first. In doing so it contracts, and if left to itself might easily form contraction cavities and thin spots. If, however, the rest of the metal is still in a liquid state, it is projected, with a pressure at the rate

of, say, 100 lb. per lb. of metal, against the chilled layer, and fills all possible cavities with an efficiency many times greater than can be obtained with sink heads in stationary casting. (To obtain the same results in a stationary mold, it would have been necessary to put into the sink head 99 lb. of metal for every pound of metal in the actual casting, a propositon that is not likely to appeal to a sane foundryman.) This again presupposes, however, that the cooling proceeds at a fairly slow rate, and enough time is available for each succeeding layer to take care of chill conditions in the preceding layer. In cold-mold centrifugal casting, which means with a mold warmed only enough to take off the chill, say, 300 to 400 deg. fahr., temperature conditions do not favor slow cooling, which is one of the reasons of the many past failures to produce thin-walled steel tubing by centrifugal casting. On the other hand, very excellent steel tubes (both plain carbon and nickel alloy) have been produced with diameters ranging from 10 in. up and wall thicknesses up to $3^1/_2$ in. In the latter case there is so much metal in comparison with the area in contact with the mold that enough time is available to produce a good segregation of impurities inward before the inner wall freezes.

It would appear, therefore, that the secret of producing centrifugally thin metal castings (under $^1/_2$ in.) lies in establishing conditions under which the cooling of the molten metal will proceed at a fairly slow rate. This applies, of course, only to such metals as steels and monel metal, but not to bronze, which is governed by different conditions. In the Cammen process this has been accomplished by preheating the mold to a temperature close to the melting point of the metal itself, which may vary from, say, 1600 to 2000 deg. fahr. for steel and monel-metal castings. Under these conditions a $^3/_{16}$-in. wall takes about 45 to 60 sec. to harden completely, which is sufficient to produce clean metal. Casting in such extremely hot molds is a rather novel procedure and at first one might anticipate trouble due to oxidation and warping of the molds and the difficulty of handling large molds conveniently. As a matter of fact, however, with proper equipment it offers comparatively few difficulties. The question of oxidation of molds is taken care of by using proper alloys, such as alloys of a nickel-chrome base or cast tungsten (the latter, however, not yet being used on a commercial scale). The question of warping is partly taken care of by the same use of proper alloys, but mainly by the use of extremely substantial molds and proper facilities for handling them between the casting machine, the transfer table and the furnace. In all this handling, the molds have to be properly supported throughout the entire length, either by carrying them on a very heavy "horn" extending from one end of the mold to the other, or in a cradle supporting the mold throughout its length.

The method of operation is as follows: The mold with its casting inside, both at a temperature well above white heat, are rapidly pulled out from the casting machine and carried over to what is known as a transfer table, where the casting is pushed out of the mold by a hydraulic plunger. While the casting is going to the proper rolls or benches, the mold itself is coated inside by a protective layer and carried over to a reheating furnace. The furnaces used in this connection do not differ essentially from the billet-heating furnaces in tube mills. The mold coating is intended to protect the metal of the mold from coming into direct contact with the molten metal of the casting and need not be more than, say, $^1/_{64}$ to $^1/_{32}$ in. thick. It consists of some refractory material like alumina, zirconia, kaolin, electrically calcined magnesia, or the like. Either pitch with some addition of solvent naphtha or clay may be used as a binder, the former being preferable as it contains no water. The coating may be applied either by a swab or through a compressed-air gun.

Field of Application of Hot-Mold Centrifugal Casting

The particular feature that determines the field of application of hot-mold centrifugal casting is the ability to produce cast shapes of comparatively thin metal (down to $^1/_8$ in.) in great lengths—with our present knowledge of the art, up to 20 ft. One of the first applications that comes to mind is in the production of seamless tubing.

Hitherto the principal tonnage of seamless tubing has been made by the Mannesmann piercing process and its variations. Essentially this process consists in imparting such a twisting motion to a steel billet as to break down its central fibers. This motion is set up by means of obliquely placed rolls or disks. There are several objections to this process. In the first place, while it does pierce high-grade mild steel or muntz-metal billets, it stresses the central part of the billet far beyond its elastic limit. While apparently this does not affect very seriously the tensile strength of the finished product after it has been cold-drawn or hot-rolled, there is good reason to believe that it impairs the resistance of the metal to corrosion, the latter, as we know now, being particularly active in the case of metals stressed up to or beyond the elastic limit. Furthermore, the Mannesmann process is not at all applicable to metals which are either extremely tough or very brittle. Thus, all attempts to produce commercially by the Mannesmann process, hollow billets of either monel metal or Admiralty brass have so far failed. Not only that, but the Mannesmann process, by its very character, is limited to the production of comparatively small sizes, not in excess of 6 in. in diameter, as the cost of a Mannesmann mill becomes prohibitive after passing that limit.

At the same time there is a demand for larger sizes of tubing of greater strength than a single-welded joint can give, and this is where the most obvious field of hot-mold centrifugal casting appears. With this process, tubing in extra heavy and double extra heavy thicknesses can be easily produced in sizes up to 24 in. in diameter at a cost per ton that can compete with plain welded tubing, and considerably lower than that of double-welded tubing such as is used for hydroelectric installations.

The next field of application in connection with steel tubing is in standard sizes from 6 to 14 in. up, where welded tubing is now used exclusively. Such pipe can be produced in two ways: First, by casting a hollow billet of wall thickness two to three times that of the finished pipe, and either cold-drawing or hot-rolling it to size. In such a case the billets cast would be roughly 8 to 10 ft. long so as to have, say, 22 ft. in the finished pipe, barring cropped ends. The other method is to cast the pipe direct with only a slight excess of wall thickness and then to give it one pass between straightening rolls over a ball, so as to reduce the diameter and wall thickness to exact size with standard tolerances, and give the exterior and interior walls a finished appearance. From data now available it would appear that the final cost of both kinds is approximately the same and is well within the range at which centrifugally cast steel pipe can compete in price with welded pipe. There is at least 50 per cent less handling of material in centrifugal casting than there is in making pipe by welding, and such a difference cannot help being reflected in costs.

In this connection it might be well to mention one of the psychological factors with which centrifugal casting is concerned, and that is the not unfounded distrust of users of metal products toward castings, especially those in thin sections. Such castings cannot be produced commercially in a stationary mold, and steel castings in a stationary mold as made today generally are of such physical properties as to be usable only where they are not subject to complicated stresses and where an extremely high factor of safety can be provided. Wherever the stresses are high and especially uncertain and the factor of safety is not more than ample, no engineer today will use a casting but will insist on either a forging or a piece machined or hot-rolled.

This not unfounded distrust of castings is due to the fact that in either the sand casting or chill casting the temperature conditions in the metal are uncontrollable, with the result that one part of the metal may be entirely different in its physical properties, such as hardness and crystalline structure, from another, and there is no guarantee that two castings made under apparently the same conditions will be entirely alike. There is too much individuality in products cast in stationary molds to make them suitable for engineering requirements where a failure would be disastrous and where only moderate factors of safety may be employed. The situation is, however, entirely different with centrifugal castings, because there ample facilities are available, especially in hot-mold casting, to control the rate of cooling of the metal, and the nature of the process is such as to tend to give a uniform product, provided, of course, the process is carried out properly. From this point of view, one cannot help agreeing with an editorial in *The Iron Age* (Feb. 9, 1922), which states that "the successful operation of centrifugal-casting processes insures a product, no

matter of what composition, which is of a high grade. It is a realization of quality production in quantity, for rapid output is a marked characteristic. There is also the advantage of the elimination of sand and dirt. The condition of casting and cooling tends to produce a dense casting and one whose microstructure is different from the sand-cast products. Centrifugal force is substituted for sink heads as an insurance against unsoundness." This brief analysis states strikingly the difference between sand castings and centrifugal castings, and explains the reason why centrifugal castings may be used on a par with forged or hot- and cold-worked metal where sand castings would be too hazardous.

But the field of application of centrifugal casting, especially of the hot-mold type, does not stop with plain carbon steels. There are a number of alloy steels which it would be very desirable to have in tube form, such as stainless steel, high-speed tool steel, chrome-nickel-vanadium steel and the various "near-steels" which are iron alloys with a predominance of materials other than iron, such as heat-resisting alloys. Practically none of these materials will stand for piercing by the Mannesmann process, but cast with great ease into tubular shapes. In fact, even Hadfield manganese steel has been found to make, by centrifugal casting, excellent tubing, although it is very doubtful it has any commercial application outside of some very limited specialties.

Plate Manufacture

Centrifugal casting is peculiarly applicable to the manufacture of plates. Andrew Shanks, a British inventor of the middle of the 19th century, to whose pioneering work in the manufacture of cast-iron pipe reference has already been made, was also the earliest manufacturer of plate. His process was to cast a thin-walled pipe, cut it, and then by careful annealing and hammering, flatten it out. The process was kept secret and was successful commercially until rolled steel sheet was put on the market.

The use of a hot mold makes it possible, however, to secure comparatively thin-walled castings in large sizes. A process has been worked out, though not yet applied on a commercial scale, in which a cylindrical casting is made in such a manner that a longitudinal split about half an inch wide is produced. The split cylinder as it comes from the mold is sent first through a flattening jig where it is flattened out on its own heat, and then to rolls, of which there are at least two, one for sizing and the other for finishing. Under certain conditions more than one sizing roll may be required. The casting has to be cast oversize, the wall thickness being from 10 to 15 per cent greater than that of the finished plate. Thus, for example, $^1/_4$-in. plate would be cast in sizes 240 in. long, 20 in. in diameter and 0.265 in. wall thickness. It is expected that it can be brought down to a thickness of $^1/_4$ in. in one pass in the sizing rolls and that no reheating will be necessary.

This process is today only in its initial stages of development. It is attractive, however, as it does away with the ingot-casting work, soaking pits, blooming mill and a great share of the rolling equipment, permitting a conversion from molten metal to finished plate at a cost estimated at about $4 per ton.

Not only that, but it also makes quite attractive the manufacture of alloy-steel plates, in particular, of such materials as acid-resisting steels for use in chemical tanks and the like. These steels are very difficult to roll. The final product could stand the cost of the two or three passes necessary in centrifugal casting of plates, but not the many operations of the conventional methods of plate manufacture, the main item of expense being not the actual rolling but the complicated heat treatment absolutely imperative between the rolling operations. In fact, it would not be surprising if with prices of alloy-steel plates brought within reason, they would be used far more extensively than one would expect to find from present indications.

Other Applications of Centrifugal Casting

The casting of gears by centrifugal methods, in particular worm and herringbone gears, has been achieved with great success both in England and in America, especially in the latter country. As far as the author is aware, however, all such gears have been cast in non-ferrous metals and not in steel.

There is one more field of application of centrifugal casting, especially the hot-mold type, comparatively small today but which may become of material interest shortly, and that is the production of cylinders requiring extremely high strength. When the oxygen industry first called for cylinders that would safely withstand 2000 lb. pressure to the square inch, it looked like a big problem, but it was solved by progress in the cupping process. When, however, the Haber synthetic ammonia process demanded great pressures combined with considerable temperatures, special expensive tools had at first to be provided for machining the cylinders required from solid stock. The Claude ammonia process employs temperatures and pressures far exceeding those of Haber, and the experiments of Professor Bridgman of Harvard University and of others all point to the likelihood that before many more years have passed pressures of the order of 100,000, 200,000 and possibly even more pounds to the square inch will be used commercially.

At pressures between those used by Haber and Claude and those used by Professor Bridgman for containers of commercial size, carbon steels are but little suitable and the vessels required will have to be made from alloy steels. This may be done in two ways, either directly by centrifugal casting on a vertical axis which would give a vessel with closed bottom, or by the cupping process from alloy-steel plates, which, in their turn, would be made by centrifugal casting as already described. In this connection it may be of interest to mention that a high measure of success was achieved during the war by the Bethlehem Steel Company at Bethlehem, Pa., in casting air flasks for torpedoes centrifugally in a machine running on a vertical axis.

No attempt has been made in the foregoing discussion of the field of application of centrifugal casting to present anything like an exhaustive list. Instances have been merely cited in order to show the enormous field in which this process is now or may be employed.

The same applies largely to the description of the mechanics of the process, where likewise no attempt has been made to show the historical development of machinery for centrifugal casting or to give details of the actual apparatus. Such machinery, it should be emphasized, is and should be comparatively simple, for the process when properly worked out is the acme of simplicity. It should be clearly understood, however, that in centrifugal casting we are dealing with large rotating masses and with metal subjected in its molten state to the effect of great force. Furthermore, the distribution of the metal in the mold is effected primarily not by rigid material visibly distributed as in stationary casting, but by the action of invisible forces which do not come into operation until the moment when the metal is delivered to the mold.

Because of all this, and notwithstanding the great simplicity of the machinery and methods of centrifugal casting, it should be clearly remembered that even the slightest imperfection in the design or operation will immediately show up in the casting. Centrifugal casting is a process which is peculiarly impossible to be worked either by slipshod methods or on a shoestring, i.e., skimping on the quality of materials and on factors of safety in the design of machinery.

There is an old saying current among molders to the effect that a lie in sand will be shown up in the metal. The same applies with still greater force to centrifugal casting. The slightest mistake in the layout of the machinery or the use of poor materials in the machine, its bearings and foundations, will produce an uneven casting, result in excessively rapid wear of the molds, and at times may even cause disastrous accidents with danger to life. At the same time, with good engineering and the use of first-class materials, centrifugal casting may be carried on entirely by semi-skilled labor and still give products of unsurpassed excellence.

[Five appendices accompanying the complete paper are devoted respectively to (1) a bibliography of the subject; (2) what is believed to be a complete list of all patents on centrifugal casting issued since 1848 by the U. S. Patent Office; (3) mathematical considerations governing casting about a vertical and a horizontal axis and the axial forces acting on the liquid metal in a horizontal mold; (4) temperature control of the metal of the casting and of the mold; and (5) fluid-pressure, fly-wheel and thermal-expansion stresses in molds used in centrifugal casting machines.—Editor.]

Hydroelectric Power-Plant Design

By J. A. SIRNIT,[1] BIRMINGHAM, ALA.

The most logical and simplest way to maintain the full capacity of a hydraulic power plant during flood periods is to remove the high tail water from the discharge opening. This may be most successfully accomplished by a backwater suppressor utilizing the waste water, and the present paper is chiefly devoted to the development and application of this method.

Two testing models are described and the results presented, while the design of the draft-tube orifice is discussed at some length. Finally the plant of the Alabama Power Company at Mitchell Dam on the Coosa River in Alabama, where the Thurlow type of backwater suppressor was first conceived and applied, is described, details of its construction and equipment being included

THERE are many power plants and possible sites for such plants where the supply of water is very irregular, and where, owing to the nature of the surrounding country, it is impossible to provide sufficient storage for the utilization of all the water flowing in the stream.

In many hydraulic power plants, now in operation or proposed, there is, or will be, a great loss of power annually, due to the fact that during flood conditions when water is being wasted over the spillway, the level of the water in the tail race at the outlets of the draft tubes leading from the turbines is raised, thus reducing the head on the turbines, and in turn their capacity and the output of the power plant. There are many notable examples of these conditions, and in some cases reduction in effective head on the turbines becomes so great at times as to completely shut down the power plant. The Hales Bar plant on the Tennessee River is an example of where these conditions occur during the spring floods.

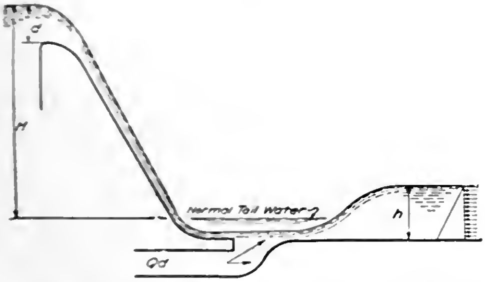

FIG. 1 ACTION OF SPILLWAY WATER ON TAIL WATER
(H = head above tail water; d = depth of water above spillway; h = total water column balanced, Qd = quantity through draft tube.)

In many cases of proposed developments, engineers have hesitated in recommending the carrying out of the development on account of backwater conditions in the tail race, which can be foreseen and predicted very closely. The proposed development at the Great Falls on the Potomac, which has been under discussion for many years, represents an example.

Engineers for many years have wrestled with this problem and have tried to overcome this difficulty by installing a greater number of generating units where it was possible to do so, to compensate for the loss in capacity of each unit; of course such a procedure necessarily makes the installation more expensive, with the resulting increase of production costs. Attempts have also been made to counteract this loss in head by admitting water into the draft tube through jets at a relatively high velocity which, by accelerating the velocity of the combined turbine discharge and jet water through the draft tube, produce a negative head which is added to the head on the turbine. A number of variations in the place and manner of introducing this jet into the draft tube have been tried and results published. But the results have not been entirely satisfactory.

The most logical and simplest way to maintain the normal head on the water wheel, and thereby the full capacity of the plant, during flood periods, is to remove the high tail water from the discharge opening, and credit is due to O. G. Thurlow, chief engineer of the Alabama Power Company, who conceived the idea of utilizing the waste water to accomplish this fact, thereby successfully solving the problem. The development of this conception resulted in what is now known as the Thurlow backwater suppressor.

THE THURLOW BACKWATER SUPPRESSOR

It is a well-known phenomenon that water flowing over a masonry dam having a downstream face of ogee section, leaves the apron in a thin sheet at high velocity. At a point below the dam the water rises turbulently, forming a so-called "standing wave," "hydraulic jump," or "back roll." The thickness of this sheet and the velocity of the water depend upon the height and shape of the downstream face of the dam, upon the depth of water at the crest of the dam, and upon the quantity of water flowing over the dam. The energy developed in this thin sheet of water has generally been regarded heretofore as solely of a destructive nature, but in the backwater suppressor the energy of the spillway water is so directed as to remove the backwater from over the draft-tube orifice, sweeping it downstream, thus freeing the draft tube from this pressure of water over it and maintaining a practically uniform head on the turbine as long as the spillway water is able to sweep the backwater away from the draft-tube orifices. In Fig. 1 is shown diagrammatically the action of the overflow spillway water on the tail water. The energy of the spillway water not only removes the height of tail water from the draft-tube orifice, but even lowers the normal tail-water level to a predetermined depth.

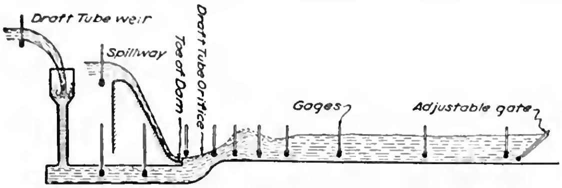

FIG. 2 DESIGN OF TESTING FLUME

MODELS TESTED

In order to substantiate the idea and evolve a definite theory on which to base the calculation, a model was constructed on a 1 : 24 scale at East Lake in Birmingham, Ala., where a small flow at 3 ft. head was available. The results obtained were so interesting that, to check the data obtained and to increase the accuracy of measurements, a second and larger model was constructed on a 1 : 10 scale at Jackson Shoals, Ala., where a greater flow and head were available.

The results obtained with the two models, when reduced to the same scale, were in close agreement and the observed results followed those calculated for similar conditions.

Fig. 2 shows diagrammatically the essential elements of these models. Each consists of a forebay for stilling the water, a spillway having the usual ogee section, a draft tube with its orifice located directly under the spillway, and a tail-water wasteway.

The heights of the water in the forebay, wasteway and draft tube were measured in glass gages conveniently located on central platforms. By means of these, measurements corresponding to the pond-level head above the river bed, the effective turbine head, the depth of water over the spillway, and the backwater head could be conveniently determined.

Weirs were used in admitting water to the draft tube so that the amount could be accurately measured. This amount was ordinarily maintained to correspond to a normal turbine discharge.

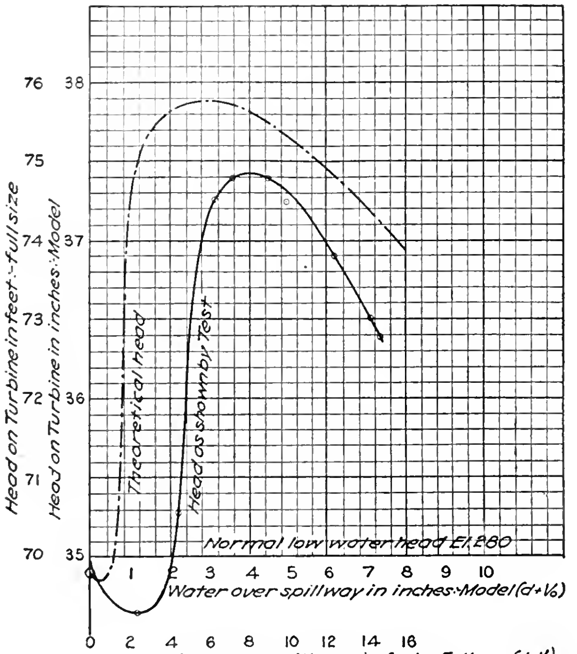

Fig. 3 East Lake Head Curve

Bear-trap stop logs were provided at the end of the wasteway by which the height of the water in the wasteway could be varied to simulate backwater.

Calculated and Observed Results

The height of the standing wave, taking a section of unit width (1 ft.) and neglecting losses due to the friction of the moving water over the spillway, can be approximated by the empirical formula $h = \sqrt{d^{3/2}H^{1/2}}$, in which d is depth of water in feet over the spillway and H the head in feet above the spillway apron. This does not take into account the effect of the turbine water. This factor will increase the height of standing wave, so that the actual results will be somewhat better than as shown by the formula.

The figures of Table 1 were compiled from three separate tests made at different times and show the performance of the Jackson Shoals model with 18 in. of water over the spillway in suppressing various heads of backwater.

The effect on the turbine head of different amounts of water over the spillway of the East Lake model is shown in Fig. 3. It should be noted that very small amounts cause a decrease in head because sufficient velocity has not been given to the draft-tube water to cause a thinning of the sheet over the draft-tube orifice, but when the ratio of spillway to draft-tube water increases to about 1 : 1 the curve takes a decided course upward and reaches its peak and starts falling off again due to a greater quantity of water passing over the orifice, with practically no increase in velocity above that of the point of maximum head. This curve does not represent the best performance possible but it is typical of the ideal theoretical curve which is shown in the same figure.

The curve in Fig. 4 shows the overall performance of the test as compared to that without the suppressor. It will be noticed that the head drops off slightly as the backwater increases, due to a greater quantity of water necessary to hold the standing wave, until a point is reached where the standing wave is 13.26 in. high and the curve turns sharply down. This point represents the critical stage or the maximum height of backwater capable of being suppressed by a given amount of spillway water. This could be increased by having a design of spillway permitting a greater discharge.

Even after this point is reached a substantial increase in head is obtained, and at the last point plotted, with backwater 50 per cent of the total head, an increase of 5 in. is recorded. Fig. 5 illustrates the condition of backwater after the critical stage has been passed.

Design of Draft-Tube Orifice

Several shapes of draft-tube orifices were tested. That shown in Fig. 6 leaves very little to be improved upon for getting a maximum height of standing wave and a maximum head on turbine. This design can be modified to give a greater head on the turbine, but only at a sacrifice in the height of the standing wave.

The location of point x is of great importance as it controls the increase in head on turbine, and its relation to the elevation and angle of discharge of the spillway apron must be very exact or a poor performance will result; also consideration for the turbine "run-off" during the period when the suppressor is not in action must be kept in mind.

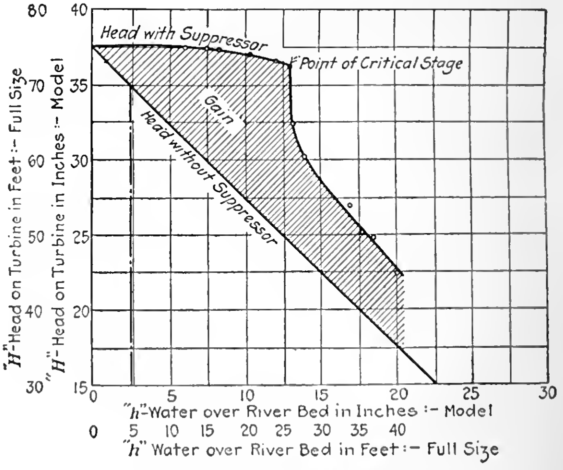

Fig. 4 East Lake Performance Curve

The length of tangent t must be such that it will direct the spillway water well along the line ab, and it should be at least 5 ft. for heads up to 25 ft. and 7 ft. to 10 ft. for heads varying from 30 to 100 ft. The amount of water flowing over the spillway will cause this length to change, but for depths up to 15 ft. this range will hold good.

The distance out of point x is determined by the amount of water passing through the draft tube. The area of the draft-tube orifice subject to the action of the sheet of spillway water must be proportioned so that a back pressure in the draft tube is not necessary to force the two waters to mix. The curve of R_3 is great enough so that the centrifugal force of the fast-moving sheet of water will not cause it to leap clear of the concrete surface. R_2 makes a smooth transition, connecting point x and R_3, and is about $^1/_2$ R_3.

The standing wave is held out just beyond tangent R_3. The total distance from the lip of spillway apron to the point of wave must not be greater than good design of the other features will permit, as the friction of the high-velocity water diminishes the height of the standing wave, thereby causing a greater amount of waste water necessary to operate.

The river channel below tangent R_3 must be finished with neat concrete for a distance of four heights of the standing wave, in the case of heads up to 25 ft., and five to six heights for heads varying from 30 to 100 ft. This is necessary for good performance although a rough bed or water pocket can be used, but a great waste of water is required and heavy undercurrents, due to an imperfect standing wave, might scour the river bed badly or undermine the protecting apron.

This is of great importance if the rock strata are poor, as open seams will allow the high static pressure beyond the wave to be transmitted back under the protecting apron, causing an uplift. This uplift must be given attention, even when the apron is carried out to the desired point and provision made for its secure anchor.

Dividing Walls

Each unit must be provided with dividing walls to prevent the water from coming in on the sides and to allow any one unit to operate independently.

The correct height and length of these walls is determined by the backwater and discharge curves of the river at the location of the power house. Section A-A, Fig. 6, shows the condition for the installation of four units. The three intermediate walls are at an elevation shown by the backwater curve when the required amount of water to operate four turbines and three suppressors is passing that point. When the fourth suppressor is brought into action the condition is as shown by the dotted line in unit No. 2, and these walls simply act as a guide to hold better conditions at the point of wave and prevent surging.

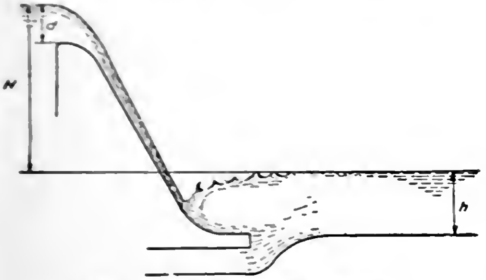

Fig. 5 Flood Conditions of Model

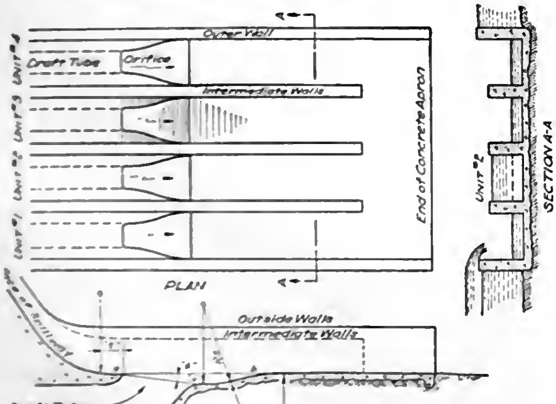

Fig. 6 An Excellent Design of Draft-Tube Orifice

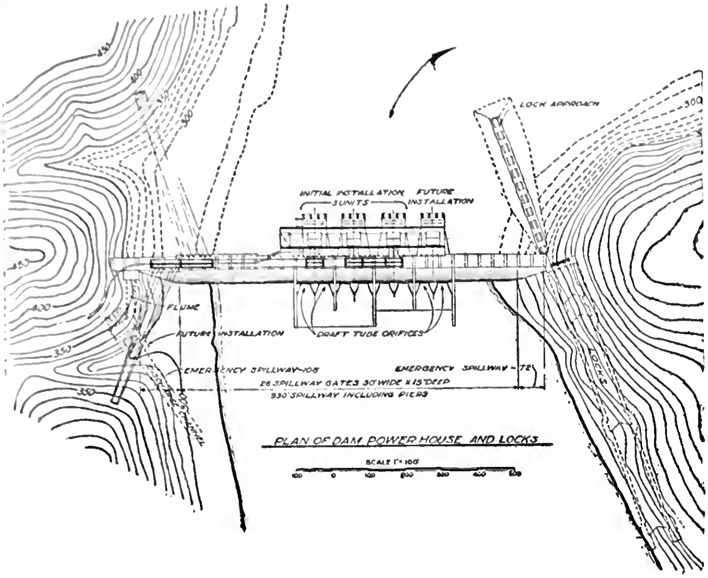
The two outer walls are designed for extreme flood conditions, as any water passing over the walls into the suppressor sheet will cause a loss in head on the turbine and in height of standing wave. However, if there should be spillway gates on both sides of the power-house section equal to the width of two units, it need not be at the maximum high-water elevation, but at the stage shown by the combined discharge passing the power house and side spillway. This is due to the fact that although a perfect standing wave is not formed at the toe of the side spillways, a lower elevation is created than will be further downstream, where the true backwater elevation is measured.



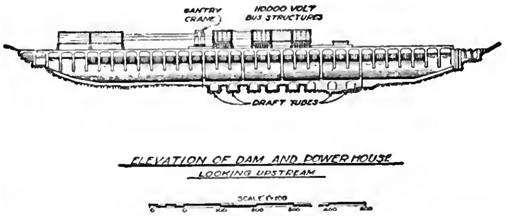


Fig. 7 General Plan and Elevation of Alabama Power Company's Dam and Power House on the Coosa River

Power Plant with Backwater Suppressor

Encouraged by the splendid results of the model tests and the economic advantages of the undertaking disclosed by careful analysis, the Alabama Power Company decided to apply the backwater suppressor at Mitchell Dam on the Coosa River in Alabama, which is now under construction. The estimates showed that not only was the cost of the suppressor-type plant not higher than that of a conventional-type plant of equal output, but even lower in cost for the same number of units, and therefore for a given output the suppressor-type plant was considerably less expensive.

The principal and most outstanding feature in this plant is the location of the power units on separate foundations in the river on the upstream side of the dam (Fig. 7). Although this was not necessarily the only possible way to build the power house, it was the most economical. The river at this point being comparatively narrow, the entire length of the dam was required for spillway, and since the prime requisite of this type of plant is that the draft-tube discharge directly under the spillway section, the units had

to be so located that they would not obstruct any part of the spillway section.

The individual and separate power-house units offer the added advantage that trash racks do not present a solid front, which helps materially in cleaning them and affords an easy and convenient way of diverting the trash past the power house and over the spillway.

The usual power-house building is entirely eliminated. The generator room is covered with a low roof, which is designed in two sections, joined on the transverse line, mounted on rollers; each section moving in opposite direction. In normal operation the generator room is completely protected from the weather, but for handling large parts of the machinery, this roof can be opened and a crane utilized for performing the necessary work.

A single gantry crane (Fig. 7) with full travel over the entire length of power-house section is so designed that everything, with the exception of spillway gates, can be handled by it. It is equipped with one 125-ton and one 20-ton hook, the former for handling heavy machinery and the latter for raising and lowering penstock gates, handling racks, stop logs and all other lighter parts.

An outdoor transformer and high-voltage switching station is located on the bridge over the spillway (Fig. 8). This plant is designed for operation on unit system, i.e., the generator and its bank of step-up transformers are connected as a unit and all principal switching is to be done with the high-voltage circuit breakers. In stations where units are of large capacity, as in the 20,000 kva. plant under discussion, the unit system is very economical and preferable, as it presents the simplest, yet sufficiently flexible, form of operation.

The entire operating floor is on one floor level. The generators, governors, switchboard, low-tension switches, bus galleries and offices are easily reached without climbing stairs or ladders. This materially adds to the convenience of operators and makes the supervision and inspection of the plant more effective. This feature of providing easy accessibility to all important parts of the station is very frequently lost sight of by power-house designers and the lack of these conveniences has been the cause of inefficient operation or even of breakdowns, due to the fact that operators have neglected the equipment to a lesser or greater degree.

The generators are so installed that the hot air from the generator is discharged into a separate compartment under the main floor and is expelled into the atmosphere through side openings of that room in summer time, thereby keeping the generator room reasonably cool. In winter, however, when heat in the rooms is desired, the outside openings can be closed and through registers in the floor the warm air enters the generator room.

The penstock does not represent a true scroll casing but rather a combination of scroll effect and open flume. The water velocities in the penstock being low, approximately 4 ft. per sec., this combination affords a better design.

The location of power-house units on the upstream face of the dam lengthened the discharge tunnel to a distance of about 120 ft. from the center line of the unit. Although the velocity of the discharge is only 4 ft. per sec., the effect of this long column of moving water had to be carefully investigated and studied. This problem was solved satisfactorily by increasing the governor action to $3^1/_2$ sec. and setting the turbine to the lowest practical level. Turbine settings always should be as low as possible, especially where improved draft tubes are employed. Many of the troubles in existing power plants, such as pitting of runners, excessive vibration, etc., can be directly traced to high wheel settings, particularly with high-specific-speed runners.

Fig. 7 shows that 26 spillway gates of the Tainter type are provided, each 15 ft. high and 30 ft. wide. These gates are capable of passing the maximum flood water known to have existed in the past. There are also six bays, two on the east and four on the west end of the dam, which are designated as emergency spillway openings. The crest of these openings is level with the top of the spillway gates and their function is to provide additional spillway capacity in case of unprecedented floods when water would rise above normal pool level.

Although little has been said about the electrical equipment, it is one of the most important parts of the installation and should always receive close study and serious consideration if economical and efficient operation is expected.

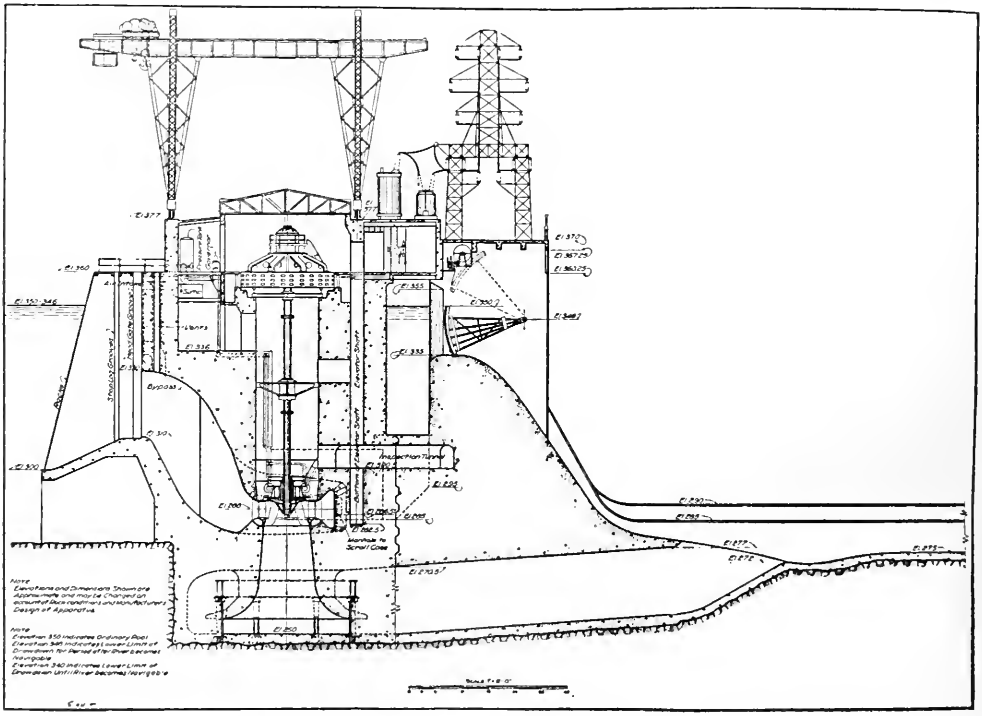

Fig. 8 Cross-Sectional Elevation View of the Power House Shown in Fig. 7

The Boiler House of the American Sugar Refining Company at Baltimore, Maryland

By E. B. POWELL,[1] BOSTON, MASS.

TO AN industry such as the refining of sugar, the proper functioning of the boiler house is altogether vital. Almost every phase of every process in the refinery is directly dependent upon the application of steam as a heating or drying agent. For this reason, also, the cost of steam is an important factor in the manufacturing costs of the refinery.

In the design of the boiler house for The American Sugar Refining Company at Baltimore, the effort has been made to combine a high degree of dependability, efficiency and simplicity in operation and agreeable conditions of work, in a type of construction readily adaptable to the economic requirements of any permanent or long-term condition of fuel market, such as might call for the installation of economizers in any form, or the substitution of any other class of fuel than that initially selected.

The steam requirements estimated for the present developed capacity of the refinery were about 7,300 boiler-hp. average, and 8800 boiler-hp. maximum, demand. It was also considered that further developments might possibly increase the steam demands by about 50 per cent. The general suspension of refinery operations over Sunday would allow opportunity for any minor repairs that might be required in the steam-generating equipment, so obviating the necessity for much duplication in reserve, and permitting the economic adoption of moderately large units even for the initial development. On these bases, 6000 rated boiler hp. in 1200 hp. units was decided upon as the most suitable capacity to be installed for present requirements and 9600 rated hp. as the probable ultimate capacity of the boiler house.

A careful survey of the possibilities of all fuels considered commercially available led to the selection of a grade of small-sized anthracite, popularly known as "creek coal," as most satisfactory and economically meeting the requirements. This coal is not only low in price and, for practical purposes, entirely free from deterioration in storage but possesses as a fuel for the refinery boiler house the additional and important advantages of cleanliness—the refinery is turning out an essential food product of the highest quality—and of permitting the adoption of a single fuel for the entire plant—anthracite is required in the refinery processes for firing the bone-charcoal regenerating kilns. The major equipment of the boiler house, however, was designed for ready adaption to any type of fuel.

General Features of the Plant

Fig. 1 shows the refinery boiler house and outdoor coal plant as viewed from the Patapsco River, and Fig. 2 a representative cross-section. The building is of structural steel frame with brick walls and reinforced-concrete flooring, the basement being at the grade of the lot and the main operating floor about 28 ft. above. The structure is 111 ft. 5 in. wide by 132 ft. 10¾ in. in length with a height of about 125 ft. from the ground level to the top of the coal-bunker housing. The building footings rest on a continuous concrete mat foundation supported on wood piling closely spaced.

The main operating floor is practically clear of all equipment, except the boilers and stokers themselves. Liberal aisle space is provided to give convenient access at all points. Also, to minimize attendance, practically all the auxiliaries of the station are grouped together on the mezzanine and basement floors under the west line of boilers. The space under the east line of boilers is utilized for offices, toilet and locker rooms, laboratory, tool and storeroom, raw-sugar electric-truck charging station, and repair shop.

The boiler-house stacks are of reinforced concrete, 200 ft. high above the roof, 15 ft. in internal diameter, and supported on the building frame at the roof level. The coal bunker is of reinforced concrete, of the longitudinal type, set above the firing aisle and having a capacity of about 1200 tons, or three or four days' estimated normal requirement. To provide for ample daylight illumination, the bunker is raised somewhat higher than is usual and continuous skylights are set at either side, which admit a full flood of light into the boiler aisles.

The main coal storage is provided out of doors in the lot space bordering on the water front and to the east of the boiler house. Coal is normally delivered by rail to the B. & O. R.R. pier head, where it is discharged on to refinery-owned barges of about 700 to 800 tons capacity. The loaded barges are warped alongside the refinery coal wharf with the aid of electrically driven winches and are there unloaded, either directly to the station or to the yard storage, by means of an electrically operated movable tower of the through-boom type carrying a 2-yd. bucket of 150 tons' hourly capacity. The movable tower has a storage and reclaiming capacity of about 9,000 tons immediately beneath the boom; the remainder of the 25,000-ton outdoor storage capacity is served by locomotive crane.

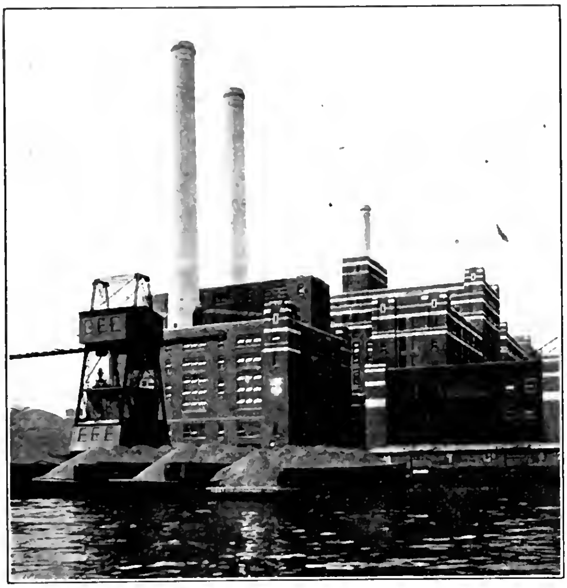

Fig. 1 The Boiler House of the American Sugar Refining Company at Baltimore, Md., as Viewed from the Patapsco River

Coal intended for the station bunker is delivered by the movable tower on to a 30-in. trunk-line belt conveyor which in turn delivers to the double-chain fixed-bucket-type elevating conveyor at the north end of the boiler house. From the latter conveyor it is distributed to the different sections of the bunker by means of a 24-in. belt conveyor and automatic tripper. From the bunker, coal is delivered to the stoker hoppers by an electrically operated automatic weighing larry. A separate pocket is provided in the boiler-house bunker for coal intended for use in the filter-house kilns; this coal is conveyed to the filter house by special overhead belt conveyor and weighed on automatic weightometer en route.

Steam leaves the boiler house and condensate, hot and cold water, and compressed air from the refinery reach the boiler house over a bridge near the northwest corner and at a level slightly above that of the mezzanine. The main steam header within the boiler house is in the form of a loop with one side carried above the east line of boilers, the other side accessibly located at the rear of the west line of boilers about three feet above the operating floor.

---

[1] Consulting Engineer, Stone & Webster. Mem. Am.Soc.M.E.

Paper presented at a joint meeting of the Baltimore, Md., Sections of the A.S.M.E. and A.I.E.E. and the Baltimore Engineers' Club, May 24, 1922. Slightly abridged.

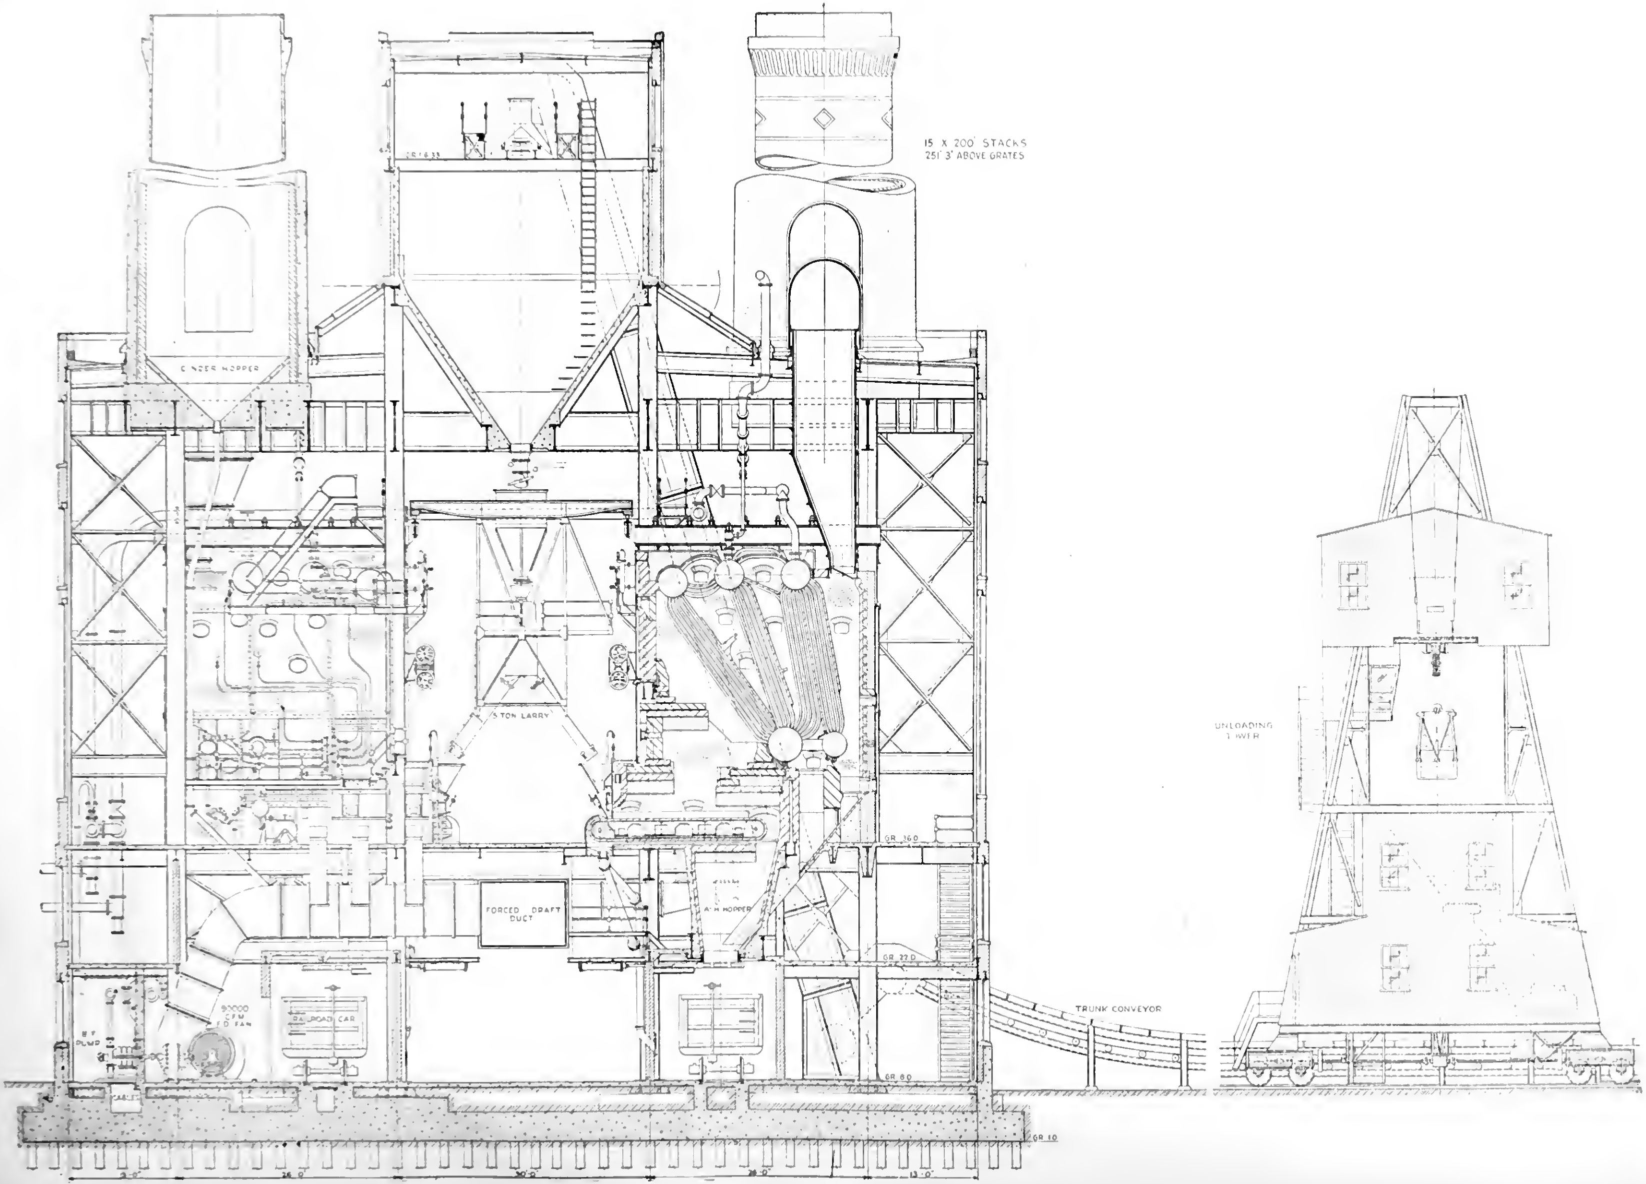

Fig. 2 Typical Cross-Section of Boiler House

At the point of take-off for the two lines which lead respectively to the engine house and to the refinery, provision is made for opening the loop and feeding these two lines separately, with a regulating valve between set to maintain the desired pressure in the engine-room main. In normal operation, one of the division valves in the boiler-house loop will be closed to segregate to the engine-room main the boiler capacity required to carry the power load, the remainder of the boiler capacity on the line feeding through the other side of the loop to the direct-refinery main in which any pressure above 110 lb. will meet all requirements. With this arrangement sudden demands in the refinery can produce only negligible drop in pressure at the engine house, and such loss of pressure as may occur in the refinery main may readily be regained before there is any interference with manufacturing processes.

The Boilers

The boilers are in 1206-hp. units, Stirling type, with 26 per cent integral economizer surface and are encased in settings which, except for the rear wall back of the integral economizers, are of solid firebrick. There are no superheaters. The boilers are designed for 250 lb. pressure and will normally operate at about 210 lb. They are equipped with 18-element mechanical soot blowers and with automatic feedwater regulators. To avoid risk of corrosion the interior surfaces of all boiler drums and of economizer sections complete, both tubes and drums, are treated with a special carbon coating. This coating has been applied as a measure of extra precaution, as under normal conditions all air and other gases will have been removed from the boiler feed and there should be no tendency to corrosion in any form.

Flues and uptakes are of steel plate with 2 in. of inside insulation. Provision is made in the space above and at the rear of the boilers, including the space now occupied by uptakes, for the installation of additional economizer surface or of air heaters, should either prove desirable in future, and for cinder catchers, should the need for such apparatus appear.

The stokers are of the traveling grate type, two per boiler, with an effective surface for each stoker 9 ft. $8^3/_8$ in. in width by 16 ft. 4 in. in length, giving a ratio of grate surface to heating surface of 1 : 38. Each stoker is driven by a $2^1/_4$–3-hp. d.c. motor with hand-operated drum controller.

The ash hoppers are of reinforced concrete, brick-lined, providing capacity sufficient for about 16 hours' requirements and so set as to give ample clearance for the standard railway car of full gondola size beneath. The ash gates which form the bottoms of the hoppers are operated by air cylinders and designed to discharge directly into the railway cars.

All auxiliaries, except one feed pump for emergency and starting purposes, are electrically driven by d.c. motors. Four centrifugal feed pumps are installed in the west basement: two motor-driven of 750 gal. per min. capacity, and one motor-driven and one turbine-driven of 350 gal. per min. capacity. Forced draft is supplied by three turbovane-type fans of 90,000 cu. ft. per min. capacity at $5^1/_2$ in. pressure, driven by 125-hp. motors under automatic control from the steam-line pressure. These fan sets are located on the basement floor under the west line of boilers and draw the bulk of their air supply from the ash alleys. Adjustable louvres opening into the fan bays from the west mezzanine are, however, provided for ventilation. For cleaning purposes and for operation of ash gates, damper regulators, and other devices of a 200 c.f.m. motor-driven air compressor is provided which is located with other auxiliaries in the west basement. Reserve air supply is had by pipe connection with the compressor plant of the refinery.

The Feedwater System

As practically all steam leaving the boiler house, including that used for power purposes, is condensed in closed coils in the refinery and so normally available for boiler feed, the feedwater make-up requirements estimated are but slightly greater in percentage than those of the modern condensing-type electric generating station. To meet the accidental condition of evaporator-coil leakage, or other cause of contamination or loss of condensate, however, it has been necessary to make provision in the feedwater equipment for the emergency use of raw water exclusively.

Under normal conditions, condensate will be returned from the refinery at a temperature of between 180 and 220 deg. fahr.; the raw make-up water will normally reach the boiler house at city main temperature, about 50 to 70 deg. fahr. The condensate returned to the boiler house is first passed through standard toweling-type filters to remove any suspended impurities; from the filters it discharges into a 12,000-gal. receiving tank located on the west mezzanine. The normal make-up, direct from the city mains, is delivered first to a deaerator having a capacity of 21,000 lb. per hour and located above the receiving tank and on the west wall of the boiler house. In this apparatus practically all dissolved oxygen and other gases are removed. The deaerated water, so called, is delivered direct to the receiving tank under float control at about 190 deg. fahr. A 15,000-gal. storage tank equipped with float seal to prevent air contamination is set in the northwest tower of the boiler house to provide a reserve supply of deaerated water for boiler-filling purposes and to meet all except the most unusual or emergency demands. At times of low make-up requirement this storage tank will be filled. Its contents at all times are indicated by pneumercator gage conveniently located on the wall of the west mezzanine. The supply from this reserve storage is fed into the receiving tank automatically, as required, through a float-operated valve. Two emergency supplies are provided, one from the hot-water system of the refinery, the other direct from the city mains, both under float control, the latter at the lower level. The emergency supply direct from the city mains is delivered to the receiving tank through a closed-type high-pressure heater. The opening of the float-controlled valve on this line caused the simultaneous opening of a motor-operated valve admitting steam to the emergency heater, after which, regulation of temperature is under thermostat control. When the float-operated valve closes off the emergency supply to the receiving tank it at the same time causes the motor-operated valve to cut off steam to the emergency heater.

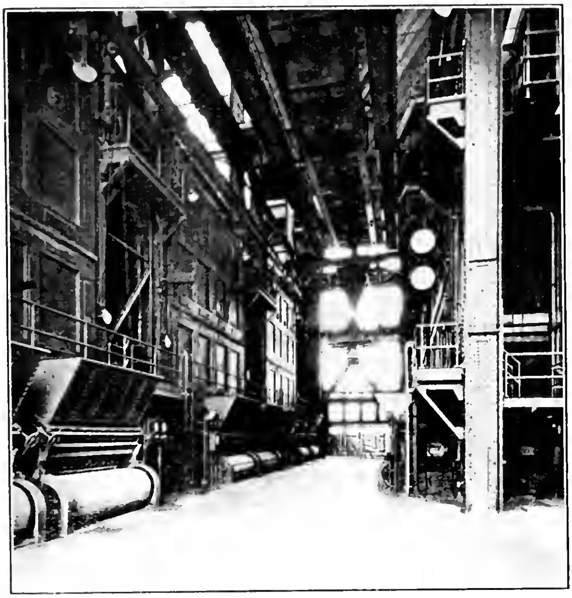

Fig. 3 The Firing Aisle

Condensate from the high-pressure mains in the boiler house is taken care of by a Holly system, which of course returns this condensate direct to the boilers. Condensate from the low-pressure or exhaust mains in the boiler house is collected in traps which discharge directly into the return tank in the engine house and are returned to the receiving tank with other condensate through the oil filters.

Instruments

The more important instruments employed in gaging the boiler and furnace performance—two electric tachometers to indicate the grate speed of each stoker and a boiler meter recording steam out-

put, rate of air flow, and flue temperature—are mounted on a small slate panel at one side and immediately in front of the several boiler units. For guidance in adjustment of drafts, multi-reading draft gages are mounted, one at each side of the boiler in convenient view of the stoker blast-box damper levers and a third gage at the rear of the boilers beside the exit damper control.

Illuminated master gages, mounted at either side of the main operating aisle and about midway of the ultimate length of this aisle, indicate, on the one hand, the pressure carried in the two distributing mains leading from the boiler house to the engine house and direct to the refinery, respectively, and on the other, the rates of steam flow in these two mains. The steam flow through these mains is also recorded by meters which are mounted on a small slate panel beneath the corresponding master gages and of general design and position to harmonize with the boiler-meter panels referred to above. An illuminated number signal, operated from the vacuum-pan floor in the refinery, gives the fireman advance warning of major changes in load. There are also numerous indicating and recording thermometers and gages which are required in following the performance of the feedwater system and other details of the boiler-house equipment.

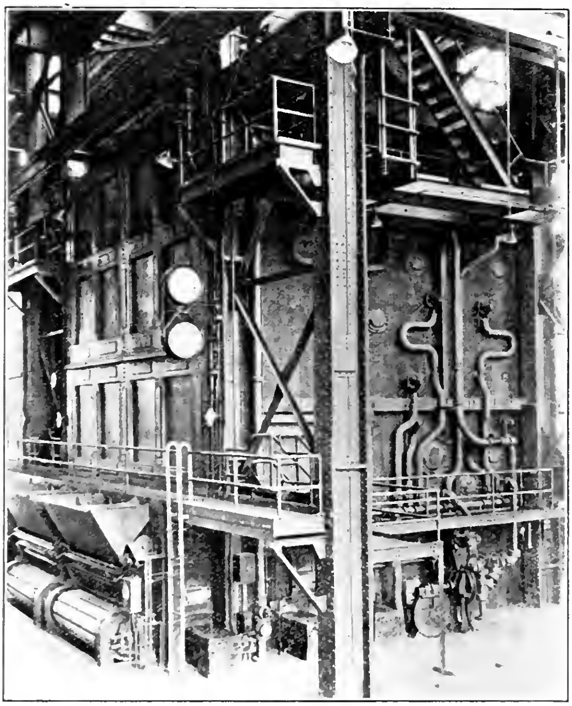

FIG. 4 ONE OF THE BOILER UNITS, SHOWING ARRANGEMENT OF ACCESSORY EQUIPMENT

SELECTION OF BOILERS

The refinery type of load, while including a fairly large proportion of power of reasonably stable demand is subject to relatively wide fluctuations which may come at any time of day as the vacuum pans are cut in or cut out. For this reason it is necessary to carry continuously in service sufficient steam-generating capacity to take care of the maximum demand, this steam-generating capacity on the average being operated at only moderate ratings. For this service the Stirling integral-economizer-type boiler was selected as combining, with low first cost, very high efficiency at all moderate ratings, exceptional ease of inspection and maintenance, and, with the steam take-off from the rear drum as here adopted, remarkable freedom from tendency to prime under sudden heavy demands. Also, for the peculiar requirements of anthracite in the small sizes decided upon for the Baltimore refinery, this general type of boiler possesses, over any other type of approximately equivalent efficiency, the added advantages of wider grate space and of presenting to the furnace gases steeply inclined tubes, which experience with anthracite has demonstrated are less liable to heavy coating and clogging of the heating surface from deposits of slag and ash than the tubes of boilers of the so-called "horizontal water-tube" type.

THE COMBUSTION EQUIPMENT

In determining upon the method of combustion, the traveling-grate stoker was decided upon as the most satisfactory type of combustion equipment commercially available for the particular coal selected. However, the plant design provides for later adaptation to pulverized-coal firing if desired.

One of the most serious difficulties, or more aptly perhaps, one of the most serious sources of loss, encountered in the use of very small-sized and so-called "creek" anthracite for boiler fuel has been the high percentage of the material that has remained unconsumed—either discharged over the end of the grate with the ash or carried by the gases beyond the zone of combustion to be deposited in some cooler part of the boiler, or over the surrounding neighborhood. One of the chief defects, seemingly inherent in the traveling-grate type of stoker, has been that of gas stratification, insufficient mixing of gases so that in the usual case, gases given off from that part of the fuel bed near the front, in other words, near the entrance of the furnace, carry a relatively high percentage of combustible constituents, as CO for example, with insufficient air for their combustion, while those gases from the rear of the grate carry an excess of unused air and oxygen.

Boiler furnaces in this country have, with two or three exceptions, been of box-like construction—for a traveling grate, two boxes connected together,—offering but little interference with simple stream-line flow of the gases. With such an arrangement of furnace, operating beyond the most moderate ratings, the richer gases from the front of the grate rarely find the full air requirement until they have passed over a part of the heating surface so that combustion if not already extinguished must continue through the boiler, resulting in loss to efficiency and, occasionally in exaggerated cases, serious damage to the boiler plates and other parts not designed for direct contact with intense flame.

The arch arrangement used in the furnaces of the refinery boiler house, and shown in Fig. 2, is intended as a step toward overcoming these several sources of loss and inefficiency. The rear arch deflects the gas flow over the corresponding portion of the grate surface, from a generally rearward direction, toward the front of the furnace and by so doing checks the shower of fine unburned particles into the ashpit—a phenomenon characteristic of the combustion of small-sized anthracite in the usual type of furnace—and gives opportunity for the lean gases from the rear of the grate to combine with those from the front. The width of throat between front and rear arches is so proportioned that some degree of mixing of gases is forced to occur except at the very lowest ratings. The presence of the rear arch, by its radiating and reflective capacity, also tends to increase the rate of combustion at the rear of the grate and so further reduce the carbon loss to the ashpit.

As the rear arch is not only exposed to the most intense heat of the furnace, but also projects directly into the furnace at the hottest zone, it was considered necessary to provide forced ventilation. Air for this purpose is obtained direct from the blast duct, and after traversing the rear arch, passes forward through the side and center walls to be finally discharged into the furnace at the rear face of the lower front arch where it serves to aid combustion of the rich gases traveling close under the arch from the front of the furnace. The final mixing of gases occurs under the upper front arch which also forms a deflector to throw the gases into the boiler-heating surface. The intention has been that the mixing zone between the lower front and rear arches and the upper front arch by affording increased intensity of combustion at this point, would not only hasten combustion of evolved gases, but also promote combustion of those solid coal particles normally carried off the grate by the draft.

Preparations are now under way for complete tests of one of the boiler units. In connection with these tests it is intended to make thorough trial of the creek anthracite of several different degrees of fineness. The tests are planned to develop not only the relative commercial values to the refinery of these different coal sizings, but also the general characteristics of a furnace of the design shown.

The Utilization of Waste Heat

A Group of Papers Dealing with the Application and Performance of Waste-Heat Boilers, and the Utilization of Waste Heat from Blast and Open-Hearth Furnaces and Cement Kilns

GREAT progress has been made in recent years in the development of methods of utilizing waste heat, especially in the steel and cement industries, and serving a region in which these products are extensively manufactured, the Lehigh Valley Section of the A.S.M.E. appropriately devoted its meeting of October 11, 1921, held at Bethlehem, Pa., to a consideration of this growingly important subject. Three papers embodying much valuable information were presented, namely, Waste-Heat Boilers, by H. B. Smith of the Babcock & Wilcox Co., New York, N. Y.; Utilization of Waste Heat in the Steel Industry, by A. T. Lewis, of the Bethlehem Steel Co., Bethlehem Pa.; and The Utilization of Waste Heat from Rotary Cement Kilns, by Joseph Brobston, vice-president, Dexter Portland Cement Co., Nazareth, Pa. The texts of these papers, slightly abridged, immediately follow.

THE APPLICATION AND PERFORMANCE OF WASTE-HEAT BOILERS

By H. B. SMITH,[1] NEW YORK, N. Y.

SO MUCH has been written within the past few years on the theory of the modern design of boilers for the utilization of heat in the waste gases from various industrial furnaces that there is little or nothing new that can be added. The present paper, therefore, will deal wholly with the application and performance of waste-heat boilers.

The company with which the author is associated has at the present time installed and in operation in connection with the various types of industrial furnaces, waste-heat boilers of a total capacity of 153,499 rated boiler hp., distributed as follows:

Open-hearth furnaces	102,211	Glass tanks	1,716
Cement kilns	15,831	Copper-refining furnaces	1,347
Beehive coke ovens	11,730	Nickel furnaces	922
Zinc furnaces	8,740	Lime and dolomite furnaces	848
Heating furnaces (various types)	4,243	Malleable-iron furnaces	373
Oil stills	3,975	Silicate furnaces	232
Gas benches	1,328		

Generally speaking, three classes, or designs, of the Babcock & Wilcox boiler are ordinarily offered for waste-heat work, namely, 18-high, 3-pass boilers for such types of industrial furnaces as require a comparatively high draft for their operation, this draft varying from 1½ in. to 2½ in. water column; 24-high, 3-pass for furnaces requiring a draft of 1 in. water column or less; and 27-high, single-pass boilers where the draft requirements of the primary furnace are very low, and where such requirements and the frictional loss through the boiler can be met with a natural-draft stack. Further, such boilers are offered where a direct connection to the primary furnace is possible. The single-pass boiler, strictly speaking, is not of the modern waste-heat design, but it has its special field which will be discussed later.

The flues and valves connecting the furnace and the waste-heat boiler must be of such construction that the air infiltration and radiation may be kept at a minimum. As a rule very little difficulty is found with radiation losses, but the air infiltration in every plant is, without exception, a difficult problem. Of course, it is possible to install a fan and fan turbine of sufficient size and capacity to overcome all of the air infiltration, but if this is done the net steam output of the installation may be reduced to such a point that the return when figured in dollars and cents will not warrant the investment.

Draft and the resistance of the gases passing through a boiler are two of the important factors in waste-heat-installation design. The draft loss is a function of two factors, the loss due to frictional resistance and the loss due to the passage of gases over and under the baffles. In order to obtain the greatest net amount of steam from the boiler, the draft required at the entrance to the boiler and the draft loss through the boiler should be so proportioned that when a steam turbine of minimum water rate for this class of machine is used to drive the fan, the exhaust steam from this turbine will not be greater than can be absorbed by the water in heating all the water consumed by the boiler to 210 deg. fahr. With such an arrangement there is a thermal loss which, when expressed in boiler horsepower, will be approximately 2 per cent of that generated by the boiler.

Whether or not an electric motor should be used in place of a steam turbine for the fan drive is a question that must necessarily be solved in each individual case. The items involved in such a question are the amount of hot water or the exhaust steam available for heating the water, the economy of the electric generator, and the reliability of the electric service. In regard to the latter, it would not be good engineering to equip, say, eight or ten open-hearth furnaces with waste-heat boilers, the fan drive for which is an electric motor, and not be doubly sure that the current would not be interrupted from time to time.

Failures Due to Lack of Attention

"Because of the war" is an expression much used when citing causes for trouble and sometimes failure, and to this same cause can be attributed in a large measure the failure of some of the users of waste-heat boilers to give proper attention to the upkeep of their installations. This failure has come through the customer's abnormal drive for output which has affected not only the waste-heat-boiler installations but the apparatus of the entire industrial plant as well. Another thing which has contributed to the inadequate attention has been the more or less unreliability of the labor obtainable.

As an illustration of the result of lack of attention given waste-heat installations, there were installed in a steel mill in 1917 a number of waste-heat boilers in connection with open-hearth furnaces. In May of the following year after the boilers had been operated some four months, evaporative tests were run to determine for the customer just what he was obtaining in boiler capacity. The tests showed an average of 445 hp. per hour from a 75-ton furnace, or an average of 70 boiler hp. per ton of steel per hour. At the coal and labor costs existing at the time, a horsepower was worth in this plant approximately $110 a year, showing a return of $49,000 a year per furnace, or at least 50 per cent return on the investment. But little was heard from this plant until less than a year ago, when a complaint was received from the customer that the boilers had fallen off in efficiency to such an extent that they were only attaining 250 boiler hp. per hour, which was a reduction of over 40 per cent. Coal and labor costs existing in the plant at the time of the complaint as compared with those of 1917 were not available, but the loss resulting from the reduced capacity is obviously great. The complaint was investigated and conditions were found such that an engineer was placed in the plant to thoroughly overhaul one of these boilers and put it in good operating condition. This work required five weeks with a gang of three to five men. From this one can appreciate the extent to which the installation had been neglected and realize the tremendous loss which resulted from neglect to properly care for the boilers.

Upkeep Costs Low

There is every reason to believe that the upkeep cost of waste-heat installations are very low, for, taking them as a whole, it will be agreed that because of the low-temperature gases which are encountered the tube losses from blisters will be rendered practically negligible, if not impossible. These low-temperature gases also result in a minimum brick deterioration, and in practically all cases the brick replacement cost should also be negligible. The only class of waste-heat work where brickwork upkeep cost need be considered is in the open-hearth field. While there are systems

---

[1] Babcock & Wilcox Co. Mem. Am.Soc.M.E.

of reversing valves which entirely eliminate the possibility of explosions in open-hearth waste-heat work, the use of such systems is not general, and with the valve reversing systems in common use it is practically impossible to prevent an occasional explosion. These explosions vary in intensity and have under certain conditions been sufficiently severe to blow out the side boiler wall, and in one instance to break off the header doors from the hinges.

Types of Boilers Used in Steel Works

The simplest form of Babcock & Wilcox waste-heat boiler offered is of the single-pass short-tube type, usually 9 to 11 ft. in length and 27 tubes high with a stack located on top of the boiler setting. This type of boiler is particularly applicable to furnaces requiring a low draft for operation and high gas temperatures as the gases leave the furnace. By high gas temperature is meant a temperature considerably in excess of that encountered in open-hearth and cement work, yet below that encountered in coal- and oil-fired furnaces. It does not follow, however, that such a boiler could not be used with temperatures from 2500 to 3000 deg. fahr., for with these temperatures and the very low draft required the boiler would show a high efficiency. As a matter of fact, the higher the temperature of the gases entering the boiler, the higher will be the efficiency of this boiler.

The arrangement of heating surface is such that there is a very low draft resistance, and further, this arrangement is such that the boiler in itself serves as a stack. In other words, if there were no stack located on top of the boiler setting there would be a draft of from probably 0.05 in. to 0.1 in. in the furnace from this boiler with gases entering it at 1800 deg. or above.

This type of boiler was developed many years ago for waste-heat purposes and a large number of them were installed. It was looked upon as an efficient boiler for the purpose for which it was designed, but the change in operating conditions, in the furnaces, etc., to which it was attached, caused it to become less satisfactory and for quite a considerable period practically it was not used. During the past few years, however, several installations have been made under proper conditions which have resulted most satisfactorily and in very economical installations.

The following figures which are taken from a test conducted at a plant in Pittsburgh where the old type of puddling furnace is still in use, show what may be expected from a boiler of this design installed where conditions are suitable for the single pass. The boiler tested was a 7-wide, 27-high, 9-in. tubes, having a total heating surface of 1880 sq. ft. There was a stack on top of the setting 75 ft. by 36 in. The boiler was operated at 122 lb. pressure and developed 220 hp., which, it will be noted, is slightly over rating. The temperature of the escaping gases was 501 deg. and the amount of coal fired (moisture content 2.33 per cent) was 857 lb. per hour. The evaporation per pound of dry coal was 9.09 lb. of water from and at 212 deg. This is equivalent to 3.85 lb. of coal per boiler hp. and an efficiency of 64 per cent. The results obtained were therefore but slightly lower than those representing good practice in hand-fired power houses.

The typical Babcock & Wilcox waste-heat boiler for open-hearth furnace work is an 18-high cross-drum, usually with 16-ft. tubes, the gases being delivered to the fan through the horizontal circulating tubes. The fan, gears, and turbine are supported on a platform above the boiler carried on the boiler columns.

The majority of installations with open-hearth furnaces have been in mills already in operation, and oftentimes it has been no little problem to find a space large enough to install a boiler of the proper heating surface. The sectional design of the B. & W. boiler, however, has been of immeasurable advantage in such cases, for with this it is possible to modify the width, length, and sometimes the height to accomodate the local space conditions and thereby provide a sufficient and efficient heating surface.

The returns from such installations have been most gratifying. Not only has there been a return in steam sufficient to pay a handsome return on the investment, but in many of the plants there has been an increase of two heats a week from the open-hearth furnaces and this was accompanied, as one would expect, by an appreciable reduction in the coal per ton of steel. This reduction follows from a positive draft control.

Figures given during the war indicated a saving due to the installation of waste-heat boilers on open-hearth furnaces of from 25 to 30 cents per ton of steel produced. On the basis of 25 cents a ton, 50-ton heats, and 14 heats a week for 45 weeks, the annual saving would amount to $8400, while for a 100-ton furnace it would be $16,800. With a 100-ton furnace there would be offered a boiler of 550 hp., which at the period mentioned could be installed complete for approximately $50 per hp., or $27,500. On such a basis the installation would pay for itself well within two years. While the saving expressed in cents per ton of steel may not be as high today as the wartime saving given, nevertheless the ratio of saving to boiler cost would be approximately the same, since boiler costs closely follow steel costs.

In a certain waste-heat boiler installed over a reheating furnace at the Bethlehem Steel Works the gases and steel pass in opposite directions through the furnace and the former enter the boiler immediately above the gas-discharge end of the furnace. This boiler is 19-wide, 17-high, with 16-ft. tubes and 48-in. cross-drum, having 5830 sq. ft. of heating surface. Tests on this unit showed an average output of 540 hp. per hour with an entering gas temperature of 1445 deg. fahr., the gas exit temperature being 545 deg. The draft loss was approximately 1 in. water column. To overcome this loss and furnish sufficient draft for the proper operation of the furnace required approximately 8 boiler hp., or less than two per cent of the total generated by the boiler. Unfortunately, during these tests sufficient data were not obtained to show the relation of power developed to the steel reheated or the fuel consumed.

In a representative arrangement such as would be made with a malleable-iron furnace the boiler employed is 24-high, 3-pass, with longitudinal drums, the draft apparatus being located on a platform carried on the boiler columns. The unit is equipped with an auxiliary hand-fired furnace, which makes possible steam generation during such times as the malleable-iron furnace may be shut down. It is possible, however, to operate the boiler on both waste gases and gases from the hand-fired furnace, due to the fact that the draft required to operate the malleable furnace is about the same as that which would be required for hand firing.

Installations in Cement Mills

In 1915 a 1530-hp. Babcock & Wilcox boiler was installed for the Louisville Cement Company, this company being really the pioneer in the use of the modern design of waste-heat boiler in connection with cement kilns. Regarding the operation of this boiler, H. D. Baylor, superintendent of the company, in a paper presented before the American Institute of Chemical Engineers in June, 1917, said:

> Our coal consumption in the boiler room for 1914 averaged 91.7 lb. per barrel of cement. The waste-heat boiler was put into service during May, 1915, with the result that our average coal consumption for 1915 was 57.6 lb. per barrel of cement. During 1916 the boiler was operated practically full time and our average fuel in the boiler room for the year was 40.2 lb. per barrel.
>
> By using the hot clinker to heat the air for combustion and the waste kiln gases to generate steam, our percentage of heat utilized has almost doubled, showing 67.2 per cent fuel efficiency in the combined system of kilns and waste-heat boiler, and this we hope to increase to 70 per cent by reclaiming a part of the heat now lost by radiation from the kiln shell; and it is but another step to reclaim a part of the heat now escaping from the stack of the waste-heat boiler; or in other words, our combustion efficiency will eventually compare very favorably with general boiler-room efficiency.

In one more or less standard arrangement of waste-heat boilers, economizers, fans, collecting and connecting flues for cement-kiln work there is a common flue located transversely to the kilns into which they deliver the gases. On the opposite side of this flue the boilers are located, the gases passing through the short connecting flues. Between the kilns and the collecting flues as well as between the collecting flue and the boilers, water-cooled dampers are provided. The bottom of the flue is in reality a series of hoppers for depositing and handling the dust precipitated from the gases. These hoppers are provided with a slide valve and chute for discharging the dust to screw conveyors located beneath the main flue. The boilers, economizers and all short connecting flues are also provided with hoppers similarly equipped with slide valves and chutes. Ordinarily the main flue and all connecting flues are made of steel plate lined with insulating material and firebrick.

An arrangement of this kind lends itself to flexibility in that any boiler or kilns may be taken off without interruption of the

plant output, since the boilers are so designed, when there are three or more, that one boiler may be taken out of service and the remaining boilers handle all of the gases. When an installation of only two boilers is made it is not practicable, from the standpoint of cost, to have each unit of sufficient size to handle the total weight of gas, should it be necessary to take one unit off the line. A two-unit installation is therefore not as flexible as one with a greater number of boilers, and with one unit down, the remaining unit, while capable of handling more than half the total gas, would probably not handle more than 75 per cent of the total, necessitating the by-passing of the remaining gas to the atmosphere.

The economizer employed is of the counterflow type. The tubes are inclined horizontally, extending transversely to the boiler tubes, a recent development of the Babcock & Wilcox Co. and desirable for its compactness. The gases pass downward over the heating surface, thereby reducing the tendency of dust to settle and lodge on top of the tubes. The water flows upward, thereby avoiding pockets should any steam be formed in the economizer.

These boilers and economizers are provided with a type of soot blower which, if properly operated and properly cared for, will keep the gas passages entirely free from dust lodging, so that it hardly becomes necessary to shut down a boiler for external cleaning.

The fan location is at the floor line and a steel stack is carried on the fan housing. The stack should be of sufficient height to relieve the fan of labor in discharging the gases. It should also be of sufficient height to guard against the gases entering adjoining buildings as they leave the stack.

Some interesting figures are given by the Southwestern Portland Cement Company, in whose plant there are three Babcock & Wilcox units installed. Each unit consists of 7560 sq. ft. of boiler heating surface, 720 sq. ft. of superheating surface, 3750 sq. ft. of economizer surface, and a steel-plate fan capable of handling 120,000 lb. of gas under a pressure of $6^3/_4$ in. water column. These three units are connected to three kilns 150 ft. long by 8 ft. in diameter.

During October and November, 1920, this company generated an average of 1,029,900 kw-hr. per month while burning 52,032 bbl. of clinker. To generate this power they burned an average of 2409 tons of coal under coal-fired boilers, or at the rate of 4.68 lb. per kw-hr. During February and March, 1921, after the waste-heat boilers had been in operation 60 days, they developed an average of 1,200,791 kw-hr. per month while burning 64,109 bbl. of clinker. To generate this 1,200,791 kw-hr. they burned an average of 554 tons of coal under the direct-fired boilers, which was equivalent to 0.95 lb. coal per kw-hr. This shows a saving of 3.73 lb. of coal per kw-hr. or 80 per cent, and a saving of 69.8 lb. of coal, for power purposes, per barrel of clinker burned.

UTILIZATION OF WASTE HEAT IN THE STEEL INDUSTRY

By A. T. LEWIS,[1] BETHLEHEM, PA.

THE steel plant has made wonderful progress in new developments in the last decade, but it is only in recent years that utilization of waste heat has been given much thought.

The prime object in the steel industry has been the development of the material desired without much consideration of how it was to be done. Furthermore the location of the steel industry had been in sections where the raw materials were plentiful, with the result that economy of materials was apparently not very essential. But now, on account of greater competition and the high climbing costs of materials, the steel industry is being forced to give closer attention to economies. This is resulting in the greater utilization of waste heat.

The operations of the steel industry are such that very large quantities of heat are necessary to perform the desired work. Only a small part is being converted into useful work, which leaves a large per cent of energy in the form of waste heat.

Blast Furnaces

Most steel plants are equipped with blast furnaces, open-hearth furnaces, mills, forge and machine shops, power plants and buildings, and they are usually so grouped that the utilization of heat in any branch can be converted into work of benefit to the other departments.

In blast-furnace work the gas was considered a waste product a short time back, and still in many furnaces this valuable fuel is bled to the atmosphere. Even in many modern blast-furnace plants a great improvement can be accomplished in its better utilization. This gas is primarily used for stoves, blowing and power engines, boilers and miscellaneous heating. With properly designed equipment and proper control the maximum economy should be obtained, and the quantities are so large that such economy would spell great savings.

A blast-furnace heat balance shows that approximately 40 per cent of the heat available in the furnace is used in its own operation. This includes preheating of the air and the losses carried away from the furnace and leaves 60 per cent available for other useful work, such as power units, boilers and miscellaneous heating. To realize the importance of the proper utilization of this waste gas an approximate heat balance of a 500-ton blast furnace is given in Table 1.

TABLE 1 APPROXIMATE HEAT BALANCE OF A 500-TON BLAST FURNACE

Total available gas leaving the furnace, cu. ft. per ton iron	128,000
Net heat value of cold gas, B.t.u.	95
Coke rate, lb. per ton	1,917
Air displacement per ton at blowing engines, cu. ft.	116,000
Air heated at stoves per ton (from 160 deg. fahr. to 1115 deg. fahr.) cu. ft.	110,000
Stove efficiency, per cent	60.0
Required by stoves, per cent	32.4
Required by blowing engines, per cent (26 per cent thermal efficiency per air hp.)	8.4
Required by power engines, per cent (23 per cent thermal efficiency per kw.)	21.6
Available for boilers, per cent	37.6
	100.0
Cu. ft. gas per lb. net coke	70
Cu. ft. air to stove per lb. coke	66

Since large quantities of material are dealt with, the steel plants are giving closer attention to the proper use of this gas than they ever did. Beyond the present development of efficient burning of the gases in stoves, boilers and gas engines there is a further development that can be placed to good use, namely, the utilization of the waste heat in gas engines. This will be dwelt on later.

Open-Hearth Furnaces

A steel plant is not complete without a series of open-hearth furnaces. The highest temperature that can be obtained from fuel is desired in the refining of steel. For this process a relatively small percentage of the available heat of the fuel is abstracted, which leaves a very high percentage to pass out from the furnace. A small part of this heat leaving the furnace is recovered in the preheating of the incoming air and gas. In a 70-ton open-hearth furnace from 70,000 to 100,000 lb. of gas normally enters the stack per hour at a temperature of from 1000 to 1200 deg. fahr., and this heat should be utilized. The steel mill usually requires a large generation of steam. The utilization of this heat by means of waste-heat boilers is a means of reducing considerably the total steam-generating costs.

The fuel usually employed is producer gas, unless coke-oven or natural gases—of higher calorific value—are available. In order to develop the necessary temperature and also to effect economy of fuel the air for combustion is preheated before entering the furnace. Where the more sluggish producer gas is used, it is also preheated, which enables it to ignite more readily than when cold. When coke-oven or natural gas are used they are introduced into the furnace without preheating because they are high in hydrocarbons which disintegrate at temperatures above 1000 deg. fahr., thereby causing great fuel loss. In the average open-hearth furnace it will be well to note that of the heat absorbed and the heat that is available for waste heat development—

18 per cent is abstracted for useful work
3 per cent is lost in the sensible heat of the slag
40 per cent is lost in the sensible heat of the stack gases, and
39 per cent represents other losses such as radiation, etc.

The largest item is the heat lost to the stack, and in many furnaces this amounts to more than 50 per cent. To reduce it the

---

[1] Bethlehem Steel Co.

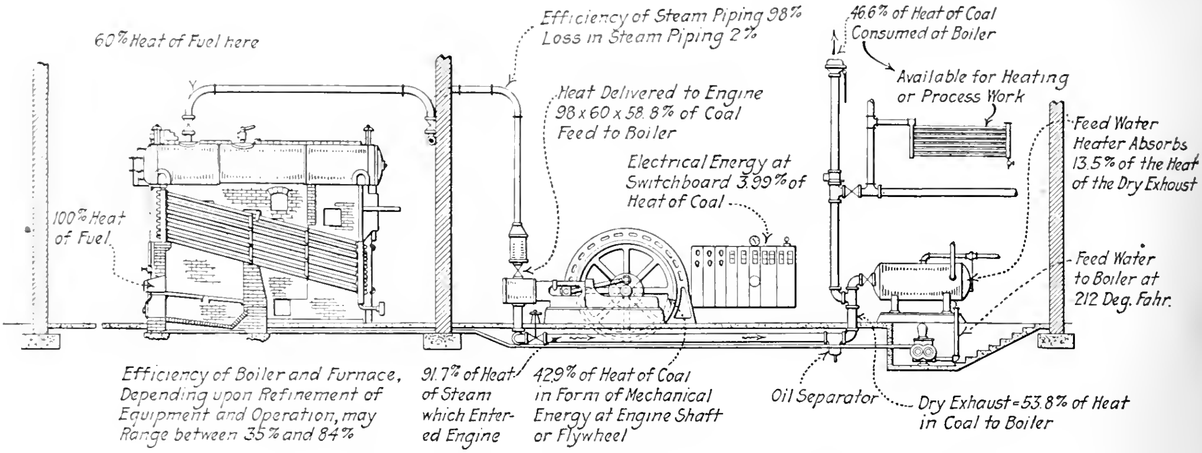

Fig. 1 Typical Power-Plant Installation with Simple Engine Direct-Connected to Generator

steel plants have resorted to waste-heat boilers by means of which about fifty per cent of the loss can be converted into steam. Furnace gases normally enter the boiler at from 1000 to 1200 deg. fahr. and are reduced to a temperature of from 450 to 550 deg. fahr. before leaving. A well-designed boiler equipment with necessary flues is an asset in the operation of a furnace, since the draft may be regulated by the fan speed at the will of the furnace operator. Furthermore, the value of this abstracted heat is equivalent to 60 boiler hp. per ton of steel. This is equivalent to at least 350 boiler hp. per furnace of about 70 tons capacity and is valued at $3.50 per hour, using anthracite steam coal at $3 per ton as a basis for calculation. It amounts to $2500 a year per furnace and is the best way of recovering heat energy that would otherwise be lost at certain times in metallurgical processes.

Mill heating furnaces have a lower exit temperature than open-hearth furnaces, and if the proper state of combustion is maintained and the furnace is designed correctly a higher thermal efficiency should result. The exit temperatures of mill furnaces vary from 850 to 2000 deg. fahr. and the quantity of heat generated is dependent upon the capacity of the furnace. A waste-heat boiler installation on such furnaces makes an ideal layout and fits in nicely with the steel-mill boiler plant. Table 2 shows a typical heat balance of an open-hearth furnace including waste-heat boiler.

Gas versus Steam Power

Modern steel plants that have blast furnaces are usually equipped with gas-engine installations. Gas engines have shown marked improvement in recent years and are employed on account of the low total cost of operation, which is particularly true in the blowing units. This is caused by their relatively high efficiency when compared to steam units.

TABLE 2 TYPICAL HEAT BALANCE OF AN OPEN-HEARTH FURNACE INCLUDING WASTE-HEAT BOILER[1]

	B.t.u. per hour	B.t.u. per ton ingots	Per cent of heat in coal	Per cent of heat in fuel gas	Per cent of heat to furnace
Coal to gas producers....	52,500,000	7,000,000	100.0		
Producer loss............	8,610,000	1,150,000	16.4		
Heat Delivered to Furnace:					
Gas from producers....	43,890,000	5,850,000	83.6	100.0	
Combustion of C, Si, and Mn in charge......	9,370,000	1,250,000	17.8	21.4

[1] Results based on the following empirical data:

Size of heats, tons	75
Time per heat, hours	10
Hot metal in charge, per cent	64
Ratio of product to charge, per cent	88
Fuel consumption (4875 lb. per hr. or) lb. per ton	650
Heat value of coal, B.t.u. per lb.	10700
Weight waste gases at boiler, lb. per hour	81400
CO_2 in waste gases at boiler, per cent	12
Temperature of waste gases at boiler inlet, deg. fahr.	1200
Temperature of waste gases to stack, deg. fahr.	500
Performance of boiler under above conditions, boiler hp.	460

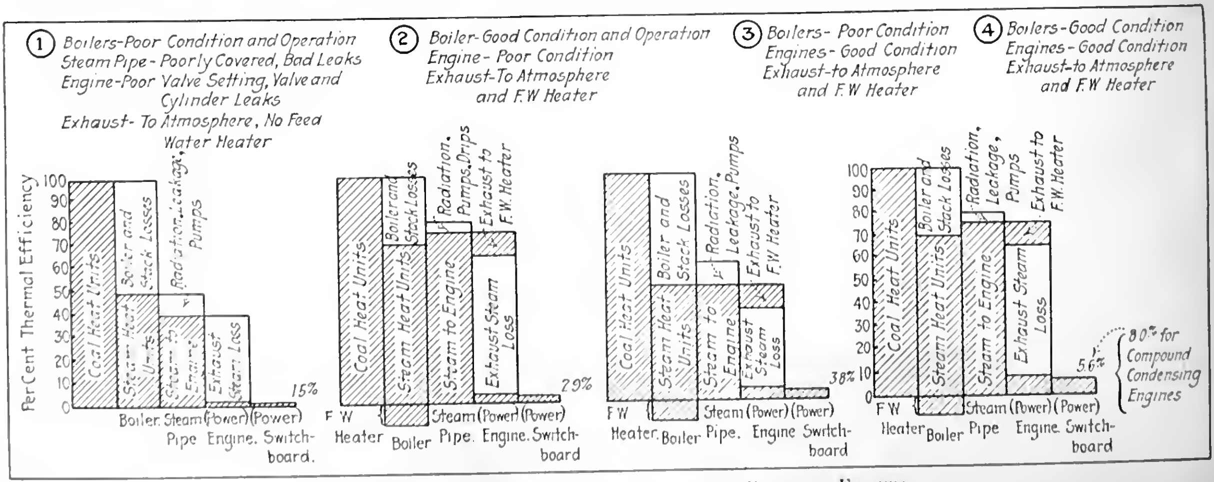

Fig. 2 Approximate Heat Balance, Simple and Compound Engines

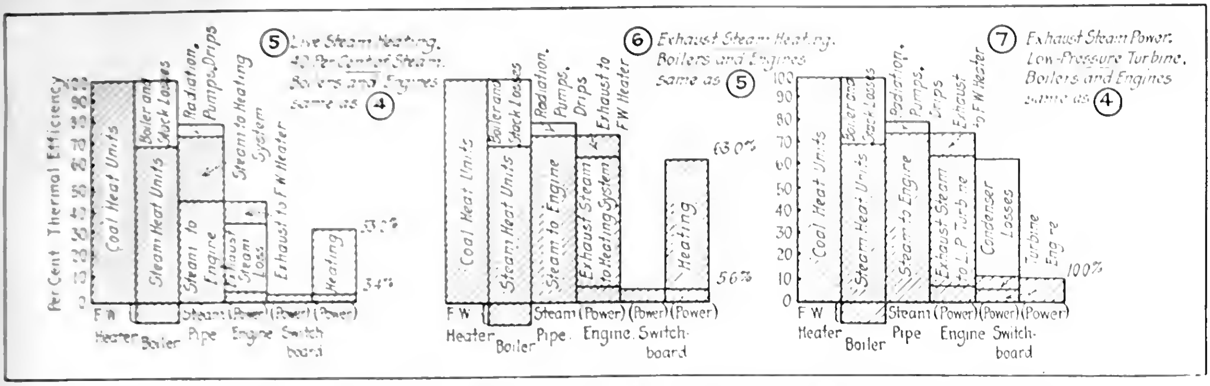

Fig. 3 Approximate Heat Balance, Simple Engines and Turbines, Exhaust Steam Used for Heating

It will be well to consider the percentage heat balance of a gas engine and compare it to that of a steam engine as follows:

	Gas engine	Steam engine
Effective work	28	11
Friction in engine	5	2
Exhaust gases	36	
Exhaust steam		57
Cooling water and radiation	31	
Boiler loss	..	30
	100	100

The total gas-engine efficiency can be raised to above 60 per cent, which establishes it as a most economical thermal unit. The development of waste-heat utilization in gas-engine installations should create a greater demand for this type of prime mover in the future, and it will show up to better advantage as the price of fuels increase. A very high efficiency is readily obtained by installing waste-heat boilers or economizers in the gas-engine exhaust and utilizing the jacket water either for feedwater, heating buildings, or any other scheme that will fit into plant conditions.

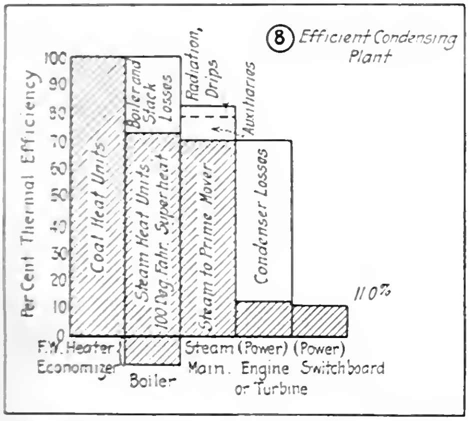

Fig. 4 Approximate Heat Balance of Large Power Station, Condensing Plant

In the steel industry, before the product is finished it goes through many processes where mechanical work has to be performed. This is usually done by steam units such as mill engines, steam hammers, steam pumps, etc. These types of units perform their necessary work very well mechanically, but thermally they are very inefficient. Since they perform their work satisfactorily it is necessary that some means be employed to reduce the cost of operation of such units by converting this very high thermal loss into useful work. To realize the effective work performed by such similar units it is well to examine a few sketches. Fig. 1 shows a diagrammatic heat balance of a typical power-plant installation where the power is derived through a simple engine. This diagram shows the heat extracted from the coal to do its necessary work in the engine and the heat available in the exhaust steam, and indicates the manner in which this exhaust steam can be utilized. Carefully note that in this case 91.7 per cent heat of the steam is available in heat energy after it has done its necessary work in the engine. Further utilization can be effected by the means as shown in the diagram.

Figs. 2, 3 and 4 give approximate heat balances of various steam-consuming units and indicate the available steam beyond the direct consuming unit to be used for other purposes.

It is such units as shown by the heat balances that the steel industry has to contend with. In the warm months of the year exhaust steam is usually not required for heating purposes, but it can be utilized to great advantage if introduced into low-pressure turbines.

UTILIZATION OF WASTE HEAT FROM ROTARY CEMENT KILNS

By JOSEPH BROBSTON,[1] NAZARETH, PA.

In America, portland cement is burned exclusively in what is known as a rotary kiln. This is strictly an American development. It has always been known that it was not an economical method of burning, but as coal was cheap and labor high in America, it was universally adopted immediately after its introduction, whereas in Europe where coal was dear and labor cheap, the old style upright kiln similar to a lime kiln held its own up to within a few years.

While the largest loss of heat in the rotary kiln was in the excessive temperatures of the flue gases, there were two other important heat losses which were at that time attracting attention, one being the heat carried off by the material or resulting clinker, when it was discharged from the kiln; the other being the loss by radiation through the kiln shell.

There was one notably successful attempt made to utilize a part of the heat of the flue gases. In the dry process of cement manufacture it is necessary to dry the raw material before it can be pulverized. Charles Matcham put his stone dryers immediately back of his kilns, and passed a portion of his kiln gases through them. This did not affect the operation of his kilns, dried the stone more effectively, saved about three to four pounds of coal per barrel of cement made and materially reduced the labor charge in connection with the drying. Only a small percentage of the total stack gases were required for this, however, and there were not many of the installations made.

The sporadic efforts made to use the waste heat of rotary kilns prior to the sudden and material increase in the price of coal caused by the war, did not amount to more because of the very low price that the industry as a whole paid for its kiln coal. The coal generally used is the slack or screenings from $^3/_4$ gas coal. This was formerly considered a waste product by the coal mines and had to be moved when the $^3/_4$ coal was shipped, which resulted in a price to the cement industry ranging from 20 to 75 cents a ton at the mines. The cost per barrel for burning cement was therefore comparatively low and the efforts of the

---

[1] Vice-President, Dexter Portland Cement Co. Mem. Am.Soc.M.E.

manufacturers were mainly directed to installing labor-saving machinery and reducing the cost of pulverizing the raw material and clinker.

When the price of coal jumped to $5 per ton at the mines, however, conditions were entirely different, and in 1915 the first modern waste-heat boiler plant in the cement industry was installed at the Catskill plant of the Alpha Portland Cement Company. This installation was a success from the start. The plant operates five kilns, three being 9 ft. in diameter by 120 ft. long and the other two 7 ft. 6 in. in diameter and 120 ft. in length, resulting in an output of about 3000 bbl. of cement per day. The gases from these kilns are drawn into a main or equalizing flue directly in the rear of the kiln housing or dust chamber, dampers being installed to by-pass gases into the kiln stacks, if necessary. Connections leading from the back of this flue conduct the gases to two 750-hp. Edge Moor boilers, of the four-pass type. Two Green fuel economizers, horizontal type, are installed after the boilers. The forced draft is provided by a fan located directly back of the economizers, driven by a Terry turbine. A steam pressure of 175 to 180 lb. is maintained, and sufficient power is generated to operate the entire plant. The finely pulverized stone carried over from the kiln by the hot gases is blown from the boiler tubes three to four times in each 24 hours, a hand lance using 140 lb. of air being employed for this purpose. The economizer tubes are blown off through plugged openings in the top of the casing several times each week. The clean-out doors at the bottom of each pass are opened once a week and the dust removed. Clean-out doors are also provided in the flues. In this way, if the draft at the stack chamber is not allowed to drop below 0.25 in. (water pressure), no real difficulty is experienced in keeping the installation free from dust. The temperature of the gases is reduced from approximately 1400 deg. fahr. at the mouth of the kiln to about 450 deg. when they leave the economizer. The Cochran feedwater heater is heated by the exhaust steam from the pumps and fan turbine. The operation of the boilers has not increased the amount of coal used per barrel in the kilns. It is about 95 lb. per bbl. It requires not less than 40 lb. of coal per bbl. to generate the power required to operate a cement mill. Deducting this from the 95 lb. being used in the kiln we find that today this company is burning their cement with 55 lb. of coal, which is much closer to the theoretical amount required, that is, 30 lb., than the cement manufacturers had ever hoped to come, and means that a rotary kiln with a waste-heat boiler attached is as economical in its coal consumption as the old-style upright kiln. Plants almost exactly duplicating the one described were promptly installed at another plant of the Alpha Portland Cement Company and at the Dexter Portland Cement Company, and plants using B. & W. boilers were installed by the Universal and Louisville cement plants.

By this time all the manufacturers of portland cement were aware of the importance of this development, and the Conservation Committee of the Portland Cement Association, started an extensive investigation of the entire question. The first report presented in December, 1918, showed eight plants in operation. Today there are 24 plants in operation generating with their flue gases from 51 to 140 per cent of the power they require. There are about 120 operating portland-cement plants in the United States, so that 20 per cent of the plants are now making use of their stack gases, saving on the average 40 lb. of coal for every barrel made. This means that these companies are actually using about 400,000 tons of coal less per year than they did formerly.

It may be noted that in some cases more steam than is required to operate the entire cement plant is generated by the waste-heat installation. In other cases only a little over one-half of the amount required is secured.

While this is to a certain extent a question of the efficiency of the boiler installation, it may be due to other causes. The plant that is burning cement with 80 lb. of coal to the barrel will not have the volume of stack gases or temperature that will be found at the plant using over 100 lb. to the barrel, so that naturally not as much steam can be generated. The total amount of coal used per barrel, however, may be lower at the plant using the 80 lb., as it may be possible to generate the additional power required in auxiliary boilers with less than the extra 25 or 30 lb. of coal consumed in the kiln.

But even when two waste-heat plants generate the same amount of steam, there may be a great difference in the percentage of the machinery that can be run with it. Where the amount of steam secured is just sufficient to operate a mill in which the prime movers are well-designed modern turbines, it would probably be only 75 per cent of the steam required to operate another plant which is still being run with old-style inefficient reciprocating engines.

Power Required to Grind a Barrel of Cement

Where the prime movers are identical, there might still be a wide difference in the percentage shown. Recent investigations made by the Conservation Committee of the Portland Cement Association show that the power required to produce a barrel of cement at plants using different types of grinding machinery varies from about 13 kw-hr. per bbl. to about 19 kw-hr.

Some progress has also been made in the last three or four years in solving two other problems. The loss through radiation is being materially reduced by putting between the shell and the firebrick lining in the upper part of the kiln, a brick cut from diatomaceous earth. While it has not been possible to determine the exact amount saved in this way, it has been shown conclusively that where waste-heat boilers are being used this insulation raises the temperature of the flue gases 150 deg., and where boilers are not installed the insulated kilns require from 5 to 10 lb. per bbl. less coal to burn clinker than those not insulated.

This problem is not as yet fully solved, however, as it has been found impossible to use the insulating brick in the hottest section of the kiln, known as the burning zone. Here the fluxing action of the clinker at the high temperature necessarily maintained was such that the firebrick were practically destroyed in from 16 hr. to four days. The hot zone can undoubtedly be insulated by using carborundum, but at the present time the cost of doing this would be prohibitive.

The Technical Problems and Conservation Committees of the Portland Cement Association are working on this problem with the firebrick manufacturers and it is hoped that a suitable block that will stand up and which can be made at a reasonable price, will be developed.

Possibility of Reclaiming Heat Carried off by Clinker

As to the possibility of reclaiming the heat carried off by the clinker, the development of the rotary pressure cooler in the last few years has demonstrated that where the cooler is of sufficient size and proper design to handle the kiln output it is possible to heat the air entering the kiln to a temperature of 800 to 900 deg. fahr. and to have enough heat left over to dry the coal used for kiln operation. How much this saves is problematical. So far the power required to operate the system has been found to be so great that there appears to be very little actual saving.

In the ideal cement plant of the future there should be no wasted heat. Where the engine room is equipped with the modern economical type of prime mover, and the mill has been designed and equipped with grinding machinery that requires the minimum amount of power, the stack gases will generate not only sufficient steam to run the plant and heat the buildings, but there will be enough left over to dry the stone. All the heat will be drawn from the clinker and it will be sufficient to raise the temperature of the air required to support combustion in the kilns to a point that will materially reduce the amount of coal needed for burning, and there will be enough left over to dry the coal before it is pulverized.

With the preheating of the air and the insulating of the balance of the kiln, the amount of coal required to burn should certainly not be over 75 lb. to the barrel. Deducting from this the 40 lb. required for power, the 3 lb. required for drying the stone and 1 lb. each for drying the coal and heating the buildings, the theoretical figure of coal required to burn a barrel of cement is reached, namely, 30 lb. per bbl.

While this ideal may never actually be attained, the work on all three problems has progressed far enough to show that within the next five years through the insulation of kilns, the preheating of the air going to the kilns, and the use of stack gases, there will be saved in producing 100,000,000 bbl. of portland cement, besides the 400,000 tons already mentioned, about 1,600,000 tons, or a total of 2,000,000 tons due to the utilization of waste heat.

Paint Protection for Wood

By CORNELIUS T. MYERS,[1] RAHWAY, N. J.

About two years ago the writer, in carrying on some research work on wood wheels had occasion to make inquiry among paint manufacturers as to the value of various kinds of paints and primers for the protection of wood against moisture. This inquiry brought out so many differences and variations in opinion as to paint materials and mixture proportions that a more extensive inquiry among paint men was started. This inquiry revealed that:

1. (1) There was comparatively little technical information to be gained from the paint industry on the relative protective values of different coatings for wood
2. (2) The paint industry did not generally recognize the moisture-proofing of wood as a problem, but was concentrating so far as the more reputable manufacturers were concerned on producing paints that would last as long as possible on the surface to which they were applied. In other words, such improvements as have been made have contributed to the life of the coating rather than the life and usefulness of the article which received the coat.

As the demand upon our forests depends to a very considerable extent upon the life of forest products, and as the life of these products in many cases depends to a very considerable extent upon the protection against moisture they receive, the intimate knowledge of protective coatings is a factor of great importance in our lumber conservation program; to say nothing of the possible saving in our $300,000,000 annual paint bill. Wood in its natural green condition has a very limited use as a structural material. Its tiny fibres are cellular in form and contain a large amount of moisture, commonly known as sap, the sap being water containing very small percentages of tannins, sugars, gums and coloring matters. To give wood the physical qualities which make it fit for use in buildings, furniture, truck bodies, wheels, etc., it is necessary to remove most of the moisture.

Moisture in Wood

Wood is said to be oven-dry when continued oven drying causes no further loss of weight. In their green state the woods used structurally have a moisture content of 60 to 120 per cent of their oven-dry weight, and weigh roughly from 60 to 120 per cent more than when they are in an oven-dry state. In other words, 35 to 55 per cent of the weight of a green log is water. In the green log this water exists in two conditions:

1. (1) Minute particles of water in each tiny wood cell cavity, known as "free water"
2. (2) The moisture absorbed by the fibrous material which forms the walls of the cells, known as "hygroscopic moisture."

Felled wood exposed to average atmospheric conditions gradually dries, the air taking up its moisture. First the cell cavities slowly give up their moisture. This evaporation goes on until the cell cavities are emptied of the minute particles of "free water" they contain. All that remains is the moisture actually absorbed by the fibres of the cell walls, which are still saturated with the "hygroscopic moisture." Wood in this state is said to be at its "fibre-saturation point." Up to this time the wood does not appreciably change in size or in physical characteristics except as to weight, which of course decreases considerably as it will now contain but 25 to 30 per cent of moisture instead of 60 to 120 per cent.

Further drying of the wood is necessary in order to increase its strength and hardness, increase its durability, enable it to take and hold paint, and in general to improve its condition for the purpose intended. As this drying progresses beyond the fibre-saturation point, the cell walls give up the moisture they have absorbed, and in so doing they shrink and harden. Under natural conditions this drying process will continue until the amount of moisture in the wood bears a quite definite relation to the average humidity condition in the particular locality. (See Fig. 1.) In the eastern and north central states, for instance, the moisture content of wood will become stabilized somewhere in the neighborhood of 14 per cent for what is known as thoroughly air-dried stock. In the arid, southwestern states it will contain a still lower percentage, while in the former war zone of France the wood will normally contain considerably more than 14 per cent of moisture. Of course unpainted wood that is exposed to rain and snow will absorb considerably more than 14 per cent, depending upon the dimensions of the piece and the extent of the exposure.

Data secured from the Forest Products Laboratory of the United States Department of Agriculture show that

1. (1) Many woods should be dried to about 8 per cent moisture content to give the best results as to strength, durability, hardness and finish (See Table I)
2. (2) It is also true that if after being dried, and shrinking in the process, wood reabsorbs moisture, it will swell again according to the amount absorbed
3. (3) The shrinking and swelling along the grain, perpendicular to the grain and tangential to the grain all differ, and very materially, for a given change in moisture content. (See Table 2.)

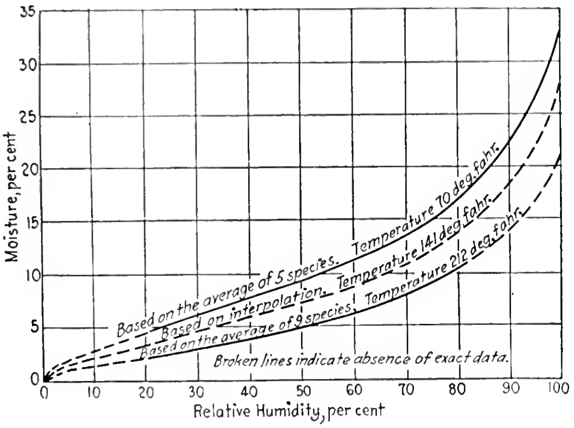

Fig. 1 Relation between the Amount of Moisture Absorbed by Wood and the Average Relative Humidity

From the two following tables it will be seen that it is quite

TABLE 1 APPROXIMATE PERCENTAGE OF INCREASE IN STRENGTH OVER GREEN[1]

	Dried to 14 Per Cent Moisture	Dried to 8 Per Cent Moisture
Bending strength, modulus of rupture	40 to 60	80 to 100
Compressioo parellel to grain	80 to 90	100 to 150
Compression perpendicular to grain	65 to 75	
Stiffness, modulus of elasticity	20 to 30	25 to 35[2]
Hardness	30 to 35	40 to 50[2]
Shearing strength, parallel to grain	40 to 50	60 to 70[2]

[1] Compiled from Data given in Timber, Its Strength, Seasoning and Grading by H. S. Betts.

[2] Estimated.

TABLE 2 SHRINKAGE AND MOISTURE CONTENT OF HARDWOOD[1]

	Specific Gravity of Dry Wood	Shrinkage[2] in Per Cent of Green from Green to Oven-Dry		Green Moist in Per Cent of Dry Wood Wt.
		Radial	Tangential	
Ash, white[3]	0.57	4.8	7.0	39
Birch, yellow[3]	0.55	7.4	8.9	68
Elm, cork	0.57	4.8	8.1	53
Hickory[4]	0.64	7.2	10.9	60
Maple[5]	0.51	4.2	8.5	63
Oak, red[5]	0.56	3.9	8.3	83
Oak, white[5]	0.60	5.3	8.8	66
Average	0.57	5.4	8.6	62

[1] Compiled from data given in Kiln Drying of Lumber by H. D. Tiemann

[2] Average shrinkage along the grain, up and down as the tree grows, is only about ½ per cent.

[4] Average of 9 species

[5] Average of 3 species

---

[1] Consulting Engineer. Mem. Am.Soc.M.E.

desirable to have wood thoroughly dried, and that steps should be taken to keep it so. But although it is easy to reduce the moisture to 8 per cent in dry kilns, it is difficult to maintain the wood at this point: because of unsuitable protective coatings, or processes, and because of the lack of knowledge as to relative ability of various coatings for really stabilizing the moisture content within a small range.

Protectiveness of Paint

While we know that several coats of good paint may give adequate protection for floors, truck bodies, furniture, wheels or other wooden articles, we by no means know what paints give the best protection or what paints will give fairly satisfactory protection for the least money. The test fences, where many different paints were exposed to the same atmospheric conditions, have given some data on the durability of paints, but very little data on the durability of the painted article or its dimensional stability. *In durability and dimensional stabilization we are greatly interested;* in the first for very obvious reasons, in the second because wooden structures, furniture, etc., are more durable, serviceable, and can be made more simply if their various component parts do not expand and contract with changing wheather conditions. The cost of drying could be reduced in many cases, if when dried to a certain point the moisture content could be stabilized. Wood, on account of its very valuable characteristics, could be used in places where metal now seems necessary. A dozen or more prominent concerns in the paint industry have been coöperating very commendably in this research work, realizing that the dimensional stabilization of wood by moisture-proofing was a proper function of paint and of world wide importance. There is, however, quite a difference of opinion among these manufacturers as to what materials should be used, and how they should be mixed and applied. During the war the Forest Products Laboratory investigated the moisture-proofing effects of linseed oil and various paints, varnishes and leaf-metal coatings as applied to airplane-propellers and other airplane parts made of wood, but this work has not been broadened because of lack of funds.

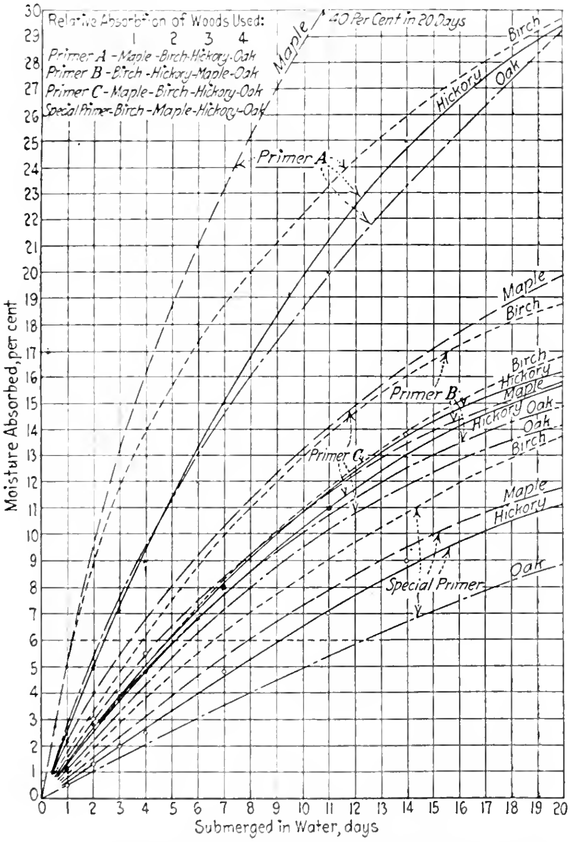

Fig. 2 Curves Showing How the Effectiveness of Different Primers as Moisture-Proofing Agents Varied for Different Woods

In order to get some comparative data on the paints and primers now on the market, the following schedule was drawn up by the writer, and tests were made on small pieces, measuring 1 × 1 × 1 in., of hickory, oak, birch and maple by several well known paint concerns:

(1) Dry slowly and completely until pieces cease to lose weight
(2) Determine "oven dry" weight
(3) Allow reabsorption to 8 per cent
(4) First coating to be applied at 8 per cent moisture content
(5) Second coating to be applied at 8 per cent moisture content
(6) Third coating to be applied at 8 per cent moisture content
Note: 24 hrs. to elapse between 4 and 5, and 5 and 6.
(7) Allow the three coatings to dry for a week under conditions of 70 to 80 deg. fahr. temperature, 40 per cent relative humidity, under which condition the moisture content of the wood should remain at 8 per cent even if the wood had no protective coating
(8) Label and weigh for base weight at 8 per cent moisture content with protective coating
(9) Submerge in water at 70 deg. fahr.
(10) Weigh every 24 hr. for first week, every 48 hr. thereafter and determine percentage of increase in moisture
Note: *Please bear in mind, of course,* that whatever is used in the way of coatings, it must serve as a suitable foundation for subsequent coats of paint and varnish.

In general, the results of the tests showed that paints of the ordinary brands and formulas were not very effective as moisture-proofing agents, even when three coats were applied. One paint concern after testing its standard brands, did a little experimenting, and without much difficulty was able to produce a special primer that was several times as effective. The curves in Fig. 2 show quite emphatically the variation in effectiveness of the paints used. Averaging the results for hickory, oak, maple and birch, it took about six times as long for these test pieces to absorb an extra 6 per cent of moisture when coated with the "special" as when coated with the standard "A." There is every reason to believe that much better results can be secured and with less than three coats. Preliminary tests with a casein solution indicate that it has waterproofing qualities, which, for some classes of protection, may be very valuable. The same is true of some of the pyroxalin compounds. Varnishes are in general more effective than paints, but in the protection of wheels its application was not suitable for primary coats.

Need for Research

What has been said so far shows the need for research work on this subject. Cabinet and furniture makers are vitally interested in a coating which will prevent wood from "working," shrinking and swelling, due to atmospheric changes in winter and summer. Interior woodwork could be greatly simplified if the dimensions of each particular piece of wood remained the same or varied but a very small amount. Flooring, decking, paneling, etc., would be greatly benefited if it did not "work." Many wooden structures would be simpler and more permanent if so protected, and with thoroughly dried timber they would either have a greater factor of safety or could be built with less lumber. Many other advantages will develop as thought is given to this subject—*The Dimensional Stabilization of Wood by Rendering it Moisture-Proof to Some Substantial degree.*

It is well known that shingles and weather boards fastened with old fashioned wrought-iron nails stay tight much longer than those in which the modern steel nail is used. The reason for this is that the steel nail rusts and is flaked off by the movement, or "working," of the piece through which it is driven. A nail tightly driven is practically sealed against external moisture by its head and the paint around it; but if moisture reaches the nail by the capillary action of the wood fibers, it will rust in spite of end sealing. Then too the moisture and capillarity of the wood cause the "working"

Welding Session Develops Salient Facts

Gathering Under Auspices of American Welding Society and A.S.M.E. Boiler Code Committee at Atlanta Meeting Emphasized Problems to be Met in Advancing Art of Welding

THE search for dependable information about the strength of welded pressure vessels which the A.S.M.E. Boiler Code Committee has been conducting for the past few years resulted in an exceedingly interesting session at the Atlanta Spring Meeting of The American Society of Mechanical Engineers on May 11, 1922. The session was arranged jointly by the American Welding Society and the A.S.M.E. Boiler Code Committee and was presided over by E. R. Fish, Chairman of the A.S.M.E. Boiler Code Sub-Committee on Air Tanks and Pressure Vessels.

Four papers were presented at the session, namely: Strength of Electrically Welded Pressure Containers, by R. J. Roark, Madison, Wis., assistant professor of mechanics, University of Wisconsin; Some Principles of the Construction of Unfired Pressure Vessels, by S. W. Miller, proprietor of the Rochester Welding Works, Rochester, N. Y.; Steel for Forge Welding, by Frank N. Speller, metallurgical engineer, National Tube Co., Pittsburgh, Pa.; and Tests on Welded Cylinders, by E. A. Fessenden, professor of mechanical engineering, Rensselaer Polytechnic Institute and L. J. Bradford, assistant professor machine design, Pennsylvania State College. Professor Roark's paper, slightly abridged, appeared in the April issue of MECHANICAL ENGINEERING, Mr. Miller's in the June issue, and Mr. Speller's in the July issue. The paper by Professors Fessenden and Bradford will be published in an early issue. These papers brought out a large amount of valuable discussion, both written and oral, liberal extracts from which immediately follow.

DISCUSSION OF PROFESSOR ROARK'S PAPER ON THE STRENGTH OF ELECTRICALLY WELDED PRESSURE CONTAINERS

S. W. Miller[1] wrote that the paper was very instructive in that it showed the inherent weakness of heads convex to the pressure. It should be noted that the nipple in specimen No. 1 was a source of weakness and that great care must be taken in designing pressure vessels to avoid such weakness.

In the case of the longitudinal seams failure occurred in all cases by breaking through the weld. Little was said about the kind of welding wire used, but the chemical analysis showed it to be low in carbon and manganese, and evidently it was much weaker in the weld than the plate, which was of high tensile strength, 64,000 lb. The carbon in the plate was given as 0.12 per cent, but it would hardly seem correct that a tensile strength of 64,000 lb. could be obtained with so low a carbon content. Also the carbon in the weld metal was given as 0.18 per cent, which was not possible with welding wire containing only 0.07 per cent carbon. Electric welds made with such wire contained 0.03 to 0.04 per cent carbon. This pointed to the necessity of careful sampling of weld metal. There was quite an interchange of carbon between the plate and the weld metal and no samples should be taken closer than 1/16 in. to the original line of the V.

With regard to the microphotographs shown, the magnification was not given but it was probably not over 100 ×, which was not sufficient to determine the structure of welds except in a general way. Electric welds made with bare wire were noticeably full of particles of ferrous oxide which required about 400× for their resolution.

The question of tests for welded containers was a very important one, and some means must be devised for so testing welded pressure vessels that such imperfect welds as had been described could not get into service. The danger did not arise from a steady pressure, but from alternating stresses or shocks which were liable to occur in any pressure vessel. Also temperature differences at times introduced unknown and unknowable stresses.

A large number of tests led him to believe that the tensile strength of thin films of such foreign matter as oxide in welds was of the order of 40,000 lb. per sq. in., but under shock combined with tensile stress rupture would occur at a much lower figure.

C. L. Jones[2] submitted a written discussion in which he said he was surprised to note that the low average tensile strength of electrically welded joints was given at 28,500 lb. per sq. in. and the shearing strength at 25,500 lb. per sq. in.

To show that the values were low Mr. Jones cited a number of similar tests, conducted along the same lines as shown by the author. One in particular was conducted on four arc-welded ammonia receivers 16-in. diameter, 1/4-in. plate material, by the York Manufacturing Company about two years ago, and reported in the 1921–1922 Proceedings of the American Welding Society by A. M. Candy. The welded joints were tested for brittleness by dropping a 10-lb. weight on them from a height of 10 ft. These blows, however, produced no visible effects on any of the joints. Following this the containers were tested to destruction.

Upon inspection it was observed that three of the tanks had been welded along the longitudinal seam while the seam rested in contact with a heavy backing strip of metal, possibly spaced 1/16 in. away from the actual joint. Furthermore, judging from the ruptured joints in the fourth tank the weld was made in at least three layers, which enabled the operator to obtain better fusion at the bottom of the joint with the first layer, and the latter layer improved the grain of the weld. These features readily explain the superiority of the fourth tank (70,400 lb. net) over the others (43,000–48,000 lb.) and illustrated the importance of proper welding procedure.

Numerous tests on pure arc-deposited metal cut entirely away from the plate steel upon which it was deposited have shown an ultimate tensile strength of 50,000 to 58,000 lb. per sq. in., and a shearing strength of from 38,000 to 42,000 lb. per sq. in. Further, the Wirt-Jones test of the Emergency Fleet Corporation reported arc welds of 36,300 to 66,480 lb. U. T. S. per square inch, made by a large number of different operators all over the United States.

He had personally witnessed many tests similar to one in discussion, and had never known of an average running lower than 30,000 lb. per sq. in., and did not recall any running lower than 35,000 lb. He believed that Mr. Miller's reports would show the lowest tensile strength of six specimens to be 39,330 lb. per sq. in., and the highest 45,600 lb.

As further assurance of his claims for higher average tensile strength of electric-arc welds he gave tables of tests, conducted by one of the largest railroads in the South, and one of the largest companies in the country manufacturing railroad and mine equipment. These welds were made under his own personal supervision, and the reports were obtained direct from officials of the companies mentioned. In neither of these tests did the ultimate tensile strength go lower than 35,230 lb. per sq. in., and in some of them it went as high as 76,000 lb. and did not break in the weld.

A. S. Kinsey,[3] discussing the low strength values given for the electric welds, said that they were obtained on single V welds on thin bars, and he believed that they were due in considerable degree to the eccentricity resulting from the large excess of thickness of the weld. If allowance was made for that in computing, the maximum stress would be seen to be about 42,000 lb. per sq. in. In any event the actual strength would be greater than this value, which was really not the strength of the material, but the strength of the wires. Strength, however, was not of so much significance as uniformity. The value of the nickel-steel welding rod was generally acknowledged and it was important that something should be done to standardize its nickel content, which should range from 3 to 3 1/4 per cent.

F. N. Speller[4] said that, taking the pressures at which the forge-welded and acetylene-welded cylinders failed and assuming the

fiber stress to be 50,000 lb., that being the fiber stress in the weld, the efficiency of the forge weld worked out at 80 per cent and that of the acetylene weld at 48 per cent. It therefore seemed to him that the proper place for acetylene welding on an important cylinder was on the girth seams, and that the longitudinal seams should be forge-welded.

Discussion of Mr. Miller's Paper on the Construction of Unfired Pressure Vessels

After presenting his paper Mr. Miller said that since writing it he had discovered a number of things which were of particular interest with reference to the quality of steel for welding.

In making tests on high-strength wires it was of course necessary to have high-strength plate, and ship plate had the highest tensile strength of any of the commercial plates, the upper specification limit being 68,000 lb. Its carbon content was usually about 0.25 per cent when $^1/_2$ in. thick. Some erratic results had led to a careful examination of some of the plate and of the welds made in it. The results of certain tensile-strength tests had shown a low value and rupture had taken place apparently along the line of the V. A careful microscopic examination showed that in some cases the rupture was parallel with the V at the defects in the base metal. In other cases a large amount of dirt had accumulated at or near the junction of the weld and base metal. These defects were both associated with non-metallic impurities in the plate, the latter being quite clearly so, and the former evidently so, though the connection was not so clear. In the former it seemed clear that at least some of the non-metallic impurities had been absorbed by the austenite when it had reached a temperature somewhat below that of melting. During the cooling and recrystallization these dissolved impurities were rejected to the γ-grain boundaries and became visible there as more or less continuous dark lines, or as spots of grayish matter having the appearance of ferrous oxide. When such a piece was bent and examined under the microscope, the rupture was found to occur at these visible defects.

Another defect which seemed to be of rather frequent occurrence is the accumulation at the bottom of the V of a large amount of ferrous oxide in the shape of minute gray dots and larger particles in size that range from 0.0005 to 0.015 in. in diameter, and sometimes larger. It was quite evident that these impurities were not in the wire as shown by a careful examination of it. Also they seldom appeared except at the bottom of the V.

When using wire that sparked freely, even with a neutral flame, it would be noticed that there were deposited on or near the work large quantities of small spherical particles which were mostly composed of magnetic iron oxide (Fe_3O_4), and which were frequently hollow, although occasionally in the larger ones their centers were filled with iron which had not had time to completely oxidize. These particles were of all sizes from the finest dust to several hundredths of an inch in diameter. They would easily stick to a surface that has been heated, and they actually did this, so that the V near where the torch was working was covered with them. They must be disposed of in some way during the welding, and it appeared quite clear that they might be dissolved in the melted metal, or washed down without having had time to dissolve and settle in the bottom of the V or close to the sides of the V. As most of these particles were very small, they usually escaped observation, and as in some cases they were very numerous, it was very probable that the welder was deceived by this coating melting instead of the metal itself, with the result of an imperfect weld. It seemed quite clear, therefore, that the quality of the base metal must be good if good results were expected, and that welding wire which sparked freely should be watched very carefully during welding. Also the size of wire and size of tip should be so related as to prevent sparking as much as possible.

In any plate impurities were usually found toward the center, which was natural as they occupied a similar position in the ingot. With a single V weld the washing of the melting welded rod naturally carried any impurities down with it toward the bottom of the V so that the weld, if imperfect, would be so toward the bottom of the V. This was almost invariably the case. It was equally true in a double V weld, but this had two advantages. First, the impurities had less surface to scatter over, and second, they were confined to the center of the plate, so that the weld, which was reinforced on both sides, tended to be equally as strong as the plate on account of the weld and plate sections being symmetrical.

J. H. Nead[5] wrote that the author had brought out in his paper the advantages of having the weld stronger than the plate and had stated that this could in general be accomplished in two ways: (1) By using ordinary plate and nickel-steel welding wire; (2) By using Armco ingot-iron plate and Armco ingot-iron welding wire. He believed, however, that all the inherent advantages of the latter method had not been brought out. In designing any structure which was subject to live loads, as most pressure vessels are, it was well to use a material which had a high resistance to fatigue. There had recently been published the report of an investigation on the fatigue of metals carried out by Prof. H. F. Moore of the University of Illinois, under the auspices of the National Research Council. (Bulletin No. 124 of the Engineering Experiment Station of the University of Illinois.) Professor Moore investigated many materials among which was Armco ingot iron and which he designated as 0.02 carbon steel. He found that this 0.02 carbon steel had a higher ratio of endurance limit to proportional limit than any other material. The endurance limit as he defined it was the maximum stress at which the material would withstand 100,000,000 reversals of stress without failure. In other words, that Armco ingot iron was an excellent material to resist fatigue. In the light of this information Mr. Nead believed that a safer pressure vessel could be constructed by the latter of the two above-mentioned methods than by the former.

In the Appendix B of Mr. Miller's paper was reported the performance of several welded pressure vessels under pressure test. The No. 5 tank shown on page 52 of the paper was returned to the American Rolling Mill Company by Mr. Miller after testing and two pieces, size 12 in. by 20 in. were cut out from the side of the tank, one from near each end. These were flattened out and four tensile test pieces cut from each. Two test pieces from each were tested without milling the welds off flush with the plate and two each were milled flush.

Three of the four unmilled specimens showed an average tensile strength of 51,100 lb. per sq. in. and broke in the plate rather than the weld. The fourth specimen broke in the weld (at 45,150 lb.), the fracture starting from a slight defect. In the case of the milled specimens the fracture occurred at the weld, as would be expected, but considerable ductility as indicated by the reduction of area was evident. The breaking load was approximately 48,000 lb. for three of the specimens, and 55,000 for the fourth.

The carbon content of the weld metal from nickel-steel electrodes was given as 0.14 per cent on page 29 of the paper. The figure was taken from the American Rolling Mill Co.'s report and should read 0.04 C. instead of 0.14 C.

S. G. Child[6] in a written discussion called attention to the author's statement that "the base metal most successful for autogenous welding is a low tensile steel of 0.15 per cent maximum carbon content," the objection to a higher carbon content being the danger of burning the steel in the operation of welding.

It was desirable before legislating on the permissible materials for welding to investigate the present commercial practice in the manufacture of welded pressure vessels. He was identified with a manufacturing plant which had for many years successfully welded pressure vessels made from the standard grade of boiler steel, of the grade specified in almost identical form in the A.S.M.E. Boiler Code, in the A.S.T.M. specification A–30, in the American Railway Association specifications and the standard specifications of the Association of American Steel Manufacturers. The tensile strength of this grade was 55,000 to 65,000 lb. per sq. in. and the carbon content usually from 0.15 to 0.25 per cent.

All locomotive boilers were built of this grade of material and were satisfactorily welded both during construction and when undergoing repairs in the railroad shops. No trouble from burning the material was experienced. If a poor weld was made by an inexperienced operator it was usually detected by a visual inspection and the part chipped out and rewelded. If the inspector failed to detect a poor weld on surface inspection it was invariably detected

and corrected when a test pressure greatly in excess of the working pressure was applied to the vessel.

He had made a careful investigation of the manufacture of welded unfired pressure vessels and found substantially the same result, namely, that the standard grade of tank or boiler steel having tensile limits of 55,000 to 65,000 lb. per sq. in. and usual carbon limits of 0.15 to 0.25 per cent ordered to the requirements of the specification of one of the above-mentioned organizations, was almost universally used.

F. N. Speller[6] asked the author whether he took into account the weakness of the metal near the weld incident to the heating of the plate. This was something that should be considered in discussing the strength and efficiency of a weld. The quality best suited for forge welding was not necessarily the best for acetylene or electric welding.

Stafford Montgomery[7] said that he gathered from the papers that there was a tendency in plain welding for foreign particles included in the base metal to migrate to the region of the weld, there forming a belt of weakness; and asked whether the author had observed in the case of resistance welding or welding under pressure, that the method tended to force out in the form of a slag such foreign particles as were usually found in that class of weld.

In his closure Mr. Miller said that as regarded efficiency of the weld he referred to cases where it was less than 100 per cent, which was always the case where the welding wire was of low-carbon steel—of low tensile strength and the plate of high tensile strength. In the tanks referred to in the paper the tensile strength of the weld was higher than the tensile strength of the plate, and purposely made so.

In order to ascertain what the conditions were, after the tank tests he had cut out a piece about 18 in. square from across the weld and then cut two different pieces from it, straightened them cold on an anvil and tested them. The plate had a tensile strength of 50,000 lb. originally and the tests were made after the tank had been stretched 7 in. It was possible to break it at around 62,000 lb. per sq. in., this high strength being due of course to the cold working on the plate during the test; and the strength of the weld, referring to the original strength of the plate, was therefore at least 125 per cent. With this method of construction the plate would break outside of the weld every time.

As to Mr. Montgomery's question, he would say that in making a flash weld some of the dirt squeezed out and the remainder was held, just as in fusion welding. The metal not squeezed out, which was back of that squeezed out, was still as effective as before. The non-metallic impurities were washed from the V by the metal flowed over the surface of the V during the welding process, and were distributed. There was a certain amount of the metal back of the welded part that was not quite welded, and the impurities distributed themselves by gravity over that section and into the V, adding to the welding material.

Discussion of Mr. Speller's Paper on Steel for Forge Welding

H. V. Wille,[8] in a written communication presented by S. G. Child, said that he had written to a large number of welded-tank manufacturers with the view of determining the present actual practice in this industry.

From the replies received it was evident that a large part of the pressure-tank practice of the present time was based on the use of ordinary grades of boiler and tank steel having a tensile strength of 55,000 to 65,000 lb. and governed by the specifications of the American Society for Testing Materials, the Association of American Steel Manufacturers, or the American Railway Association, which were practically identical and which called for rigid chemical and physical tests.

Some manufacturers were using a softer grade of steel for welded tanks with satisfactory results. This grade was equivalent to the A.S.T.M. specification A-78-21-T.

Mr. Wille believed that both of these grades of steel should be permitted for welding practice. While a number of experimental tests had been made to show the superiority of soft steels over the standard grades for welding, the cases were more or less special and were not representative of general tank practice. It was probable, for example, that welds made by the electric-resistance autogenous process without adding additional metal, should be restricted to a soft grade of steel as had been found desirable in the forge welding of steel pipe, which was lap-welded and had no metal added.

In the oral discussion following the reading of Mr. Wille's communication, questions were propounded to the author by Messrs. John A. Stevens[9] and S. F. Jeter,[10] which he dealt with in his closure.

Replying to Mr. Stevens as to the way a hammer test should be made, he said that in the case of boiler tubes a 2-lb. hammer was formerly used by his company, a pneumatic hammer being later developed on account of the danger to the operator in using a hard hammer. For large forge-welded tubes they had not yet arrived at any set standard. Anything that would not make an impression on the steel but would send a vibration through the cylinder was sufficient for the purpose. It was possible to apply static pressure to a welded vessel almost up to the rupture point without causing a fracture or even a leak. But if the vessel were struck a sudden blow, even with only a 2-lb. hammer, the vibration would carry 8 or 10 ft. from the point of impact, and that would be enough to increase the pressure and disturb the equilibrium, and cause the tube to crack.

As to the objections he had to the Code, he would say to Mr. Jeter that it was incomplete. It should state more than the minimum tensile strength: he noticed that in one place it called for 47,000 lb. and in another, for 45,000 lb., and he thought that 47,000 lb. minimum was enough and would cover the steel ranges that could be used in this connection from 47,000 lb. to 57,000 lb., as specified for "Grade A," on page 7 of the Code. The present Code requirements should be modified if welded steel is to be allowed.

Mr. Wille had asked, why not use flange and firebox steel? It was rather unfortunate that such a widely used grade as the latter should be just a little high in tensile strength, 0.15 to 0.25 carbon being just outside of the range required for good welding. It was, of course, possible to weld it, but the Boiler Code Committee wanted a material that could be welded with the least difficulty, and in spite of the inconvenience of adding another grade of steel, it would be better to have one that had been developed and shown adaptable especially for forge welding. This would be a steel of not over 0.15 carbon. Another grade not over 0.20 carbon might be added to satisfy the demands of those who wasted higher tensile strength, at least for tank cars, and that would include about half the range of the firebox steel. Mr. Wille's problem was somewhat simpler. His company used forged welds on locomotive firebox boilers for the sake of lightness and employed flange steel; all of these welds were reinforced by straps, so that the weld was not depended on to any great extent for strength.

Discussion of the Paper by Professors Fessenden and Bradford on Tests on Welded Cylinders

S. W. Miller[1] wrote that he did not believe it was good practice to heat the shells and the heads of pressure vessels in an ordinary forge fire where the flame was strongly oxidizing, and where it was impossible to keep dirt out of the weld. Even with the best facilities it was difficult enough to keep the mill scale from being included in such a weld, and the chances were that there would be defects in spite of the best practice. The results shown in the paper indicated clearly the difficulty in making a sound weld under the unsatisfactory conditions employed.

The gas-welded tanks apparently had had all the seams welded without beveling, and the heads had apparently been welded to the shells without removing the scale left by the cutting torch.

In the case of the pipe tanks the shell was much thicker than the head, in addition to which the head was beveled, so that the bottom edge of this bevel became hot and ready to weld before the shell did. The result was that there was a great chance of the shell not being brought to the fusion point and the melted weld metal not

being fused to the shell. This was true wherever one piece was thicker than another.

His experience led him to believe that it was not possible to get sound welds in this way. A single V weld was liable to be imperfect under the best conditions, although when properly made in soft plate of good quality with the proper welding wire, it was possible to bend such a weld backward without rupture, the bottom of the V being on the convex side. This was the severest test of a single V weld that he knew of, and every condition must be exactly right for it to be successful. The effect of imperfect fusion along part of the V appeared to have been considerable in the case of the longitudinal seams as shown by Fig. 28 which showed a reinforcement of probably 50 per cent of the plate thickness. Assuming it at this figure and using the formula for eccentric load stresses given in Kent's Handbook it would appear that the maximum fiber stress with a perfect weld would be about 56 per cent more than the average stress on the plate section. If the weld were imperfect, the fiber stress would increase beyond this very rapidly, and the vessel might easily become dangerous.

Cylinder No. 2 was tested to a fiber stress much above the yield point, as shown by the permanent set in Par. 28, and the results of the tensile strength in Table 3 should be taken with some caution especially since the yield points were so close to the ultimate strength. Apparently the figures given represented the strength of the material after it had been once stretched, and were not the real characteristics of the material before testing.

Recommendation (*f*) under Par. 69 for overcoming the defects noticed in the gas welds certainly should be always carried out.

It was very doubtful if the increase in grain size alone had much to do with the strength of the material, although in connection with non-metallic impurities it might be a prolific cause of weakness.

The entire paper showed the necessity for the adoption of better practices, which would doubtless be done as soon as it was fully realized by the manufacturers of tanks that some of the practices at present in use were not safe.

G. O. Carter[11] said that the man who subjected a vessel to a pressure of 200 lb. that was intended for only 100 lb., was at fault. The weld was almost always blamed if there was a failure, no matter what the real cause might be, and especially so if the vessel was made of low-carbon steel. He did not believe that makers of steel welds would suffer, however, if tanks failed outside the weld. As to correct design, he believed the convex head should be employed instead of the concave, in order that the strain should be tensile.

There were advantages in using double V welds, for with the single V there was an unbalanced load on the weld, and his company had found that nothing was gained in reinforcing a weld more than 15 per cent. There were some places where a double weld could not be made, but the circumferential welds required only 15 per cent more than in the case of longitudinal seams and they were a large additional factor of safety.

In welded construction it was possible to obtain more than 100 per cent of the deposited metal or of the base metal, but in riveted work 100 per cent could not be reached. Especial attention should therefore be given to the correct depositing of metal, and the use of low-carbon filler rods should be done away with, in spite of the fact that they were easy to work and easy to clean.

George Bird[12] spoke in approval of the double V weld and said that in experiments his company were conducting the V's on the inside of the vessel were made two-thirds the capacity of those outside. In his section it was difficult to set uniform plate from the mills. He had seen tank plate so stiff that it could not be bent and which was as hard as high-carbon steel.

F. N. Speller[4] protested against the conclusion of the authors that forged welds in cylinders were much inferior to acetylene or electric welds. For 25 years, he said, ammonia containers with dished heads had been forge-welded, the heads being of the same thickness as the shell. Failure, when it occurred, was by reversal, which would open any sort of weld. Forge-welded cylinders made under the I. C. C. specification No. 4, when tested rarely failed at the weld, however, and it was almost an unknown experience to have a dished head reverse itself.

S. F. Jeter[10] said that insurance companies were more willing to accept risks on forge-welded than on autogenously welded vessels although they considered the latter to be reasonably safe. He differed with Mr. Carter as to the use of convex heads for the reason that heads dished inwardly were better fitted to resist the stresses up to some point near rupture. The companies were not particularly interested when the weld had begun to fail.

John A. Stevens[9] closed the discussion by saying that the session had been without doubt one of the most important meetings ever held to consider welding problems. The end in view, of course, had been to obtain information as to the best materials to use for the various classes of work in order that standardization might be effected. A matter that he would like discussed was that of preheating the plates.

General Discussion

The meeting being thrown open to a general discussion of welding, Chairman Fish said that the reason for having delayed so long in getting out the unfired-pressure-vessel code had been primarily the uncertainty as to what the provisions covering welding should be. The demand was insistent for a code, and the Sub-Committee of the Boiler Code Committee sincerely wanted the best advice it could get, and was particularly desirous of getting as much real data as possible regarding construction.

C. W. Obert[13] read an extract from a letter written by Augustine Davis, Jr., president of the Davis Welding and Manufacturing Co., Chicago, in which Mr. Davis said that from his rather extended experience in welding he was certain that almost any class of pressure vessels could be welded if the proper construction was used, without any greater danger, in fact, with less danger than in the use of rivets or other mechanical means. For instance, pulp digesters, ammonia condensers for ice plants and stills for oil refineries were lap-welded. Ammonia condensers were at present and had been successfully oxy-acetylene welded. In fact, he understood they had been more successfully manufactured this way than by any other method. While failures had been made on oil stills and pulp digesters, yet there was no reason why these should not be oxy-acetylene-welded to even better advantage and more safely than by lap-welding except lack of experience and time for manufacturers to develop welding for these purposes.

J. O. Leech,[14] discussing the qualities of base metals, said that tank steel from the steelmaker's standpoint was any grade of steel that would bend or could be fabricated readily. It did not have any definite chemical or physical properties. Some railroads used very soft steel for locomotive fireboxes, while others used a medium grade. The Pennsylvania Railroad had reported that they obtained the best results from steel of 55,000 to 65,000 lb. tensile strength. Other roads wanted 45,000 to 55,000 lb. He would impress on those present that grade did not make quality, and quality did not make grade.

Professor Roark[15] said that there would be no tensile stress on the head joint of a cylinder, unless the head was of the same thickness as the shell and truly spherical, with the same radius as the shell. There seemed to be a general impression that a rounder head, convexed outwardly, would lead to additional tensile strength only on the joint, but analysis would show that such was not so.

S. W. Miller,[1] replying to Mr. Steven's request for information on protecting plates, said that this while procedure of itself would not make a good weld, it would nevertheless tend in that direction because it permitted the use of a smaller tip which did not blow the metal away, and in the case of an electric weld it would enable the welder to get better fusion with somewhat less current. It was hard on the operator with the temperature, say, 100 deg. in the shade. There were those who insisted that preheating was necessary to avoid destruction in circumferential seams, but from his experience he felt warranted in opposing this view. After-heating was no more necessary than preheating except in the case of forge welds, where it was good practice to anneal sufficiently to remove the stresses due to hammering.

F. N. Speller[4] said that with respect to forge-welded vessels, where the welds were heavy it was preferable to anneal the whole vessel to relieve the internal strain.

Compounding the Combustion Engine

Interesting and Valuable Discussion of Paper Presented by Elmer A. Sperry at the 1921 Annual Meeting of the A.S.M.E.

IN a paper presented at the 1921 Annual Meeting of the A.S.M.E., Elmer A. Sperry set forth the results of his work, extending over 30 years, in developing a successful compound combustion engine. Such engines are light compared with the normal Diesel engine, being in special cases, according to Mr. Sperry, less than one-tenth, and in some cases less than one-twentieth, the weight for the same output. A high mechanical efficiency and a distinct gain in overall efficiency from fuel to shaft were reported in the paper, as well as a very definite gain in simplicity, direct performance and smoothness of crankshaft diagram—all achieved while adhering to the best practice, namely, four-cycle operation.

Mr. Sperry's paper, slightly abridged, appeared in the January, 1922, issue of MECHANICAL ENGINEERING, which went to press before it was possible to prepare an adequate abstract of the valuable discussion it drew forth. Such a résumé, however, is now printed below and should prove of great interest to those who read or heard the paper presented. The figure numbers above Fig. 8 refer to the complete paper, and not to the abstract published in the January issue.

ORAL DISCUSSION

In opening the oral discussion, George A. Orrok[1] called particular attention to the transfer valve between the high- and low-pressure cylinders, which in Mr. Sperry's engine is the solution of a particularly severe problem. He emphasized the importance of mechanical atomization of fuel, which has proved so successful when using fuel oil under boilers. He also drew attention to the fact that the engine in question followed the accepted canons of steam-engine design.

Francis Hodgkinson[2] pointed out as important the increase of size of the compression space, which leads to detonation and is a remarkable aid to good combustion.

A number of questions were asked of the author by others present at the session, as to the efficiency of the engine, to which he gives attention in his closure.

WRITTEN DISCUSSION

J. C. Shaw[3] submitted an extended and searching written discussion, the greater part of which follows.

DISCUSSION

Mr. Sperry's engine is interesting, as well as ingenious, particularly in the methods employed in effecting the idea of compounding the oil engine, and he is to be commended for his research along the lines indicated.

It would appear on casual observation that there might be some saving in weight over the simple engine, due to the low-pressure element of the compound engine having twice as many working strokes as the corresponding part of the four-cycle simple engine. This advantage, however, is evidently more apparent than real, as will be shown later, provided the same general construction is adhered to for either engine. A similar argument has been frequently advanced for the two-cycle engine over the four-cycle for effecting weight saving, but which has not always proved correct in actual service conditions.

The claim for inherent superior economy of the compound engine over the simple engine, wrote Mr. Shaw, is to be seriously questioned and it is particularly to be regretted that the author has failed to supply any actual figures for fuel consumption to substantiate this general claim. The parallels that have been drawn with other types of machinery, as reasons for anticipating the better efficiency, are incorrect as a rule, and more or less misleading.

The compounding of the steam engine is cited, but this (as is well understood) is done entirely for another purpose, that is, to prevent the condensation and reëvaporization of the medium in the cylinders.

The author similarly makes mention of the large expansion in a steam turbine as a reason for greater expansion desirable in the oil engine, but the comparison is again incorrect. The turbine must work down to a very low absolute pressure, and the final specific volumes handled are accordingly very large. The turbine, furthermore, is not handicapped by having restricted exhaust openings. In the oil engine the back pressure cannot be less than atmospheric pressure, large expansion ratios not being required, and there must be some "toe loss" in card area, or slight pressure drop, so as to get the gases through the exhaust valves, which are limited as to size.

The author also cites the multi-staging of the air compressor as a parallel reason for doing the same in an oil engine. This is primarily done to permit of intercooling the air to reduce the amount of external work required to be done on the air. Any loss of heat in oil engines, either during expansion or compression, beyond keeping the temperatures within practical limits, conversely is to be avoided.

The author further advances the claim for superior economy by "hanging on to the pressure in the gases throughout two strokes, clear across the card twice, thus extracting much more of the power they contain." This is difficult to comprehend, as the pressure in either the compound or simple engine should follow the same general adiabatic curve of expansion, due to the burnt gases being composed of the same constituents of combustion. In the formula $PV^n =$ Constant, for adiabatic compression or expansion, the exponent n for air is 1.403, and for exhaust gases is usually taken as 1.37. To sustain or "hang on to" the pressure more during expansion as suggested, would have the effect of lowering the exponent below 1.37 and to approach the isothermal curve in which the exponent becomes unity. This would be undesirable, as it would indicate after burning and loss in efficiency. In the theoretical thermodynamic formula for thermal efficiency, the efficiency varies directly with n, and the pressure should fall rapidly enough to approach ideal adiabatic expansion. It also follows that with the adiabatic expansion less expansion ratio in cylinder is required, and should not be carried beyond what is practically necessary. The high-speed engine, especially working on the constant-pressure cycle, is prone to after burning and raising the end of the expansion curve, and the back pressure is also augmented by the choke in the exhaust valves, in itself due to the high speed. On the other hand, in the slow-speed engine the burning is much more complete in the beginning of the stroke, due to the time element being longer, and there is less restriction in the exhaust passages than with the high-speed engine.

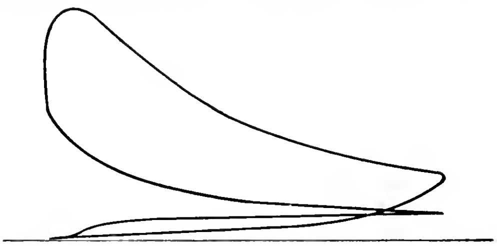

FIG. 1 INDICATOR CARD FROM PORT ENGINE OF MOTORSHIP *William Penn*

The author shows in Fig. 2 a theoretical card of a two-cycle Diesel engine with exaggerated "toe loss," and indicates in extended dotted lines the additional area which is supposed to become available with the compound effect. In contrast to this card there is reproduced in Fig. 1 on this page a tracing of an actual card taken from the port engine of the motorship *William Penn*. The cylinder size is $29^{1}/_{8}$ in. diameter by $45^{1}/_{4}$ in. stroke, and the m.i.p. of the

sard shown is 5.9 kg. per sq. cm., corresponding very closely to the normal rated power of the engine when turning at 115 r.p.m. The end of the expansion curve is about $1^{1}/_{2}$ kg. per sq. cm. or 22 lb. This curve has been extended in dotted lines by calculation to half the above actual release pressure, should it be possible to work to the lower pressure, and the additional area that becomes available is found to be less than 6 per cent. This would necessitate increasing the expansion ratio by about 27 per cent with the additional weight and friction of parts involved, and it is accordingly extremely unlikely that any improvement in efficiency could actually be realized with the greater ratio.

An actual card is given in Fig. 12 for the 7 by 11-in. engine, working on the explosion cycle. By comparing it with the constant-pressure card in Fig. 11, it is assumed that the scale is about 360 lb. to the inch, as usually employed. On this assumption the maximum pressure would be about 600 lb., and the compression pressure about half this, or 300 lb., which later is sufficient for automatic ignition with solid injection. The back-pressure line of the high-pressure exhaust as well as the air-charging line is also shown on this card. but it does not follow, as one is lead to assume, that the corresponding pressures registered outside the cylinder will be the same. It would have proved very interesting had corresponding actual cards been taken from the low-pressure cylinder, top and bottom, and had the pressures so obtained been referred to the low-pressure cylinder, as in steam practice. This would show the actual card-area losses due to pressure drops between the various cylinders, as is to be expected. It is to be noted from the high-pressure card given that the negative work of the supercharging side of the low-pressure is actually about equal to the work done by the working side, taking into consideration their relative areas as shown in engine section, Fig. 14. It would appear that at small fractional powers there is danger of overexpansion, and of the low pressures doing very little work and acting as a drag on the system. The engine differs from a compound steam engine in not being able to vary the "cut off" of the low-pressure for equalizing the powers and expansions between cylinders to suit the actual conditions.

The author, however, has furnished us with some ideal cards shown to small scale, Figs. 3 to 8. Comparing cards 5 and 6, showing high-pressure cylinder theoretically functioning both as constant-volume and constant-pressure cycle with same compression pressure, it is seen that the compression pressure is about 650 lb. and the explosion pressure for the constant-volume cycle is over 1000 lb. This is estimated from point *B*, given as 113 lb. The increased theoretical efficiency of the explosion card is readily understood from the theoretical formulas, and is on account of the greater card area available in common with the high maximum pressure employed. It is seriously doubted, however, if the theoretical card could be anywhere nearly approached in practice, especially in the larger commercial sizes. This is on account of the high shocks and strains that would be produced and the heat troubles encountered within the high-pressure cylinder and transfer valve, but not so evident in the small experimental engine of small dimensions.

Mr. Sperry strongly advocates his high-pressure explosion engine for cargo-ship propulsion for replacing the present well tried slow-speed direct-drive engine. The latter, though acknowledged by him as being responsible for the present high standard of the motorship, he particularly criticises for its excessive weight. In so doing he has overlooked completely the shortcomings of the explosion engine and high-speed engine. The explosion engine is inherently unsuitable for marine drive, due to the shocks at dead center and lack of flexibility at reduced powers. The slow-burning engine, on the other hand, is specially adapted by lack of shock and by great flexibility, due to having the burning take place after the piston passes dead center, without any appreciable rise in pressure.

To prove his point for saving in weight the author mentions a mean effective referred pressure of 300 lb. for the high-pressure cylinders. This has been doubled or referred to one high-pressure cylinder only and increased to 660 lb., and it is pointed out that this is ten times that usually employed in the simple engine. From this he infers the weights, respectively, should be inversely in the same proportion. The comparison of mean pressures would be more nearly correct had that of the compound been referred to the low-pressure cylinder, and which in the case of 1 to 10 engine, would have brought it down to that of the simple engine. The comparison of this high-speed engine on a weight basis, without taking into consideration the additional weights of the complicated clutches and gears also involved, with that of the slow-speed direct-connected crosshead engine is considered very unfair. An attempt has been made by the writer to arrive at a true comparison between the particular compound engine and a simple engine of similar construction. In a contemporary copy of the Sperry Company's publication, the *Sperryscope*, there is shown in outline an engine having the same general overall dimensions as shown in Fig. 14, and designed for the same r.p.m., namely, 400. From this it can be assumed that the engines are one and the same. The engine illustrated in the publication is direct-connected to a 50-kw. generator, and the statement is made that two engines placed end on end are suitable for driving a 100-kw. generator. Acting on the above clue and suggestion made, a tandem compound engine, has been laid down from Fig. 14, and to the same scale has been drawn a Burmeister and Wain auxiliary engine, designed for the same r.p.m., and for direct connection to the same size of generator. This engine, which is a new type, designed with the idea of installing in limited spaces, is four-cycle, totally enclosed, and has three cylinders of $11^{3}/_{16}$ in. diameter by $13^{3}/_{4}$ in. stroke. The diameter of the low-pressure cylinders of the Sperry engine is figured from the 1 : 10 ratio as 22 in., and the high-pressure cylinders are 7 in., as given, by 11 in. stroke.

The simple engine was found to have about 55 per cent less cubic displacement than the compound, which figure does not take into consideration the supercharging displacements of the low-pressure cylinders, but which are essential accessories to the high-pressure cylinders. There are three working cylinders as against six, and one set of sizes of parts instead of the two sets required for the compound arrangement. The compound engine, furthermore, has a larger number of objectionable automatic suction valves, inaccessibly located, and the trunk type of air piston is a type of construction to be avoided, having been abandoned by most two-cycle builders as unsatisfactory in operation.

The weight of the standard Burmeister and Wain engine, including attached piping, grating and flywheel, and as heretofore built, is 350 lb. per s.hp., and not 450 lb., referred to by the author in error, and it should be added here that, by a newer construction, the weight is actually being reduced by 10 to 15 per cent below the 350 lb.

The actual fuel oil consumption on the above standard Burmeister and Wain engine, as used with twin-screw vessels, is from 0.38 to 0.39 lb. per b.hp. With oil of 19,000 B.t.u., and with the new special slow-speed engine, adapted to single-screw vessels, the consumption is about 0.02 lb. lower. It is thought that these figures will stand comparison with any that may have been obtained with the compound engine, though not given in the paper.

In Fig. 17 is shown by the author a 1550-i.hp. Burmeister and Wain marine Diesel engine, coupled to a generator in the background, and which appears small due to the effect of perspective. The author states that the generator so shown (but used for test purposes only), "forms the full load of the engine." He has been misinformed, as the generator in question is used for absorbing only the power of three cylinders at a time of the particular engine, with the other three cylinders acting as additional load.

Author's Closure

In closing the discussion, Mr. Sperry wrote substantially as follows:

Mr. Orrok and Mr. Hodgkinson have touched on a very vital point. The transfer valve has been a stumbling block ever since the first compound was conceived, and every one has realized it, except Junker, who must have "slipped a cog" when he tried to uncover a valve at about 2700 deg. fahr. temperature. But such are the temperatures to be coped with.

The air injection of fuel mentioned by Mr. Orrok is most interesting. If air is compressed to the point required in the Diesel cycle, we get a temperature of about 1200 deg. If this air is compressed again to another 500 lb., which is the regular pressure of the air when it is used, there results another great increase in temperature. When this air is injected into the cylinder, that temperature drops back again, creating a tremendous refrigerator effect just where a refrigerator cannot be allowed. The incandescent

air must not be refrigerated; all the heat must be left in it. It ought to be guarded still further, because it has been calculated that the amount of heat taken up in the vaporization of the fuel is 80 per cent of the heat in the air.

As to the efficiencies, it can be said that they approach more nearly the theoretical air cycle efficiency than any engines that have ever been built. In Italy, a 7 by 11-in. Diesel engine, which is the size of the engine shown in the paper, without the low-pressure cylinder, running at 450 r.p.m. was found to give 13 hp. per cylinder. If this engine were to run at 400 r.p.m., the speed of the Sperry engine, it would give about 22 hp. in the two cylinders. In the Sperry engine, with these two cylinders and the low-pressure cylinder, we have 220 b.hp. It has been run a great many hours at 180 b.hp. This is about seven times as much power as the Diesel engine. But there is not seven times as much machinery operating, simply one more piston. Cards have been taken repeatedly from the Sperry engine to check up the mechanical losses and these are about 10 per cent. In larger engines, between 40 and 50 per cent thermal efficiency at the shaft is anticipated.

Now, as to large engines. What are the limitations on Diesel engines today? They are cylinder size and thickness of cylinder wall. It is impossible to go much above 1¼ in. in thickness of cylinder wall, nor much above 30 in. in diameter. With this in view and with 29-in. cylinders running at 800 or 900 ft. piston speed, and leaving only four of these combustion cylinders in line, the layouts indicate that an 8,000-hp. engine would be obtained. With six combustion cylinders in line, this would be 12,000 hp. So there is no trouble about the size. Dr. Lucke, of Columbia, has been good enough to say that the compound has solved the problem of making large oil engines.

Mr. Shaw falls into the almost universal error in visualizing combustion engine compounding. He takes a normal Diesel card of the *William Penn* engines and extends the expansion down to one-half of the usual pressure at which the exhaust valve opens, hoping thereby to set forth a convincing argument against compounding. What he actually succeeds in doing is to produce a real case of what he characterizes as "toe loss." In applying this expression to Fig. 2, he seems to have overlooked such an insignificant point as the line XY. The difference between the two propositions is as great as that between the poles. It is just this attempt to do low-pressure work in a high-pressure cylinder that is condemned and has been the compelling reason for adoption of the compound principle in steam as well as combustion engines.

Were this all we did in compounding, however, it would be even more useless than Mr. Shaw states it to be. He seems to think that the only gain in weight we have is the double use of the same low-pressure cylinder for two combustion cylinders "provided the same general construction is adhered to," etc. But isn't this begging the question? Is the same general construction adhered to? Hasn't he missed several other points, such as the compound combustion cylinder being enabled to handle a great many times the weight of air compared with the simple Diesel—not only many times the weight of air, but many times the fuel with more complete combustion than in any simple engine? Again, the point of very great gain in chilled perimeter and surface per unit volume of the power gases. A number of other definite differences between the compound and simple engine, it is felt, are quite completely set forth in the paper.

The expression "back pressures" appears at several points as being the great argument against compounding. A compound engine of any kind invariably develops back pressure on the piston of the next higher stage. All of these facts have had to be considered in compounding steam. In the early history of this earlier art all of these objections were doubtless dragged forth with many others, groomed and arrayed in opposition to the unthinkable change from simple to compound. Now, as a matter of fact, not only have none of these features been found prohibitive, but they have been so minimized as not even to be serious, and this has been the proceeding in the present instance.

With reference to the comparison made between Figs. 5 and 6, where the constant-volume and constant-pressure cycles are shown doubt is expressed if the theoretical card is anywhere nearly approached in practice. It is believed that Fig. 12 is an answer to this.

The predictions as to shocks, strains and heat troubles are on a par with many other of the imaginary troubles. The facts are there is nothing that approaches shocks in the high-intensity burning shown. The very time factor that so alarms Mr. Shaw carries with it its own remedy in relation to its actual effect on the heat gradient and heat losses. Mr. Ricardo of England has evidently gotten sight of this phase of these interesting phenomena.

There is no lack in the flexibility of the engine employing the high-intensity burning card.

With reference to the comparison of the compound with the simple engine, inasmuch as there is no such thing as a previous compound combustion engine to compare with, the author is perfectly justified in referring all of the mean effective pressures back to the only thing that previous engines do have, viz., the combustion piston area, and the evident value in securing ten times the net mean effective pressures to the crank for each fuel injection, together with a very much better distribution of the power application to the crank from any single injection, it is felt needs no further emphasis here.

In connection with the generating sets referred to in the *Sperryscope*, the author cannot agree that the engine that is lighter than the standard General Electric or Westinghouse generator to which it is directly coupled is not exceptional, especially considering that this applies to the ordinary run of engines, designed with no thought whatever of lightness. Fortunately it is not necessary to compare the compound with other than trunk engines to bring into strong contrast the gain in weight. There are large numbers of these engines in service running between 150 and 350 lb. to the b.hp., many of them running at much higher piston speed than the comparatively low piston speed of 735 ft. employed in the Sperry 7-in. engine. However, when employing the same class of refinements as used in submarine engines, the weight comes down to a very low figure, as indicated in the paper.

A point not emphasized in the paper is that in the compound much larger power units can be made in trunk engines than possible with simple engines, the controlling factor covering this point, as is well known, being the relation of combustion piston and the wrist-pin bearing diameters. This gain follows from the fact that a given combustion cylinder in the compound accommodates from four to six times the fuel with a corresponding gain in power for the size. Naturally the alternative of this is that with the compound we do not have to resort to crossheads until we reach four to six times the power of the simple engine per combustion cylinder at the same piston speed and revolutions. It is felt that these are definite gains that cannot be neglected. The crosshead type of engine is just as applicable to compounds as to simple engines. The builders of crosshead engines are driven to adopt this from the limitations given above, whereas so long as excess slipper area is available with ample lubrication, and it shows practically no wear, many of our leading engineers are commencing to believe that the trunk engine is superior, and we know that it is lighter.

With reference to the heavy engines, the author makes it clear that a plurality of unit engines is necessary in a ship, but in all instances twin screws have to be resorted to, where a single screw would be much better all round. It is believed that plural units with their simple slow-speed gears will forge ahead and win the place that they deserve, especially in view of the complete safeguards of the air-gap clutch, which our critic seems to overlook, making the most completely maneuverable ship yet produced.

As to the generator in Fig. 17, this being a photograph of a foreign-built engine and not one of Mr. Shaw's construction, there seems to be doubt as to the accuracy of the author's remarks concerning it. Halfway measures are not usually adopted. A similar photograph of the Maume engines, which are still larger than the one of Fig. 17, where a full-load generator was used to his knowledge, shows about the same contrast. But suppose the statement to be correct. Does Mr. Shaw think for a moment that if the generator shown were to be multiplied in size by the cube root of 2 the contrast between Figs. 16 and 17 would be substantially altered?

If present signs are any indication, it will soon be possible for the author's critics to satisfy themselves as to all points of efficiency and economy of these engines under practical conditions of operation. This, it would seem to the author, should settle all controversial points and while the engines will probably not be above criticism,

SURVEY OF ENGINEERING PROGRESS

A Review of Attainment in Mechanical Engineering and Related Fields

Investigation of Oscillatory Phenomena in Turbo-Generators by Means of a Vibrograph

By DR. JOS. GEIGER

HITHERTO investigation of oscillatory phenomena in high-speed machinery and, in particular, turbo-generators, has been limited to the calculation of the critical speeds at which the shaft begins to exhibit oscillatory phenomena. In the majority of cases only the first or lowest critical speed was determined, but even these limited calculations were often more or less uncertain, because, in the case of shafts located in more than two bearings, the method of supporting the shaft and of holding it in position by nuts, etc., introduces important factors of which we do not know much but which materially affect the results of the calculations. Oscillations not due to the rotation directly but induced by the rotors, housings, foundations, etc., were as a rule not predetermined at all. Because of the lack of proper instruments, observations were inexact and in many cases incomplete, it being entirely impossible to determine without proper instruments the magnitude, direction, and frequency of the various vibrations, particularly where they were superposed.

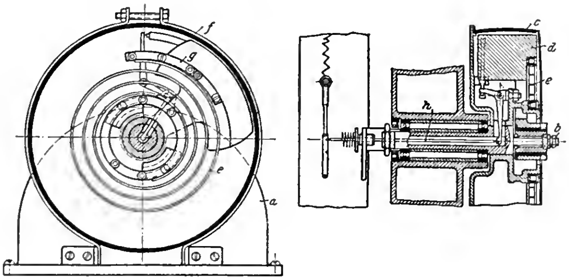

Fig. 1 The Vibrograph

As long as the vibrations were such as not to imperil the structure they could have been neglected; the author, however, ran into a case where something had to be done. In this case he had to deal with a 10,000-kw. turbo-generator running at 3000 r.p.m. The unit ran very nicely for a while and then powerful knocks appeared in the exciter bearing. A series of experiments designed to discover the cause of the trouble proved to be unsuccessful and it was decided to make use of a vibrograph after the ordinary seismograph proved to be unsuitable for this particular purpose. The vibrograph, Fig. 1, was developed during the war to investigate oscillatory phenomena in high-speed Diesel engines and their foundations. It is based on the same principle as the various seismographs, namely, a properly suspended heavy mass oscillating but not in tune with the vibration of the body under investigation. The relative motions of this latter and the inert mass represent the absolute oscillation of the body under investigation. The difference between the vibrograph and the siesmograph or pallograph, (which latter is something like the seismograph), lies mainly in constructional details and to a certain extent in the method of operation. The frame *a* is set or screwed on to the element under investigation, such as a machine part. It is provided with an axle *b* with housing *c* attached to it, and the inert mass *d*, which is rotatably attached to the axle and connected with it by means of wheel *e*. The axle, clamp, and inert mass can be rotated into any position desired and held by tightening the band *f*. If the insert mass lies vertically under the axle, the device can oscillate horizontally; if it is located at the same elevation as the axle, the device begins to oscillate vertically.

The tension of the spiral spring, which is different in the two cases, is each time so adjusted by shifting or clamping the ring *g* that the scribe lever moves about the central position. Of course, the device can record also oscillations occurring at an angle to the horizontal and may be itself placed at any angle to the ground level so that with the same apparatus one can obtain records of disturbances no matter in what direction they may occur. In this respect the vibrograph is different both from the pallograph and the seismograph, in addition to which the vibrograph has the still further advantage of smaller size and smaller weight, the latter being only 6.5 kg. (14.3 lb.), and the size 200 by 200 by 200 mm. (Say, 8 by 8 by 8 in.)

The relative motions of the inert mass of the vibrograph and the cup surrounding it take place tangentially to the shaft *b* and are converted by two angular levers, first into radial and then into axial displacements; they are then transmitted by means of the needle *h* located inside of the hollow shaft and the needle records them on a paper band driven by clockwork.

As the weight of the vibrograph is only very small as compared with seismographs, its sensitivity and magnification are not as great. While seismographs can record very slight movements, such for example, as are produced by distant earthquakes, the range of the vibrographs begins only with much coarser vibrations and extends over the range of those met with in practical engineering up to, say, displacements in excess of 1 cm. (0.4 in.) and oscillations of the order of frequency of 15,000 per min. On the other hand, the vibrograph is more sensitive and handier to use than the Schlick pallograph.

This vibrograph was used for testing the 10,000-kw. turbo-generator set in which vibration was giving trouble. After some testing at various points on the foundations, it appeared that the best way to get a clear idea as to the vibrations taking place would be to obtain a record of oscillations at the three main bearings (front turbine bearing I, double bearing II, and generator and rear turbine bearing III).

While, in the first place, it was important to measure the vertical vibrations, there were also strong axial vibrations in the neighborhood of bearing III. While the presence of such vibrations may be quite surprising at first glance, as the turbine shaft does not produce forces acting on the axial direction, the explanation of the presence of axial vibrations lies in the fact that bearing III was located not directly over but somewhat off the neutral axis of the cross-beam lying underneath. Because of this, the forces which generated the vibrations in a vertical direction tended also simultaneously to create twisting actions about the neutral axis, which appeared then as powerful axial oscillations. A record of these twist motions by means of a torsiograph proved the correctness of this explanation. Furthermore, the vibration at bearing III was much stronger than either at II or at I, and indicated the presence of resonance, as appears from the vibrograms reproduced in the present article.

The magnification was in every case 10.72 times. While there were reasons to believe that resonance vibrations might be present in this case, the origin was not sufficiently clear, as according to previous observations the first critical speed of the turbine shaft lay around 1650 r.p.m., which was confirmed by the vibrogram. But, according to the statement of the turbine builders, the second

critical speed should have been much beyond 3000 r.p.m. which latter was the operating speed.

The author has therefore determined the natural periods of oscillations of the individual parts of the foundation and machinery and, in particular, the turbine shaft. The vibrograph was also used for this purpose as part of the following simple process. The vibrograph is attached to the part of the foundation under investigation and the paper band is started so that the stylus records a straight line; then a sufficiently heavy weight is suddenly dropped down [65 kg. (143 lb.) from a height of 70 cm. (28 in.) was found to be sufficient in the present case]. The vibrograph records then the vertical oscillations (Fig. 4) of the respective part of the foundation. A similar test with proper modifications will give the horizontal natural period of oscillations of the same and other parts.

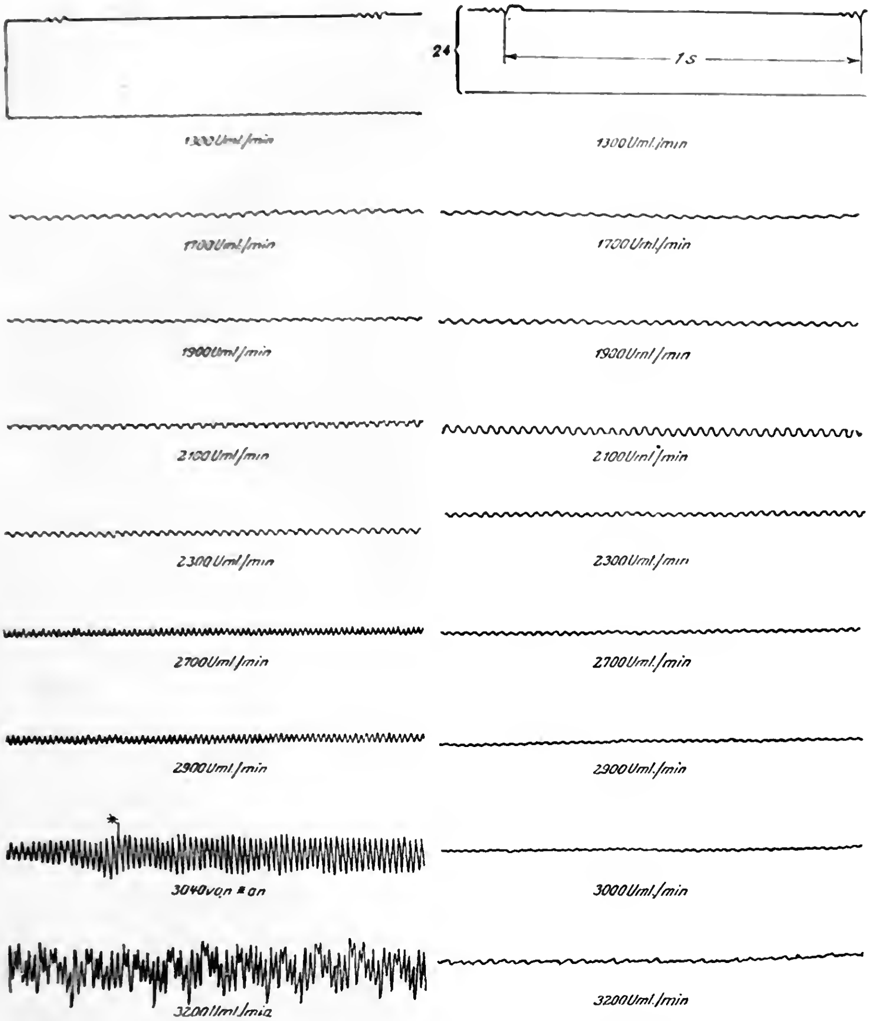

Fig. 2 Vertical Oscillations of the Generator Bearing Before (on the Left) and After (on the Right) Reinforcing the Beam Underneath It and Its Two Supports

(*Uml./min.* = r.p.m.; *von* an* = from* on.)

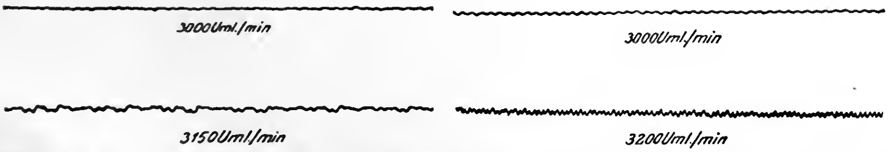

Fig. 3 Vertical Oscillations of the Double Bearing Between Turbine and Generator Before (on the Left) and After (on the Right) Reinforcing the Cross-Beam and Its Two Supports

(*Uml./min.* = r.p.m.)

The vibrograph was also used to determine the natural oscillations of the turbine shaft, but in a different manner. The vibrograph shaft with its inert mass and cup was removed and instead an angle lever with a second needle built in (Fig. 5). The angle-lever holder *a* may by means of nut *b* be shifted into any desirable position on the bearing. The upper part of the turbine housing was removed and the needle connected with the outer rim of a wheel fitted, after the bearing block of the vibrograph was attached, to the upper face of the bottom half of the turbine housing.

The paper band is then started and a shock given (by a piece of

gas pipe) to the turbine shaft or the hub of the wheel. It is not necessary to apply much force in doing this. The vibrograph records then the natural oscillations of the shaft, from which one can determine their period though not at the lowest level.

The remainder of the article gives further details as to the application of the vibrograph and shows how corrections may be made in the turbine supports by means of the information derived from its use. This part of the article cannot be abstracted owing to lack of space. (*Zeitschrift des Vereines deutscher Ingenieure*, vol. 66, no. 18, May 6, 1922, pp. 437–440, 35 figs., *deA*)

ENGINEERING MATERIALS (See Testing and Measurements)

Formation of Cracks in Boiler Plates

Formation of Cracks in Boiler Plates, Dr. B. Strauss and Dr. Ad. Fry. It would appear that low-carbon steel which has been cold-worked and then heated to a blue heat shows pronounced brittleness when tested at ordinary temperatures, but until lately it has been practically impossible to recognize this brittle condition. The method of etching developed in the experimental laboratory of the Krupp Company, however, makes it possible to recognize the brittleness resulting from blue heat by observing force influence figures.

These force influence bands were discovered not only in old defective boiler plates, but also in new plates after they were heated to 200 deg. cent. (392 deg. fahr.) and straightened in a machine, which means that they have undergone cold working similar to the bending of the plates.

It was noted, however, that these force influence bands did not appear in all soft steels and sometimes appeared only in the zone of high-phosphorus segregation but not in the low-phosphorus surface layers of the plate. Their appearance is therefore dependent on the composition of the metal.

In addition to composition, the temperature at which the plate was finished in rolling is important. Plates which left the rolls fairly dark sometimes showed bands, while plates finished in the rolls at a higher temperature were usually free from the bands.

An important influence on the behavior of the plates is exercised by the manner of their annealing. Plates which were annealed above the transformation point Ac_3 showed force influence lines after bending only in the phosphorus layers, while in plates annealed at a low temperature their presence over the entire cross-section was very pronounced.

Notched-bar impact tests on various specimens have confirmed the original statement that soft steel worked cold or at blue heat is brittle when tested at room temperatures. It has been found, however, that plates, which after bending and annealing are brittle at ordinary temperatures are tough when tested at 200 deg. cent. (392 deg. fahr.), regardless of any previous treatment they may have received.

A supplementary series of warm notched-bar impact tests were carried out. The results of these tests are shown in Fig. 1. The curve shows a rapid increase between 100 and 150 deg. cent. (212 and 302 deg. fahr.), and a sharp turn above 150 deg. cent. Above this temperature the values approach those of the plates annealed at 900 deg. cent. (1652 deg. fahr.).

From this investigation it would appear that boiler material shows in most cases a much higher toughness in the warm condition than in the cold; that the formation of cracks is promoted by allowing the boiler to cool off, and that in many cases cracks are caused by the impact effects when cleaning the boiler or calking it, a result which might be prevented by properly appreciating this condition and taking due care to avoid it. This may explain how microscopic cracks can lead to large cracks during the hydraulic test through the impact effect of the pump stroke, or may lead to an explosion through the breathing of the boiler. (*Stahl und Eisen*, Aug. 18, 1921, pp. 1133 and following, translated in *Forging and Heat Treating*, vol. 8, no. 5, May 1922, pp. 225–229, 23 figs., *et*)

FOUNDRY

Tropenas Converter for Making Steel, S. R. Robinson. The Tropenas process is a variation of the Bessemer intended for making steel in comparatively small lots—one to two tons. The present article applies particularly to practice with vessels of two tons capacity. The process consists in melting a mixture of low-phosphorus pig iron and steel scrap in an ordinary cupola and transferring this metal to a converter in which a blast of air is allowed to impinge on to the surface of the metal. The article gives practical advice as to the carrying on of the process. The following information is given as to the cost of operation.

Assume a charge of 60 per cent pig iron and 40 per cent steel scrap; also a combined cupola and converter melting loss of 18 per cent. Then:

Cost of 1200 lb. pig iron	$21.43
Cost of 800 lb. steel scrap	9.40
Total	30.83
Allowing 18 per cent loss, cost per ton	36.38
Cost of 20 lb. ferromanganese	0.60
Cost of 12 lb. ferrosilicon	0.36
Cost of 300 lb. coke	0.90
Cost of repairs	1.00
Cost per ton of steel in ladle, exclusive of labor	$39.24

HYDRAULICS

Pipe Friction and Pump Efficiency, Wm. Brazenall. Tests to establish comparative performance for three types of pumps, namely, turbine, three-throw ram, and differential ram.

The tests are of interest as they are carried out under practical working conditions, and, among other things, indicate the relation between the pipe friction and the pump efficiency. The results are given in the form of tables. One of the interesting features of the article is that it presents the results in units of an electric horsepower and also British monetary units, the intention being to find an economic size of pipe, which, according to the definition given by D. M. Mowat, is such a pipe that the frictional losses may not be greater than the loss of interest on capital used in installing the pipe which will greatly lessen the frictional losses. INTERNAL-COMBUSTION ENGINEERING

Airless Injection System for Oil Engines

Airless-Injection System for Oil Engines, Edwin Lundgren. Description of results obtained by K. J. E. Hesselman in Sweden, known as the successful designer of the original Polar-Diesel engine. One of the most important features of the new system lies in the design of the fuel valve. After the fuel enters the valve it is forced through a high-pressure filter of a special design. When the fuel pump delivers a certain accurately determined amount of fuel to the valve, the pressure within the valve rises to such an extent that the pressure of the spring (about 4000 lb. per sq. in.) is overcome and the fuel is squirted into the cylinder through a nozzle and a burner provided with a limited number of fine holes arranged in definite manner suited to the form of combustion space.

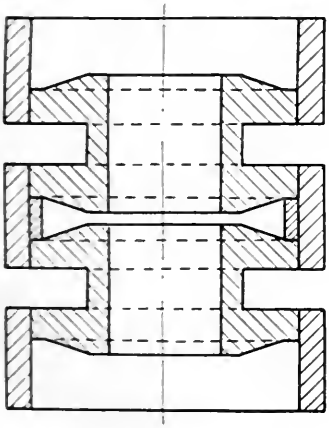

Fig. 2 Spring Elements in the Fuel-Injection Valve of the Hesselman Solid-Injection Oil Engine

In spite of the high pressure exerted on the fuel-valve spring it is of very small dimensions. The fundamental idea of the spring was to use the deflection of circular steel disks supported but not fixed at the edges. A mathematical investigation of the problem confirmed by experiments showed that the deflection attained a maximum when the disk was provided with a hole of a certain size, some of the data of this investigation being shown by curves in the original article. The form of the spring element finally adopted is shown in Fig. 2. Two steel disks are united by an inner circular web to a double disk. The spring is built by a number of these spring elements connected to each other by means of shrink rings and separated from each other by annular distance pieces. The tension of the spring is adjusted by means of a nut on top of a valve which forces the spring spindle downward. This spring spindle passes through a packing of suitable material which prevents leakage. Once adjusted the spring spindle is said to stay stationary and there is no trouble in keeping the packing tight.

The motion of the fuel valve therefore meets no frictional resistance. Consequently the lift of the valve is determined solely by the pressure of the fuel pumped or rather by the amount of oil delivered by the pump to the valve. As this amount must be proportionate to the lead, the lift of the valve must also correspond to the same.

Tests described in the original article were made to show the relation between load and valve lift. The fuel pump used in the Hesselman engine is said to be of novel design. It has only one plunger, even if used in multiple-cylinder engines. Consequently it has to run with at least such a speed that its number of pressure strokes corresponds to the number of power strokes of the engine. The amount of oil delivered each stroke is controlled by a common suction valve which is under the influence of the governor and may also be adjusted by hand. (*Motorship*, vol. 7, no. 6, June, 1922, pp. 444–445, 4 figs., *d*)

MACHINE PARTS AND DESIGN

Pulley Design for Steel Belt Drives

Machinery Driven by Steel Belts, John D. Knox. Steel bands have recently been produced in America having no joints or welds (Power Engineering Co., Youngstown, Ohio). In the process employed each band is rolled from a section of seamless tubing of special chemical and physical qualities or from other kinds of endless rings. The steel belts are made in various widths up to 6 in., dependent upon their ultimate use and the horsepower to be transmitted.

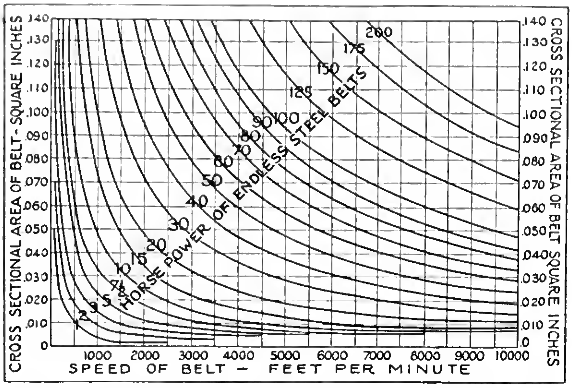

Fig. 3 Curves Representing the Horsepower of Endless Steel Belts for Various Speeds and Cross-Sectional Areas

It is stated that the drives to which the steel belt is especially adopted are air compressors, turbines, fans, motor-generator sets, grinding and polishing wheels and high-speed hot and cold saws. The bands can be run from 12,000 to 18,000 ft. per min., provided the pulleys will withstand the centrifugal force. To secure an even distribution of power over the entire width of the steel belt in order that one edge may not be stressed to exceed its breaking strength and thus result in failure of the entire band, care must be exercised in installing the belt. To obtain a linear speed from 10,000 to 15,000 ft. per min. the diameters of the pulleys are increased, which permits the use of a steel belt about half as wide as those running at ordinary speeds. But since the speed is accomplished by an increase in the diameter of the pulleys, it is possible to increase the thickness of the band, which in turn permits an additional decrease in the width.

The relation of pulley speeds to belt widths and thicknesses are such that about a 50 per cent increase in the diameter of the pulleys decreases the width by a half. Therefore, the problem of belt width, thickness, and speed ultimately resolves into one of pulley design. The curves in Fig. 3, which represent the horsepower of belts for various speeds and cross-sectional areas, illustrate this

point. For example, an 8-in. diameter pulley at 1500 r.p.m. has a speed of about 3000 ft. per min. A belt 2 in. wide and 0.010 in. thick will transmit about 13 hp. If the pulley is increased to 12 in. in diameter the speed becomes approximately 4500 ft. per min. and the thickness can be increased to 0.015 in. The sectional area, therefore, can be increased from 0.020 to 0.030 sq. in. The latter belt as shown in Fig. 3, will transmit 28 hp. In other words, the width can be decreased to one-half of its original width. A diagram which is included in the original article shows the proper speed of belts in relation to the pulley diameter and the revolutions per minute and the linear speed of the circumference of the belt in feet per minute.

From actual operation it has been found desirable but not necessary to use large-diameter pulleys, the larger the better within reasonable limits. They may be relatively narrow and lightly constructed. Pulleys which are less than 4 in. in diameter are not desirable.

To prevent slippage and to cushion the belt the faces of the pulleys are covered with sheet cork. This material will stand compression and still recover its original shape; its adhesion to the steel belt as well as the cohesion to the pulley is satisfactory. Since the cork facing is attached more securely to a rough surface than to a smooth surface, the face of the pulley is either turned with a rough cut or roughened with a file, and made flat or with a slight crown. The life of steel belts has not yet been determined. (*The Iron Trade Review*, vol. 70, no. 16, Apr. 20, 1922, pp. 1114–1116, 6 figs., *dp*)

Bevel-Gear Design, F. E. McMullen and T. M. Durkan. It has been common practice in the past to use in designing bevel-gear teeth, spur-gear formulas such as those of Brown and Sharpe. The Gleason 0.3 and 0.7 long- and short-addendum tooth was brought out to improve this condition and various other alterations of the standard spur-gear design have been used, but for the most part these can be applied to certain combinations only and therefore are not universal. Recent applications of bevel gearing covering a wide range of ratios have made it imperative that a progressive system embracing all ratios and any number of teeth in common use be worked out. An investigation conducted by the Gleason Works with the idea of developing a practical system of designing the quietest form of teeth consistent with strength and wearing considerations has resulted in a simple table. A system has been developed applicable to any pair of generated spiral or straight-tooth bevel gears operating at right angles where the pinion is the driver and has ten or more teeth. It does not apply to bevel gears cut on former-type planers.

The system is described in some detail. It may be mentioned here that the principal qualities considered arranged in the order of their importance are quietness, strength, and durability. As regards quietness, it has been found that bevel gears cut with a lower pressure angle operate more quietly than those cut with a higher one, other conditions being equal. The basis of the system is therefore the use of the lowest pressure angle which will not sacrifice strength by using excessive undercut. Moreover the selection of a low-pressure angle in preference to a higher one does not necessarily result in a considerably weaker tooth, because the stronger section of the higher-pressure-angle tooth is offset by the greater arc of action with the lower angle. The question of durability is somewhat complicated and is discussed in the original article.

The author expresses the opinion that a standard non-interchangeable system, possibly along similar lines to the one developed for bevel gears, is needed for spur gears. He claims that such a system would be of as great importance as a standard interchangeable system, since a large proportion of spur gears like bevels are intended to operate in pairs only. The concessions made to allow interchangeability are so great that the case of the non-interchangeable gear should be granted as much consideration in the way of a standard system as is given to the interchangeable gears. (Paper before Buffalo meeting, American Gear Manufacturers' Association, abstracted through *Automotive Industries*, vol. 46, no. 20, May 18, 1922, pp. 1064–1068, 8 figs., *pA*)

MECHANICS (See Machine Tools)

MACHINE TOOLS

Experiments on the Action of Cutting Tools

An Account of Some Experiments on the Action of Cutting Tools, Prof. E. G. Coker and K. C. Chakko. Description of experiments made on the action of a cutting tool by the aid of polarized light.

The principle used is described as follows: Nearly all transparent bodies when loaded become doubly refractive, and a ray of ordinary light passing through the material in a state of stress is subjected to a selective retardation whereby its transverse vibrations lag one behind the other. No effect is visible to the eye, since ordinary light consists of such a complex system of transverse vibrations that the eye is unable to detect what is going on; but if ordinary light is, as it were, strained through some kind of sieve whereby a homogeneous character of a particular kind is imparted to it, the effect of stress in the material becomes apparent. The most convenient apparatus for obtaining the homogeneous light mentioned is a crystal of transparent calcium carbonate, cut in a special way invented by an Edinburgh optician, William Nicol.

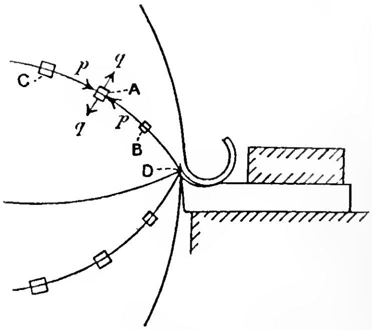

Fig. 4 Disk, the Edge of Which Is Being Turned Up in a Lathe

Ordinary light, after passing through such a crystal, is found to execute its transverse vibrations in one special plane, and this unilateral kind of light is usually called polarized light; and although this is not a very happily chosen designation, yet it seems to be so firmly established that it is hardly possible now to replace this term by a more appropriate one.

If a stressed body is placed between a pair of Nicol prisms and a beam of light is passed through the combination, color effects are observed which are due to the fact that the plane polarized light from the first prism is broken up by the stressed material into two sets of plane vibrations of light, which travel at different velocities through the material. Not only do these two systems of waves travel at different velocities, but they vibrate in planes at right angles to one another. The function of the second prism is to select components in some definite plane from these two systems, so that these latter will interfere with one another. Interference between two sets of light waves in the same plane is visible to the eye, when the light passing through the object under stress is projected on to a screen, and if white light is used, brilliant colors of a rainbow pattern appear, and indicate in a particular manner, to be described later, the stress in the material which the light has passed through. It is owing to this effect that an optical analysis of stress distribution in a transparent body is possible.

As regards the condition of the stressed body itself, the authors consider this to be a plate loaded by forces acting in its plane. This is illustrated by reference to an example drawn from the case of a disk, the edge of which is being turned up in a lathe as shown in Fig. 4.

Select any point A in that disk which has a definite and invariable position with regard to the point D of the lathe tool, and imagine a small square placed centrally over the point A, as shown. If this square is set in one particular position, it is capable of proof, as textbooks show, that the stresses at that point in the disk are perpendicular to the edges of the square and are not so for any other angular position. Further, the intensities of these stresses

p and q are such that one is the maximum stress at the point A and the other is the minimum stress at the same point. If by any means it is possible to measure the intensities of p and q and their directions, then it is quite an easy matter to find the stress at the given point in any other direction. The principal advantage of the experiments described here is that both p and q can be measured, and their directions can also be determined at any points A, B and C, provided the law of the optical effect continues to hold. The trial square can, in fact, be moved from point to point, as indicated on the figure, and for each position, the direction determined in which it must be oriented to give stresses normal to its edges. These stresses are distinguished from any others by referring to them as principal stresses, since all others can be derived from them by simple means. It will be convenient here to describe how the directions of principal stress are obtained experimentally by reference to a disk or plate subjected to the action of a cutting tool. For this and all other optical experiments described here, the polarizing and analyzing Nicol prisms are set with their own principal planes crossed at right angles. Now it is an ascertained fact that the two sets of waves into which the stressed body divides the light ray are also perpendicular to each other and the directions of their vibrations are those of principal stress. Light, therefore, is stopped everywhere in the plate where the directions of the prisms correspond to similar directions of principal stress, and a series of black bands can be obtained by simply turning the prisms round until the whole field of view has been covered, each direction being marked from the index plates attached to the prisms.

It will be noticed, when this is being done, that although the black bands move, the colors remain stationary, so that the indications of stress intensity are not dependent on the angular rotation. A set of lines marking the centers of these black bands is shown in Fig. 5-b and the inclination of the stress in both work and lathe tool are marked thereon.

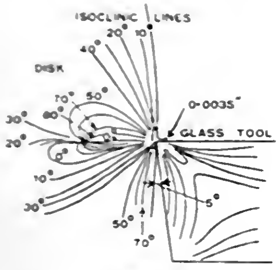

Fig. 5-b

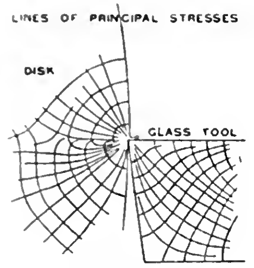

Fig. 5-c

Fig. 5-b Lines Marking the Centers of the Black Bands in Plate

Fig. 5-c Lines Along the Direction of Principal Stresses

This information with regard to directions of stress is complete, since every part of both tool and work is swept over by the black bands during the rotation of the prisms. For convenience, however, it is generally preferable to show this information in a different manner by lines which run along the direction of principal stress. Some of these are shown in Fig. 5-c and are derived from the black bands by a simple geometrical process.

As regards the intensities of the stresses, it is pointed out that the color effect obtained depends on the value of the difference of their intensities at a point and the method to separate such two stresses as p and q, Fig. 4, is described in the original article.

It is said that the color photograph has given a considerable amount of information on the behavior of cutting tools. Thus, in the color photographs very near to the point of the tool an intensely black spot is found which varies slightly in position in regards to the running positions. It forms in part a good qualitative index of the steadiness of the running and of the uniformity of the cutting action. It is also of interest to note that there is a black patch in the shaving immediately above the tool, which remains stationary in time but not in position, as, although the shaving is intensely colored after leaving the tool, the black patch disappears (not, however, with a badly ground tool).

The general appearance in polarized light of a disk under the action of a cutting tool varies with a shape of the tool. Thus, a tool with an edge finished by grinding in the usual way and an angle of from 45 to 60 deg. produces an action quite different from one with a similar edge but finished on a stone as perfectly as possible.

Considerable differences are also noticed with a change of speed when a sufficiently sharp or properly formed cutting tool is used, so that color pulsations are avoided.

The measurement of the stresses in the neighborhood of the tool was not found to present any great difficulty.

Stress distribution in the cutting tool was also investigated, but it does not appear that definite conclusions have been arrived at. (Paper before the *Institution of Mechanical Engineers*, abstracted through *The Engineer*, vol. 133, no. 3462, May 5, 1922, pp. 503–505, illustrated, *d*)

POWER-PLANT ENGINEERING (See Engineering Materials)

Distilling Tar from Coal While Burning Under Boilers

Distilling Tar from Coal While Burning under Boilers, Dr. Alfred Gradenwitz. German engineers are finding it worth while to extract the low-temperature tar from coal used for power and heating purposes. One of the three methods of doing this is by burning the fuel in a grate furnace and distilling shaft arranged to combine the burning and distilling processes. This method has been worked out by one of the engineers of the Pintsch Company of Berlin, and employs a type of furnace shown diagrammatically in Fig. 6.

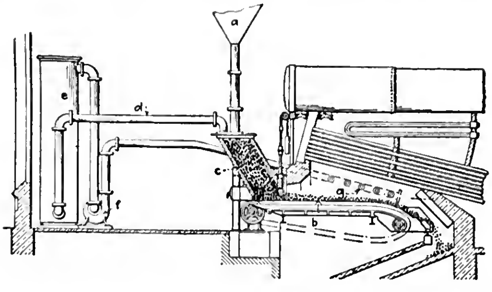

Fig. 6 Combined Furnace and Distillation Plant for Recovering Tar from Coal Burned under a Boiler

Before the coal in the bunker *a* reaches the grate *b*, it passes through a distilling shaft *c*. The coal in the bottom of this shaft is heated by the glowing coals on the front of the grate, and some of the gases given off are drawn through the pipe *d* into the extraction plant *e* by the pump *f*. The permanent combustion gases are then returned through the burners *g* into the furnace, the tar, ammonia, etc., having been retained in the extraction plant.

Not all the gases extracted from the coal are drawn through the distillation shaft and the operation is limited to a relatively small amount of combustion gases of which, moreover, the greater part are reduced to carbon monoxide and hydrogen in the lower part of the shaft by coming in contact with the incandescent carbon at the bottom.

This method was tried out for several months at the municipal electric works near Berlin. The equipment included a Steinmuller inclined water-tube boiler of about 5400 sq. ft. heating area, with preheating and superheating and two traveling grates with a total surface of about 183 sq. ft. Two tests were run on this boiler, each lasting about 30 hr., one being without the tar plant and one with it. The percentage of fuel heat represented in evaporated steam was 76.8 in the former case and 77.5 in the latter. The gain in evaporation was apparently insignificant, but the dry-tar output was 2.25 per cent, representing 4.3 per cent of the heat in the fuel and bringing the total efficiency of the boiler and distilling plant to 81.8 per cent.

A comparatively small amount of distillation gas was drawn off in

this test, but more recently, in the same installation, the tar output was raised to 4.53 per cent; and since that is twice 2.25 per cent, it should represent approximately twice 4.3, or 8.6 per cent of the heat in the fuel, indicating an overall efficiency of perhaps 86 per cent. (*Power*, vol. 55, no. 25, June 20, 1922, p. 970, 2 figs., *d*)

POWER-PLANT ENGINEERING

Condenser Doors

Condenser Doors. Hick, Hargreaves & Co., Ltd., England, have devised a special arrangement for facilitating the opening of condenser doors when they are formed in two parts and carried on a central hinged pin.

The principal characteristics of the scheme are the provision of means whereby the joint between one half of the door and the condenser can be broken independently of the other joint between the other half of the door and the end of the condenser. In Fig. 7 the two parts of the complete door are shown at *A* and *B* and each part is carried on a hinge *C* and *D*. To open either part of the door the joint bolts *E* and the nuts on the studs at *G* are removed and forcing screws *F* are then employed in the ordinary way for breaking the joints. Difficulty however, is liable to be met with in opening the doors *A* and *B* on account of their being close to the central bar on the end of the condenser, any jointing material at the joint *H* being scraped off, while the door is being swung open and again when it is closed.

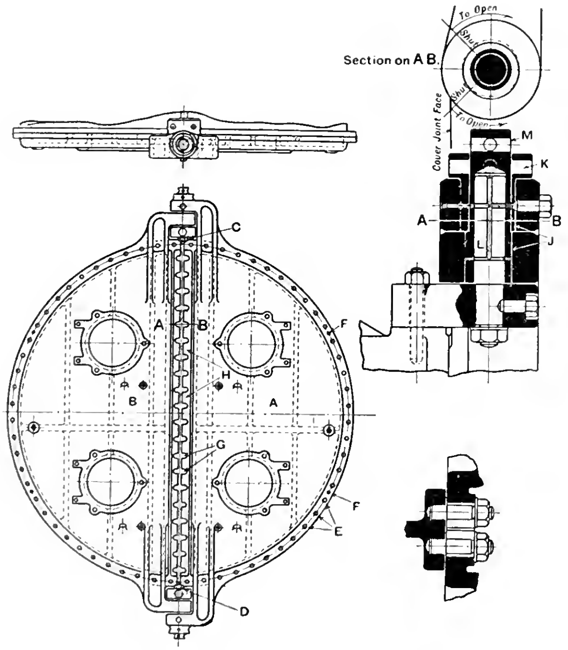

Fig. 7 Arrangement of Doors for a Continuous-Service Condenser

To overcome this difficulty, however, each of the hinged doors is provided with an eccentric bush *J*, which enables each door to be forced away from the facing on the end boxes. This is done in one case by inserting a tommy bar in the holes *K* of the bush *J*, and in this manner the bush is rotated eccentrically with respect to the main pin *L* and the door is moved away in the desired manner, thus giving the requisite clearance between the door and the facing and enabling the door to be swung round clear of the box facing. When closing the door the operations are repeated in the reverse order. In this way the jointing material along the joint *H* is left intact and the pressure is applied by the eccentric bushes prior to the nuts *G* being put on the studs. When it is desired to open the other door, a tommy bar is placed in the holes *M*. The door can then be swung open independently of the adjacent one. Doors of this type are usually employed in connection with surface condensers using dirty circulating water, as one half of the condenser can be cleaned without entirely shutting down the machine.

Continuous surface condensers are also made by Brown-Boveri. The cooling water flows through the condenser in two streams, the water chambers being divided by a vertical wall and the inlet and discharge branches are duplicated, but the steam space is not divided. When both sides are working the condenser differs from the ordinary type only in the manner in which the water flows through it and also in that the air is ejected from both sides. In order to clean half of the condenser it is merely necessary to close the inlet and discharge valves on the portion it is desired to put out of action and drain off the water which remains in that section. The reduction of vacuum which occurs in consequence of half of the condenser being put out of commission is stated to be only about 3 per cent of full load, while at half-load it is somewhat higher than that attained with both the sections in use under load conditions.

The two-part condenser enables cleaning to be done without putting the turbine out of service. (Abstract of a part of a serial article entitled "Developments in Power Station Design," *The Engineer*, vol. 133, no. 3461, Apr. 28, 1922, pp. 457–459; the abstracted part pp. 458–459, illustrated, *d*)

Pulverized-Coal Burning in a Large Station

Largest Station Using Pulverized Coal. Description of the Lakeside Station at Milwaukee, laid out for an output of 200,000 kw., of which 40,000 kw. is installed.

One of the most interesting features is that the plant is designed to use pulverized coal exclusively, this decision having been arrived at on the basis of experiments in the use of this fuel which the company had been conducting at its Oneida Street power plant for over two years.

Pulverized fuel is fed to the furnace by screw feeders from overhead storage bins. Six out of the eight furnaces are fed from the top with the coal discharging vertically downward, while for experimental purposes the other two were fitted with horizontal burners. Recently, however, horizontal burners were discarded and in all furnaces the vertical method of feeding fuel was employed. The furnace volume is approximately 7000 cu. ft. In certain tests in which capacities ranged from 137 to 236 per cent of rating, the fuel burned per cubic foot of combustion space varied from 0.85 to 1.62 lb.

In the coal-preparation plant the belt conveyor leading to the pulverizing-plant building discharges on a reversible cross-belt conveyor of the same width which distributes the crushed coal to three parallel conveyors equipped with automatic trippers; these latter conveyors pass over the green-coal storage bins in the pulverizing building and maintain an even supply in them. Under the bins run three 12-in. screw conveyors arranged to discharge through automatic scales into three indirect-fired rotary driers 5 ft. 6 in. in diameter and 40 ft. long.

These driers reduce the moisture in the coal by means of hot gases from individual furnaces fired with pulverized coal. Each drier is capable of reducing the moisture content in 10 tons of coal an hour from 10 to 12 per cent.

After being exhausted from the drier, the gas is blown through collectors 14 ft. in diameter which recover any coal dust it carries away in passing through the agitated coal. The hot dry coal is next transported to the mill feed bins by means of parallel arrangements of 16-in. screw conveyors and continuous bucket elevators, each set having a capacity of 60 tons an hour. The idea is to provide spare capacity in case of breakdown. The mills are of the pulverized type, utilizing the air-separation system, and driven by 100-hr. motors their total hourly capacity is 48 tons. They pulverize to a fineness that 75 per cent will pass through a 200-mesh screen and 90 per cent through a 100-mesh screen. With the air-separation method no screens are needed. An exciter driven by the mill shaft draws a current of air over the bull ring in the mill and the velocity of this air is such that it picks up only those particles that have been ground to the necessary fineness.

As the quantity of ash from pulverized-fuel furnaces is small and the ashes fine, it is easily conveyed by steam-jet ash conveyors.

From tests made by the U. S. Bureau of Mines at the plant it would appear that efficiencies of blower and superheater were obtained ranging from 79.8 to 85.2 per cent and efficiencies of boiler, superheater and economizer ranging as high as 89.6 per cent with a minimum of 85.0 per cent. These high efficiencies are credited to the fact that with powdered coal the proper ratio of air to coal can be maintained easily, so that there is small loss due to excess air and practically no loss from incomplete combustion and combustible in refuse. (*Power*, vol. 55, no. 16, Apr. 18, 1922, pp. 604–610, illustrated, *d*)

PUMPS

A New Form of High-Vacuum Automatic Mercury Pump, H. P. Waran. The pump is based on a modified Sprengel action. It works automatically, the mercury being removed from the lower to the upper reservoir mixed with a current of dry air which is sucked through a side tube by a filter pump. The defects of design of former types of pump are discussed, their inefficiency at low pressures explained, and suitable simple remedies suggested. The introduction of an intermediate reservoir in the middle of the fall tube, kept automatically exhausted by the Sprengel action in the lower fall, allows the upper half to exert a positive exhaustion for every pellet of mercury falling down, even at the lowest obtainable pressure. The absence of compression in the first fall enables the maximum bore to be used for the fall tube; and hence speeds and efficiencies of exhaustion comparable to those of a Gaede pump are obtainable, though less than a pound of mercury is required to operate the pump. (*The Physical Society of London*, vol. 34, pt. III, Apr. 15, 1922, pp. 120–125, 2 figs., *d*)

RAILROAD ENGINEERING

Nickel-Chrome Steel Railway Couplings. Description of couplings made by a British concern and tested at the Sheffield testing works. The test was a destruction test, the specified minimum load being 100 tons. In addition to being able to withstand this degree of tension, the nickel-chrome coupling, apart from actual fracture, will carry about twice the tonnage of straight carbon-steel couplings without permanent distortion, the elastic limit being 85 per cent of the ultimate strength. The weight is 10 lb. less than that of the carbon-steel castings.

The production of these couplings became possible because of the wide experienced gathered during the war as to the best heat treatment to insure uniformity and soundness. (*The Engineer*, vol. 133, no. 3464, May 19, 1922, p. 562, 1 fig., *ed*)

Ramsay Condensing-Turbine Locomotive. A brief reference to this locomotive was made in Mechanical Engineering (June, 1922, p. 390). It uses the main turbine of the impulse pressure compounded multi-stage type connected through a flexible coupling to a three-phase generator capable of sustaining a 25 per cent overload for half an hour. This generator is separately excited by an auxiliary turbine-driven direct-current generator. The generator supplies power to four three-phase slip-ring motors arranged in two groups on the front and rear parts of the locomotive, respectively. The power is transmitted from a crankshaft to which each pair of motors is geared to six driving wheels on both the forward and rear units of the locomotive, this being done by coupling rods in the ordinary manner.

The rear unit which replaces the usual tender contains the coal bunker and cooling-water tank, as well as the condenser and its accessories. The condenser is of the evaporating type, supplied with air by a fan at the rear of the engine. This fan is illustrated in the original article. The principal dimensions and characteristics are also given in the original article. (*Railway Review*, vol. 70, no. 19, May 13, 1922, pp. 667–668, 2 figs., *d*)

Effect of Tonnage Rating and Speed on Fuel Consumption, J. E. Davenport. The author claims that relatively heavy slow-speed trains are the most economical. Taking a modern Mikado-type locomotive, he plots a coal vs. horsepower curve illustrating the increase in efficiency in locomotive performance as the horsepower output increases to a point near 1400 hp., and the decrease as it increases beyond that figure. On the same sheet he plots resistance vs. speed curves, illustrating the decrease in hauling efficiency as expressed in car resistance in pounds per ton as the speed increases and the car weights decrease.

From data obtained in tests by the Pennsylvania Railroad and at the University of Illinois he finds that at the point of maximum horsepower output the coal consumption increases most rapidly with each unit of power produced.

Data of other tests on the Pennsylvania Railroad are used to establish the importance of the empty-car movement in fuel-economy programs and the importance of proper loading of trains. His general conclusion is that the handling of heavier cars and heavier trains and elimination of excessive speeds will greatly assist in reducing the fuel bills. (Paper before the 11th annual convention of the International Railway Fuel Association, abstracted through *Railway Review*, vol. 70, no. 22, June 3, 1922, pp. 777–782, 10 figs., *p*)

Ljungstrom Turbine Locomotive. Description of a condensing-turbine locomotive recently placed in service on the Swedish State Railways. According to reports the locomotive has performed in a satisfactory manner and has shown great economy in fuel. Complete details of the construction are not yet available, but from photographs it would appear to be a radical departure from conventional locomotive design.

It is intended to displace the Pacific-type locomotives now in use in passenger service on the Swedish State Railways. Unlike ordinary locomotives, there is no driving machinery under the boiler. Instead it is supported by two trucks, the forward with two and the rear with three axles. The driving machinery is located under the tender unit, which also contains the condenser and the necessary fans for aiding in condensation.

The driving machinery consists of a high-speed turbine geared to the six-wheel-connected running gear which has drivers 58 in. in diameter and is located under the tender. The following arrangement is used for heating the air supplied to the furnace: The space between the mud ring and the ashpan is tightly closed and the air for combustion passes through a special air preheater under the smokebox where the temperature is raised by escaping gases from the smokebox. Draft is created by a fan propelled by a small turbine. A damper connected with the firebox door shuts off the draft when the door opens, thus preventing unnecessary cold air entering the firebox flues. (*Railway Age*, vol. 72, no. 22, June 3, 1922, pp. 1295–1296, 1 fig., *d*)

REFRIGERATION

Tests on Compound Ammonia Compression Refrigerating Systems

Compound Ammonia Compression, George A. Horne. An extensive article reporting tests on compound compression systems in two refrigerating plants. Because of lack of space only the major conclusions of this very interesting paper can be reported here.

The machines on which the tests were made are operated with two-stage intercooling in which a gas from the low-pressure cylinder passes through a tubular cooler cooled with well water, and from there into an intermediate receiver into which the high-pressure liquid from the condensers is discharged. The gas is thereby cooled to a temperature corresponding to the intermediate pressure and passes to the high-pressure cylinder; or the high-pressure liquid passes through the intermediate trap where it is cooled to a temperature corresponding to this pressure, and from there passes to the brine coolers. There are no water jackets used on any of the compressors; the liquefied ammonia passes from the ammonia receivers through double-pipe liquid coolers in which it is cooled by well water.

A complete heat balance of the refrigerating cycle is given in the original article.

The results of the extensive tests indicate the advantage of compound ammonia compression with a ratio of compression of six to one or above.

The intercooling by water is clearly demonstrated to be fundamental to the operation of compound compression systems. Where it is impossible to obtain water of a temperature of 60 deg. fahr. a

saving at this stage of the cycle would not be as great, but whatever water is available for condensing purposes there would be a substantial saving in the intercooler.

Among the things found in this test it was fairly established that the venturi meter for measuring liquid ammonia is a valuable instrument in computing capacity of refrigerating machines and may be used to advantage in the practical operation and control of refrigerating system.

Additional tests were carried on in which no liquid intercooling or injection was used, all liquid from the liquid coolers passing directly to the drying, cooling and intercooling between the two stages being accomplished with well water at 60 deg. fahr.

It was found that the operation without liquid intercooling or injection is substantially identical with the operation with liquid intercooling as far as compressor horsepower is concerned. As the chief argument for compound compression over simple compressing hinges on the matter of economy, it is important to determine the simplest and best method of constructing and operating compound compression systems. The author is convinced that any theoretical gain due to liquid intercooling, pressure reduction or injection is offset by losses resulting from handling from 10 to 15 per cent of the total ammonia circulated in the high-pressure side. The elimination of liquid intercoolers materially simplifies the layout of a compound compression system and decreases the first cost. He believes that even 80-deg. fahr. water through the intercooler with a 10-deg. range would hardly justify the installation of the intermediate liquid receivers. He comes to the conclusion that intermediate cooling and injection instead of being essential to compound compression is either entirely unnecesary or merely a refinement of slight merit, while water intercooling is indispensable.

Further tests were carried out by the author and are described in his paper printed in the May issue of the *A.S.R.E. Journal*.

In view of the practice sometimes employed of cooling the low-pressure discharge gas partially or entirely with liquid ammonia, the author has made several observations and comparisons in actual practice in which gas from the intermediate cooler cooled by water was delivered to the high-pressure cylinder with practically no additional cooling by ammonia, and also where additional cooling with ammonia was used he was unable to find any reduction in horsepower per ton in the tests made with this secondary cooling by ammonia. This is of importance, as the use of ammonia in gas cooling results in a reduction of tonnage. Actual calculations have shown that the saving in power due to cooling gas with ammonia is less than 2 per cent, while the reduction in available tonnage is over 5 per cent.

The tests have revealed the fact that in every instance more work was done in the low-pressure cylinder than in the high-pressure cylinder. In some tests over 40 per cent more work was done in the low-pressure cylinders. The author therefore believes (though he does not claim that it had been conclusively demonstrated) that equal work in the two cylinders of a two-stage ammonia compressor produces the lowest horsepower per ton of refrigeration.

He has deduced an empirical formula for determining the correct ratio of cylinder-displacement volumes for two-stage compressors. Without intermediate liquid cooling this is—

$$V = 0.9\sqrt{R}$$

where V = ratio of low- to high-pressure displacement volumes and R = ratio of absolute low suction to high discharge pressures. With intermediate liquid cooling,

$$V = \left[0.9\sqrt{R} - (0.005\,t - t_1)\right]$$

where t = temperature of liquid to intermediate receiver and t_1 = temperature of liquid from intermediate receiver.

For example, let $R = 9$, $t = 70$ deg., and $t_1 = 40$ deg. Solving, $V = 2.55$, which is the correct ratio of low- to high-pressure displacement volumes.

In applying this formula to a common summer ice-making condition, say, of 20 lb. per sq. in. gage suction and 185 lb. per sq. in. gage discharge pressure or ratio of absolute pressures of six to one, with 30 deg. cooling of the liquid, $V = 2.3$. The point might be made that a given cylinder ratio is correct only for one set of conditions, but the answer to that question is found in having a suitable arrangement of clearance pockets on the cylinders. This arrangement of clearance pockets should be such that the highest pressure ratio expected would be satisfied when all pockets are closed on the low-pressure cylinder during the season of heaviest load, which is usually when the condenser pressure is highest. It has been found that the pockets can readily be used to regulate cylinder ratios and at the same time allow reduction in capacity at the time such reduction is desired. The author suggests, for example, that if the maximum ratio of pressures expected requires a cylinder ratio of 2.6 to 1, that an arrangement of pockets should be provided to allow a reduction in cylinder ratios of about 1.8 to 1. (*A.S.R.E. Journal*, vol. 8, nos. 4 and 6, Jan. and May, 1922, pp. 245–296 and discussion pp. 296–307, and pp. 455–487, illus. *epA*)

Influence of Water-Jacket Cooling on Performance of Ammonia Compressors

Influence of Cooling Water Jacket on the Performance of Compression Refrigerating Machines, Dr. Eng. Walther Fischer. The purpose of this extensive investigation was to determine the influence of the cooling water jacket on the performance of the compressor used in refrigerating machinery. The compressor was operated either in the superheated or the wet state at four different vaporization and three different liquefaction temperatures and an approximately uniform speed of rotation. Fifty-four tests in six series were carried out and analyzed in a manner to bring out the influence of the compressor cooling jacket on the output of cold and power consumption, all of these tests being so arranged that the desired temperature relations and permanent state of operation could be maintained quite uniformly. It was found that in work with superheated steam, operation with cooling water was in every way more satisfactory and that both the output and indicated efficiency increased with the fall in the temperature of vaporization. The total losses of the cylinder of the machine were divided into the part which visibly appears in the diagram and the volumetric efficiency, and the invisible part which originates in the wall action at suction. It was found that jacket cooling makes the volumetric efficiency worse, but improves to a greater extent the wall coefficient so that the employment of a water jacket may be considered as being thoroughly justified.

For purposes of comparison two additional series of tests were carried out: one with a variable speed of operation of the compressor, and another with a variable vapor content in the suction chamber of the compressor. It was found that with an increase of speed of rotation the output and indicated efficiency within the region investigated rose constantly, while the volumetric efficiency remained practically stationary, so that the improvement of output was obtained exclusively through the increase in the value of the wall coefficient. The tests carried out with variable specific vapor content in the suction chamber showed the remarkable superiority of superheated vapor as compared with saturated vapor for refrigerating machinery, and, in particular, that at about 90 per cent the output increases more rapidly; then again begins to decrease slowly, and even at $x = 1$ does not yet reach its maximum. (*Forschungsarbeiten auf dem Gebiete des Ingenieurswesens*, published by the Verein deutscher Ingenieure, 1921, no. 244, 78 pp. and 25 figs., *e*)

Advantages of Certain Hydrocarbon Refrigerants

Some Properties of Hydrocarbon Refrigerants, H. D. Edwards. The increasing interest in refrigerating mediums, due principally to the development of chemical processes requiring temperatures not obtainable with present standard machines; to the desire to perfect the small automatic machine; and to the desire, during the war, of the Government to have developed a substitute for ammonia for refrigerating purposes, has caused a study of refrigerants little used or known and has hastened their commercial production.

The selection of a refrigerant depends upon many conditions, such as its vapor characteristics, latent heat, critical temperature, chemical action on materials and lubricants, deterioration, hazard in handling, danger to life, etc.

That the hydrocarbon gases are good refrigerants has been known for some time, and their first application is recorded in England in 1911. They have been used in this country for the past few years.

The hydrocarbon gases are non-poisonous and do not corrode any materials. They must be handled in the same manner as all other inflammable refrigerants.

The use of butane permits of higher suction pressures than are possible with ethyl chloride, and with propane can be mixed so as to give a positive suction pressure.

Due to the similar vapor characteristics, ammonia and propane may be used together in the same equipment, and a change from one to the other may be made by charging the desired gas as make-up.

The density of propane is 2.6 times that of ammonia. While it takes 2.6 times as much propane to charge the system, it takes 2.6 times as long for it to leak out. In addition, propane will not deteriorate or break down under any conditions possible in the system. The density of propane is 50 per cent greater than that of air.

Standard fittings and valves used in air service may be used with propane as the refrigerant will not injure them.

Accurative comparative tests seem to be the only means of determining whether ammonia or propane has the larger net refrigerating effect under all operating conditions, for their value pound for pound seems to be practically identical.

Temperatures approximately 20 per cent lower than those obtainable with ammonia are being maintained with propane.

Due to the characteristics and low cost of CO_2, the application of ethane is necessarily limited to low-temperature work. Temperatures of —70 deg. cent. (—94 deg. fahr.) are being maintained with a standard CO_2 outfit using ethane as against a minimum of —50 deg. cent. with CO_2.

On account of the low discharge pressures resulting from the use of ethane, there is no more leakage than with CO_2, although the density of the former is the least.

The author is conducting comparative tests on the refrigerants mentioned, and is instituting an investigation to determine the unknown physical properties necessary to obtain complete data, particularly on the hydrocarbon gases. (*A.S.R.E. Journal*, vol. 8, no. 6, May, 1922, pp. 488–495, 5 figs., *de*)

SPECIAL MACHINERY

Visco Air Filter. Description of a new filter of British manufacture, intended chiefly for cleaning air supplied to turbo-alternators, blowers, compressors and ventilating plants. The filtering medium consists of innumerable short rings of very thin coppered-steel tubing of small diameter coated with a very thin film of "viscinol," a high-class mineral oil of special characteristics. It has a very high flash point and the temperature of the fire test is such as to render it practically non-evaporating and non-inflammable. This is very important as it is essential that there should be no possibility of oil vapors being formed at any temperature likely to occur in practice. At the same time the solidifying temperature is exceptionally low, so that the filter is not affected by frost. The oil is very viscous, which prevents it from running. The cells which contain the filtering ring are made in standard sections about 20 in. sq. and 3 in. deep and are stamped out of steel in one operation. The filtering rings lie quite irregularly in the cell and offer a very large surface to the air passing through, 1 cu. ft. of rings representing about 300 sq. ft. Due to their irregular position the air is deflected from its straight course a great number of times without at the same time meeting with any undue resistance, which varies from 4 mm. to 8 mm. (0.16 to 0.32 in.) of water according to the time the filter has been in use. After several months of operation the filter is cleaned by either hot soda water or steam, subsequent to which the cells are recoated with viscinol by simple immersion. (*The Electrical Review*, vol. 90, no. 2321, May 19, 1922, p. 717, 3 figs., *d*)

SPECIAL MACHINERY

Wire Saws for Slate and Marble Cutting. Description of products of British manufacture. The cutting wire (helicoidal) in the plans described is continuous and is passed from place to place by means of guide pulleys. The wire travels at about 12 miles per hour. It is made in lengths of from 220 to 880 yd., sometimes more, and in three diameters, 4 mm., 5 mm. and 6 mm., the lighter-gage wire being employed for yard sawing and the heavier for quarry work. In a large working the cutting wire is sometimes driven by a pulley fixed on a countershaft which may drive one or more lines of cutting wire each with its own friction clutch so that each can be worked independently of the other. The wire saw is a useful and economical machine, being cheap to operate, requiring little horsepower, and only occasional attention to see that sand and water are kept fed into the cut. They have been developed primarily for marble working, but can be easily adapted to slate cutting. Attempts to use them for sandstone cutting did not apparently turn out well, because of the excessive wear on the wire. The original article describes the details of their installation. (*The Quarry and Surveyors' and Contractors' Journal*, vol. 27, no. 303, May, 1922, pp. 181–183, 4 figs., *d*)

STEAM ENGINEERING (See Thermodynamics)

Nozzle Losses in Compound Steam Turbines

Nozzle Losses in Compound Turbines. Certain continental engineers have claimed that the higher the steam speed, the more efficient the turbine. This theory is based on the fact that, taking any given nozzle, the higher the velocity of efflux, the less proportionately is the energy wasted in friction. This view is supported also by practical experience.

In a paper published in 1919 in the *Zeitschrift des Vereines deutscher Ingenieure*, Dr. R. Fluegel suggested that the explanation might be found in the fact that a dimensional factor is involved in the resistance to flow of fluids through similar channels.

If in a steam turbine the steam speed be diminished larger nozzles will be required to pass a given quantity of steam, and Fluegel suggested that in this increase of dimension was to be found the explanation of the fact that in practice turbines with low steam speeds appear to be quite as efficient as turbines with high steam speeds.

By the principle of dynamic similarity established by Stokes in 1850, the resistance R per square centimeter of rubbing surface is given by the relation

$$R = \rho v^2 \phi \left[\frac{\upsilon}{vd}\right]$$

where ϕ denotes some function of the expression in brackets, ρ the density of the fluid in grams per cubic centimeter, v the velocity of flow in centimeters per second, υ the kinematic viscosity of the fluid, and d the diameter of some other typical parameter of the waterway.

From experiments analyzed by Prof. C. H. Lees (*Proc. Roy. Soc.*, 1914) it would appear that at low velocities the plotted points fall on an entirely different curve to that which represents them at higher velocities of flow. In the former case the flow is linear in character, while at higher velocities it is turbulent and there is a region of transition between the two curves in which observations plot erratically and repeat experiments do not necessarily yield concordant results. This confirms the truth of the law of dynamic similarity, which may be therefore applied to Dr. Fluegel's program.

For smooth nozzles the author derives the formula for the energy dissipated per unit mass passed per second, as follows:

$$\frac{C}{2} \times v^2 \times \left[\frac{\mu d}{m}\right]^n$$

where C is a constant, m the mass passed per second, μ the viscosity of the fluid, n a small fractional power of the order of 0.1 to 0.2, and d the diameter of the nozzle. In the case of the nozzle, v denotes the actual velocity attained. He shows further that the percentage loss in a nozzle is proportional to $(\mu d/m)^n$.

In a turbine in which the steam speed is high the value of d will be less than in a turbine passing the same mass of steam per second but having a greater number of stages. Hence if n be, as it is natural to suppose, a positive number, the nozzle losses will be less in the high-speed turbine, and the fact that this is not supported by experience must be sought elsewhere than in the dimensional factor suggested by Dr. Fluegel.

Actual experience may be explained in part by the fact that the more stages in the turbine, the higher the reheat factor; but cal-

culation shows that the gain due to this circumstance is very small. The slow-speed turbine has, however, another advantage in that the losses by disk friction and the like in a slow-speed turbine of given output are smaller proportionately than in a machine with high blade speeds. In the foregoing the value of n has been left indeterminate. In the case of parallel pipes it is known to be a small fraction, but its value for nozzles does not seem to have been investigated. Such a research would be of interest and could be carried out with comparatively simple apparatus, using water as the fluid. The viscosity of water is about four times as great at 0 deg. cent. (32 deg. fahr.) as it is at 50 deg. cent. (122 deg. fahr.), so that a fair range of values would be readily available, and from the principle of dynamic similarity the coefficients found for water would also apply to steam.

From this the author proceeds to show that, in accordance with the theory of dynamic similarity, when any viscous fluid flows through a channel the frictional resistance per square centimeter of wetted surface must be expressible in the form

$$\rho v^2 \phi \left(\frac{v}{vd}\right)$$

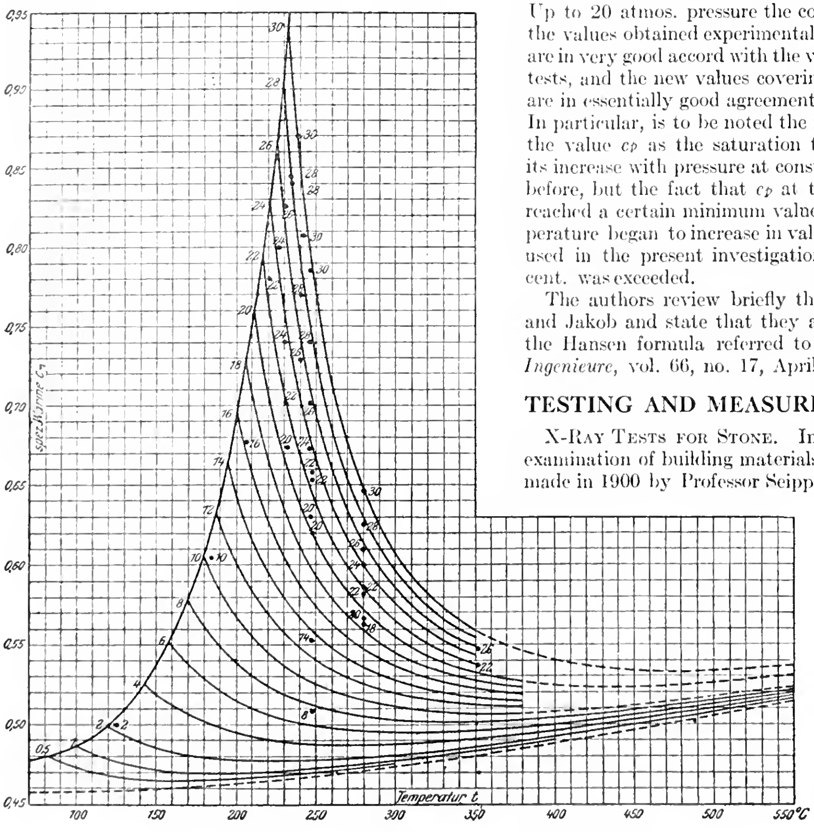

Fig. 8 Specific Heat (c_p) Isobars in the c_p-t Diagram
(Ordinates; *spez. Waerme* = specific heats.)

THERMODYNAMICS

Specific Heat of Superheated Steam for Pressures from 20 to 30 Atmos. and for Saturation Temperatures up to 350 Deg. Cent., Oscar Knoblauch and Erwin Raisch. Description of tests carried out in the Laboratory for Technical Physics at the Munich Technical High School, where so many important previous investigations on the thermodynamic properties of steam have been carried out, among others by the first of the authors of this paper. The present investigation extends the range of previous research to the higher pressures and temperatures indicated in the title.

The results obtained in this investigation are in good conformance with those previously obtained for the lower ranges and further confirm previous observations to the effect that the specific heat increases with the pressure, but decreases with the increase of temperature beginning with the temperature of saturation. In the original article the results are given in a number of tables in addition to which one figure gives the c_p isobars in the c_p-t diagram. (Fig. 8).

In these figures the abscissas are temperatures and the ordinates are c_p values obtained experimentally and by interpolation reduced to whole numbers. Through the points thus obtained curves have been drawn connecting points of equal pressure. For the sake of completeness isobars for pressures below 20 atmos. were plotted as obtained from previous investigations. The part of the curve drawn in full line covers the region determined experimentally; the broken-line curves have been obtained by means of extrapolation.

The curves are based on an equation by A. Hausen (apparently unpublished) which expresses c_p as a function of temperature and pressure. Its constants have been determined from observed values by the method of least squares. From Fig. 8 it would appear that the deviation of the points experimentally obtained from the analytically determined curves is in general less than one per cent. Up to 20 atmos. pressure the comparison between the isobars of Fig. 8 and the values obtained experimentally and given in a table in the original article, are in very good accord with the values previously obtained in the the Munich tests, and the new values covering the region from 20 to 30 atmos. pressure are in essentially good agreement as to general behavior with the old values. In particular, is to be noted the marked increase at the higher pressures in the value c_p as the saturation temperature is being approached, as well as its increase with pressure at constant temperature. This has been observed before, but the fact that c_p at the lower pressures and rising temperature reached a certain minimum value, and then with a further increase of temperature began to increase in value, was observed at the higher temperatures used in the present investigation only when the present limit of 350 deg. cent. was exceeded.

The authors review briefly the latest work of Hencky, Plank, Eichelberg and Jakob and state that they are at present engaged in further work on the Hansen formula referred to above. (*Zeitschrift des Vereines deutscher Ingenieure*, vol. 66, no. 17, April 29, 1922, pp. 418–423, 9 figs., *etA*)

TESTING AND MEASUREMENTS

X-Ray Tests for Stone. In Germany attention is being given to the examination of building materials by means of X-rays. Investigations were made in 1900 by Professor Seipp; and more recently Prof. L. Freind and the late Prof. A. Hanisch have made some extensive researches on the action of X-rays on slates, both natural and artificial. Twelve kinds of clay slate were examined, and various structures were observed in the X-ray diagrams, giving clear indications as to the uniformity and arrangement of the slaty substance. The most conspicuous advantages of the X-ray method as compared with other testing processes are its cheapness and rapidity, as well as the ease with which it can be used without any elaborate or difficult preparation, independently of any chemical analysis or the use of transparent microscopic sections, on large samples as well as on small amounts of material. Other kinds of building material, listed in the complete article, showed interesting variations in permeability to X-rays. (Editorial article in *Quarry and Surveyors' and Contractors' Journal*, vol. 27, no. 303, May, 1922, p. 167, *g*)

CLASSIFICATION OF ARTICLES

Articles appearing in the Survey are classified as *c* comparative; *d* descriptive; *e* experimental; *g* general; *h* historical; *m* mathematical; *p* practical; *s* statistical; *t* theoretical. Articles of especial merit are rated *A* by the reviewer. Opinions expressed are those of the reviewer, not of the Society.

ENGINEERING RESEARCH

A Department Conducted by the Research Committee of the A.S.M.E.

Research Résumé of the Month

A—Research Results

The purpose of this section of Engineering Research is to give the origin of research information which has been completed, to give a résumé of research results with formulas or curves where such may be readily given, and to report results of non-extensive researches which in the opinion of the investigators do not warrant a paper.

Corrosion A1-22. Deterioration of Structures in Sea Water. Since 1916 a series of investigations into the deterioration of structures of timber, metal and concrete in sea water has been undertaken by a committee of the Institution of Civil Engineers, London, with the aid of a grant from the Department of Scientific and Industrial Research. The first report of the committee was published in 1920, and it is now considered advisable to issue the present interim report which deals with work subsequently undertaken.

The report is arranged under the following headings:

Report on deterioration of structures exposed to sea action. (Admiralty.)

Report on the action of worms in the water of the Mediterranean round Malta.

Memorandum dealing with condition of materials of construction of docks, etc., exposed to the action of sea water. (Portsmouth.)

Report on deterioration of structures exposed to sea action. (Devonport.)

Report on the preparation of the various steel and iron specimens for the Committee on Sea Action of the Institution of Civil Engineers. (Sir R. Hadfield).

Report on the work done for the Committee on Sea Action, 1920–21. (J. N. Friend.)

Report on the investigation of the protection of timber against teredo attacks. (G. Barger.)

Report of work done at the Marine Biological Station, Plymouth, July 1 to September 18, 1920. (C. R. Harington.)

Abstracts from Bulletin of the Public Works of the Navy. (United States.)

Abstracts of reports received from correspondence.

Address H. M. Stationery Office, Imperial House, Kingsway, London, W. C. 2. Price 2s. 8d.

Electrical Communication A1-22. Radiation from Special Form of Antenna. The Bureau of Standards has just published a paper giving the theory of the radiation from an antenna consisting of 2 horizontal coils. The area within which the signal is heard, and the point at which it is most intense, are discussed. The results of these investigations are given in Bureau of Standards Scientific Paper No. 431, The Field Radiated from Two Horizontal Coils, which may be obtained from the Superintendent of Documents, Government Printing Office, Washington, D. C., at 5 cents a copy.

Fire Prevention A2-22. Fire Tests of Loaded Timber Columns. See *Framed Structures A1-22.*

Framed Structures A1-22. Fire Tests of Loaded Timber Columns. In an address delivered at the "Building Officials Conference" Mr. T. F. Laist of Chicago gave the results of a series of tests recently carried on by the National Board of Fire Underwriters. The fire-endurance classification of a nominal 12-in. by 12-in. select structural longleaf Southern pine or Douglas fir column of ordinary length, may be more than doubled if the ends are adequately protected against fire. It appeared from these tests that instead of a thirty-five minute endurance rating, a one and one-quarter hour rating may safely be given provided the steel caps as ordinarily used are insulated or a concrete cap is used, thus preventing the crushing and brooming of the wood fibers under the cap and causing failure long before the sectional area of the column is otherwise reduced to the point of failure. It was also shown that such adequate fire protection for the ends of timber columns in mill construction buildings may be obtained by reinforced-concrete post caps such as were used in these laboratory tests. While such caps have been successfully devised for experimental purposes, so far they have not been commercially produced, nor have such tests been made upon caps supporting girder loads.

While in this series of tests no experimental work was done with steel or cast-iron caps, it is apparent that consideration of the results obtained would suggest that adequate insulation for the ends of timber columns may be obtained from the installation of fireproof materials on the exposed faces of standard steel or cast-iron post caps. The tests also verified the greater superiority in fire resistance of timber construction to unprotected steel or cast-iron framing. Address Theo. F. Laist, 1613 Harris Trust Building, Chicago, Ill.

Fuels, Gas, Tar and Coke A10-22. Smokeless Fuel for Salt Lake City. In a brief but satisfactory way Messrs. G. St. J. Perrott and H. W. Clark have prepared a report on their investigations on this subject. This report is known as Bureau of Mines Serial No. 2341. It is a consideration of the practicability of by-product coking of Utah coals for supplying smokeless fuel to domestic consumers of Salt Lake City. The paper reviews briefly the work of the senior author and others in connection with the experimental side of low-temperature coking of Utah coals. The economic feasibility of supplying the entire domestic demand of Salt Lake City with carbonized smokeless fuel is considered from several viewpoints. The discussion includes a consideration of high-temperature and low-temperature carbonization in connection with the character of the coke and by-products produced, and their suitability for disposal on the Salt Lake City market.

Two of the four conclusions reached by the authors are interesting. (1) While the coke and by-products of a low-temperature carbonization plant would probably find a readier market than those of a standard high-temperature plant, neither plant would be a commercial success without protective legislation. A semi-experimental 100-ton plant should be able to operate with a smaller differential between the price of coal and coke due to more favorable disposal of the smaller volume of by-products. (2) No single solution for the domestic smoke nuisance appears available. Means which should be considered for alleviating the nuisance are (1) sale of the available supply of gas-house coke; (2) briquetting of coke breeze from the beehive ovens at Sunnyside for domestic fuel; (3) burning of powdered coal where feasible; (4) installation of semi-experimental 100-ton plant for low-temperature carbonization; and (5) continuation of educational campaign to teach domestic consumers proper methods of firing the native coal. Address Reports of Investigations, U. S. Bureau of Mines, Department of Interior, Washington, D. C.

Fuels, Gas, Tar and Coke A11-22. Preparation and Uses of Tar and its Derivatives. The importance of tar as a commercial product has been emphasized during the past five or six years more than ever before. In that time, the market for tar and its products fluctuated in an unprecedented way, because of the war and other conditions, with the result that the production of tar and tar products increased greatly. A large proportion of the increase is due to the installation of by-product coke ovens, which are fast replacing the beehive ovens, from which tar and other by-products are not recovered.

This paper discusses the uses to which some of the various tars are put and shows briefly the usual methods of working up tar into some of its simple or easily prepared derivatives, for which a market can generally be found. Although coal tars are given chief consideration, the properties and characteristics of water-gas tar are mentioned, for the reason that this tar is often produced in plants where coal tar is made, the mixed tar being collected and marketed, and for the further reason that the presence of water-gas tar in some coal-tar products is specifically interdicted by commercial specifications. This publication is not a handbook on tar distillation, for that subject can hardly be covered adequately in such limited space, but is published by the Bureau of Mines as a general treatise on the utilization of tar. Address Superintendent of Documents, Government Printing Office, Washington, D. C., asking for Bureau of Mines Technical Paper 268. Price 15 cents.

Metallurgy and Metallography A2-22. Metallographic Etching Reagents. II—For Copper Alloys, Nickel, and the Alpha Alloys of Nickel. This article constitutes the second part of the general investigation of metallographic etching reagents in progress at this Bureau. It is closely related to the one already published on copper in the methods employed and results obtained. The following materials were used: Copper alloys, including brasses, bronze and aluminum bronze; nickel and the alpha alloys of nickel, monel metal, cupronickel and nickel brass.

Experimental results are given to show the importance of films in producing contrast in etching. Oxide and sulphide films were used, and it was shown by separating the etching and the filming operations that films varying in thickness on the individual crystals are produced by certain reagents and give rise to "contrast." The better-understood methods for producing contrast by a differential roughening of the crystals upon etching is also illustrated.

The alpha copper alloys closely resemble copper in their general behavior upon etching and in the character of the results produced. The addition of tin to brass appears to render it slightly less responsive to etching reagents than the same alloy without tin; aluminum bronze in the rolled condition was the most unsatisfactory of the copper alloys examined to etch. A series of copper-zinc alloys representative of all the types of structure in this series was examined. The alloys rich in zinc resemble this metal in their etching characteristics more than they do the copper-rich alloys, in that highly oxidizing etching reagents do not appear to be necessary for the successful etching of the alloy.

Nickel, particularly when of high purity, is etched with considerable difficulty. Oxidizing acids, such as nitric, and acids to which strong oxidizers had been added were found effective for a quick etching.

For producing a contrast etch-pattern with freedom from pitting, a long immersion in concentrated hydrochloric acid was found to give excellent results.

Of the alpha-nickel alloys examined, monel metal and cupro-nickel were found to resemble nickel in their etching properties, though they etched more readily. The nickel brasses (nickel silver) resemble the alpha-copper alloys in many respects and were readily etched by the reagents used for the brasses and bronzes.

This report was prepared by H. S. Rawdon and Marjorie G. Lorentz of the Bureau of Standards and is known as Scientific Paper No. 435. For copies address Superintendent of Documents, Government Printing Office, Washington, D. C. Price 15 cents.

Petroleum and Allied Substances A5-22. Evaporation of Petroleum. Bulletin 200 by J. H. Wiggins of the Bureau of Mines. In 1919 the United States was threatened with a shortage of gasoline. In spite of this well-known fact, a detailed field investigation has shown that in one stage only of handling crude oil the volume of gasoline that evaporates is equal to one-thirtieth of the country's yearly gasoline production. This loss occurs during the few days that the oil is stored on the leases before being taken by the pipe line, and in 1919, in the Mid-Continent field alone, it amounted to 122,100,000 gallons. Large as it is, it is only a part of the loss on the lease. Investigation has further shown that the gasoline in crude oil evaporates from one-half to six-tenths as rapidly as the same gasoline after being distilled and stored, all evaporative conditions being the same.

In accordance with its purpose of seeking to conserve mineral resources, the Bureau of Mines investigated the loss of gasoline by evaporation in the storage and handling of petroleum. Inasmuch as most producers had not decided that their losses justified corrective measures and no evidence was available on the comparative losses in various stages of handling the oil, the investigation was limited to determining by experiment and observation the nature and magnitude of evaporation losses, where the greatest losses are, and the factor controlling evaporation. The results of the investigation, as presented in this report, indicate that losses from evaporation are so large that they should receive serious consideration at once by the industry, which should make every endeavor to reduce them to a minimum. The Bureau of Mines is now making a supplementary study of methods of reducing these loses.

This bulletin has three parts: First, a general discussion of the problem and the methods of attack; second, volumetric losses during various stages of handling and in various kinds of storage; third, scientific data on the evaporation of petroleum. Address Superintendent of Documents, Government Printing Office, Washington, D. C.; price per copy, 20 cents.

Petroleum and Allied Substances A6-22. The Analytical Distillation of Petroleum and its Products. Fractional distillation is the most important process in the commercial refining of petroleum. The same procedure, conducted on a small scale, is the basis of a number of analytical methods of wide application in the petroleum laboratory. The Bureau of Mines has studied apparatus and procedure for the distillation analysis of petroleum, and this report is presented as a record of developments up to the present time. The work is incomplete, but the extensive information that has been obtained to date is made available as a guide in handling the laboratory-distillation problems. Address Superintendent of Documents, Government Printing Office, Washington, D. C., and ask for Bureau of Mines Bulletin 207. Price 15 cents.

Petroleum and Allied Substances A7-22. Methods for Testing Petroleum Products. The methods included in this handbook are used officially in the routine testing and inspection of petroleum products bought under Federal specifications. They supersede similar methods published in Bulletins 1 to 5, inclusive, of the Committee on Standardization of Petroleum Specifications. This set of testing methods, known as Bureau of Mines Technical Paper 298, was prepared by the Technical Committee on Standardization of Petroleum Specifications and was adopted by the Interdepartmental Petroleum Specifications Committee, Address the Superintendent of Documents, Government Printing Office, Washington, D. C. Price 10 cents.

B—Research in Progress

The purpose of this section of Engineering Research is to bring together those who are working on the same problem for coöperation or conference, to prevent unnecessary duplication of work and to inform the profession of the investigators who are engaged upon research problems. The addresses of these investigators are given for the purpose of correspondence.

Corrosion B4-22. Resistance of Chromium Steels to Acid Corrosion. Tests of the resistance of chromium steels to acid corrosion have recently been completed, and a comparison of the results obtained shows that the relative resistance of a steel to the acid test is not necessarily a criterion of its behavior in other types of corrosion. Pure iron and the steels of low chromium content were found to be much more resistant to attack by hydrochloric acid than those containing considerable chromium. When corroded by water and air, the general order of resistance was reversed. It may be concluded, then, that the addition of chromium increases the rate of attack by hydrochloric and probably by other acids, although this may depend somewhat on the heat treatment which the steel has received. Specimens which had been hardened by suitable heat treatment were found to be considerably more resistant to acid attack than samples of the same composition in the annealed state. The addition of nickel is much more effective in reducing the intensity of the attack by acid than is chromium, since steels containing a considerable amount of this metal were found to be the most resistant to acid of all those tested. Specimens having a polished surface were found, almost invariably, to show a smaller loss in acid than those which were roughly ground.

This difference may be only apparent however, because although the measured surface of two specimens may be exactly the same, the one with a "ground" finish has a slightly greater area exposed on account of the minute grooves and ridges which make up the surface than has the polished specimen. Address Dr. S. W. Stratton, Director, Bureau of Standards, Department of Commerce, Washington, D. C.

Highways B3-22. Recent Developments in the Work of Highway Research. The recent progress in the study of this subject by the Advisory Board on Highway Research is outlined in a four-page pamphlet. Copies of this pamphlet may be secured by addressing the Secretary of the Division of Engineering, National Research Council, 29 West 39th Street, New York.

The subdivisions of the subject discussed are: Design of Stiff Slabs, Materials, Traffic Studies, and Economics. It is also recorded that four new committees of the Advisory Board have been authorized to take up investigations of the following subjects: Highway Finance, Highway Traffic Analysis, Maintenance, and Highway Bridges.

D—Research Equipment

The purpose of this section of Engineering Research is to give in concise form notes regarding the equipment of laboratories for mutual information and for the purpose of informing the profession of the equipment in various laboratories.

Hydraulics D1-22. Hydraulic Laboratories in the United States. A Directory of Hydraulic Laboratories in the United States has been compiled under the direction of the Hydraulic Research Committee of the Engineering Foundation, the members of which are J. Waldo Smith, Chief Engineer, Board of Water Supply of the City of New York, and Silas H. Woodard, Consulting Engineer, New York. The book has eighty-four 7 by 10-in. pages and contains information concerning 49 laboratories in engineering colleges, industrial establishments and governmental bureaus. Only statements furnished by the person responsible for the laboratory have been used in each case. Indirectly, this information affords comparison of equipment in the various laboratories and suggests possibilities of greater usefulness in some instances. The information will be helpful to those contemplating the establishment of new laboratories, to persons desiring to have hydraulic tests or experiments performed, and to students choosing schools in which to pursue the study of hydraulic engineering.

Persons desiring copies of the Directory of Hydraulic Laboratories, or more information regarding Engineering Foundation, should address Alfred D. Flinn, Secretary, 29 West 39th Street, New York.

F—Bibliographies

The purpose of this section of Engineering Research is to inform the profession of bibliographies which have been prepared. In general this work is done at the expense of the Society. Extensive bibliographies require the approval of the Research Committee. All bibliographies are loaned for a period of one month only. Additional copies are available, however, for periods of two weeks to members of the A.S.M.E. These bibliographies are on file at the headquarters of the Society.

Sampling, Coal, Ore, Liquids, etc. F1-22. The Bureau of Mines in its usual thorough way has just completed a bibliography of the literature on sampling. This report was prepared by Messrs. W. J. Sharwood and M. Von Bernewitz and is known by Serial No. 2336; 85 mimeograph pages, 8 by $10^1/_2$ in.

So far as is known, there is no complete bibliography on sampling; this one, therefore, should be of value. In it are nearly eleven hundred references, some dating back 30 years, on sampling at mines, mills, smelters, power plants, pumping stations and refineries. For convenience there are included a few references to methods for sampling such materials as leather belting in mills, salt-impregnated soils, and mine waters. All the important technical journals, including some in foreign countries and engineering society publications, also mining and metallurgical textbooks, have been studied for anything concerning sampling, and while it is not claimed that every important reference has been listed, the bibliography is fairly complete.

The arrangement is alphabetical by authors' names, and the references are numbered serially in the order that they appear in the bibliography. Anonymous references are listed under the name of the journal in which they appear, and are numbered like the references bearing an author's name. Patents are grouped in their numerical order, without index numbers. The report is provided with a subject index. Address H. Foster Bain, Director, Department of the Interior, Bureau of Mines, Washington, D. C.

CORRESPONDENCE

Contributions to the Correspondence Department of Mechanical Engineering are solicited. Contributions particularly welcomed are discussions of papers published in this journal, brief articles of current interest to mechanical engineers, or suggestions from members of The American Society of Mechanical Engineers as to a better conduct of A.S.M.E. affairs.

The Surge-Tank Problem

To the Editor:

The writer has carefully read an article by Professor Durand appearing in the October, 1921, number of Mechanical Engineering, in which he recommends the construction of models in order to solve surge-tank problems experimentally.

Such problems are so easily, quickly and accurately solved by the process of arithmetic integration that the necessity or desirability of a comparatively expensive model is quite incomprehensible to the writer.

Table 1 shows an example of arithmetic integration as applied to Professor Durand's first illustrative problem. For convenience the value of n is taken as 2 and an instantaneous shutdown is assumed. It is only a little more work to plot a reference curve for friction variation with $n = 1.85$, but there is no practical reason for doing so. The successive computations are made for time intervals of 10 sec. Only three columns of figures are necessary for this work and no figures whatever are used other than those set down.

Table 1

Changing Values of V	Corresponding Values of Y	Δh_f
10.000	7.721	0.00
0.124	7.625	
9.876	15.346	1.30
0.226	7.450	
9.650	22.796	3.60

1.460	88.508	48.94
0.637	0.635	
0.823	89.143	49.66
0.636	0.144	
0.187	89.287	

The time consumed in making this entire computation should not exceed 35 min.

The process should be apparent upon casual inspection, but it may be described as follows: Column 1 denotes velocity in the conduit, column 2 departure of water level upward from its original position, and column 3 the change in the friction loss.

During the first ten seconds the rise in water level of 7.721 is determined by dividing the conduit velocity by the constant 1.295, which is one-tenth of the ratio of the surge-tank area to the conduit area. For non-cylindrical tanks this ratio is simply made variable with respect to Y and read from a previously prepared curve.

In ten seconds' time the velocity in the conduit will change 0.0161 × the retarding head or, say, 0.124 during the first time interval. Subtracting this from the original velocity we have a new velocity of 9.876; dividing this by 1.295 we have 7.625, which added to Y gives the new value of Y as 15.346.

The change in friction from the original velocity to the present one is 1.3 ft., which subtracted from 15.346 gives the new accelerating head; this multiplied again by 0.0161 gives a retardation of 0.226 in the next time interval. This process is continued until the conduit velocity becomes zero, at which time the water has risen 89.287 ft.

The arbitrary unbalancing at the beginning is an inseparable feature of arithmetic integration, and although it is likely to hurt the feelings of pure mathematicians, the error which is initiated is not cumulative but rather is it self-corrective during the subsequent successive computations.

The change in friction can be read directly on a slide rule by squaring the velocity, multiplying by 0.5 and reading backward from 50 ft. on the upper slide. The subtraction of the friction change from the rise in each case need not be carried beyond the second place, and can easily be done mentally and set directly on the slide rule to be multiplied by the constant 0.0161. This example, to be sure, is a simple one, but there is no case too complicated not to be susceptible of the same general treatment.

When demanded loads are considered it is necessary to carry a fourth column denoting draft velocity, and this draft velocity may be made to vary in any conceivable manner, for example, in such a way as to keep the power output constant. Such a study would be in no way more difficult than the one illustrated, but would simply require more time.

7

It will be noted that in using the foregoing method no trial-and-error work is required. The computations are always straightforward, however complicated the problem. If greater accuracy should be required, the time interval could be cut in two, using 5 sec. instead of 10 and doubling the work, but it is hardly likely that the figure 89.287 differs from the true result by as much as three-quarters of one per cent.

The writer has had exceptional opportunities during the past twenty years to observe actual results as compared with such computations as are here presented, and he feels competent to make the unqualified statement that the construction of models for the purpose of solving surge-tank problems is a waste of time and money and cannot possibly lead to results as accurate as those which are easily computed. In fact, once the variation in friction is assumed known, the behavior of the model itself can be readily ascertained by numerical calculation, even for periodic load changes, and with greater accuracy than that with which it can possibly be observed experimentally.

The writer wishes to take particular exception to Professor Durand's fifth enumerated advantage of the model method, and to state the fact that periodic fluctuations of any sort are so assuredly within practical reach of numerical methods that he has found no difficulty in training inexperienced men to do such work. When the differential principle is used, periodic load changes never cause any serious trouble and therefore need no study.

A practically accurate formula for cases similar to the one here illustrated is as follows:

$$N^2 = \frac{6}{3K^2 - \left(2K + \frac{1}{K^2}\right)}$$

where $N^2 = 2gc^2v_2^2F/AL$ and K is the ratio of the total upward surge to the original friction loss, or $K = Y_1/CV_2^2$.

Where the differential principle is used in designing the surge tanks, it is usually unnecessary to resort to the expedient of arithmetic integration.

The direct use of such formulas as are published in the writer's article (Trans. Am.Soc.C.E., 1915) is quite sufficient to work out

accurately an ordinary design. The use of expensive models for the purpose of such solutions would be even more uncalled for, if possible, than in the case of the simple tank studies; furthermore it is difficult for the writer to find any excuse for omitting the differential principle when its use, without exception, produces a cheaper surge tank which will fulfill the same conditions.

For example, in the present instance a differential surge tank only 25 ft. in diameter would cause the water level to rise about the same amount as this 36-ft. simple tank, and it would behave better for the usual requirements of demanded load.

There are so many short cuts available to those who are familiar with the use of the slide rule to assist in arithmetic integration that it is impossible to point them out except in each special case, but they readily occur to most people as practice instructs them. The writer has never found a case too difficult to solve by simple commonsense processes which are available to the mind of any one familiar with Newton's laws of motion. Casting ahead or trial-and-error methods are almost never required. If great refinement is desired the time of a quarter-cycle should be divided into thirty or more parts, but twenty is usually sufficient for practical purposes, as here illustrated.

The interested student may try shorter time intervals. By plotting the final results of several such computations it is easy to find by extrapolation the practical limit where further subdivision of the time gains nothing in accuracy, and this point might well be found in the present case when thirty subdivisions were reached.

By plotting a reference curve between N and K (not N^2) from the formula given, all cases of non-spilling shutdown can be immediately solved with almost no effort, and the results are entirely trustworthy. The derivation of this equation, however, is too long to be set forth in this discussion.

Correction of an Error

The writer wishes to take this opportunity to correct an error of which he was guilty in a paper on the surge tank published in the 1908 A.S.M.E. Transactions.

This error was discovered some six or seven years ago, but inasmuch as no one ever called attention to it, he let it go uncorrected with the thought that where there was not shown a sufficient interest even to discover the mistake, it was probably doing no harm.

Recently, however, it has come to his attention that this old paper, although badly out of date, is still made use of by some engineers, and he therefore believes it worth while to point out what is probably its worst fault.

Reference is therefore made to page 850 of the volume in question, where there appears a formula for the critical size of a simple tank as follows:

$$R = \frac{Khg}{L}$$

As a matter of fact, K is not constant except for cases where C accidentally has the same value, or in other words, K varies with C and is equal to $2C$.

In this form it is known as the Thoma formula and the writer has also derived it independently. It will be observed that the critical value of R is independent of L because C varies directly with L.

New York, N. Y. R. D. Johnson.

Railway and Tramway Wheel Design

To the Editor:

Engineering has, of necessity, been largely a matter of development based on trial-and-error methods, and it has therefore happened that certain details of design or construction have become fashionable (the word is used advisedly) and an engineer must be something of a hero to suggest a departure from what are called standardized methods. Thus in railway practice the idea of keeping the rail joints opposite one another outlived its just life by many years, for as with the use of railway metals of large section and with improved fishplates resilience at the joint was almost eliminated; moreover the use of bogies on fast-traveling trains eliminated the jump that used to be so much feared as the wheels passed over the joints.

In a similar manner coning of the wheel treads was resorted to in some sort of belief that a compensating effect was produced when a pair of wheels, rigidly connected to an axle, passed round a curve; there seems to be a further underlying idea that in some way the coning assists in keeping the vehicle centralized on the track.

Even a cursory investigation of the circumstances of modern rolling stock on a heavy steel railway would reveal the necessity of a reconsideration of the relationship of the wheel and track, yet no one seems to have been bold enough to tackle the problem and obtain the best design of wheel.

The writer does not suggest that there may not be other factors to consider, but would merely point out the enormous loss and disadvantages that arise from the conical form of wheel tread at present in use; these may be summarized as follows:

1 *Loss of Power Due to the Compelling of a Conical Surface to Roll in a Straight Line.* If in an ordinary railway wheel the mean bearing surface of the rail on the flange gives a difference of circumference of 0.86394 in. and this difference has to be accounted for by an acceleration above the normal speed of revolution of the outer bearing line, or an equal retardation of the inner bearing line, of the tread; normally and presumably the difference should be divided, but in any case the skidding of the wheel metal is such as to require the application of 8910.8 ft-lbs. of work per ton per mile, over and above the ordinary effort of traction; and is moreover the circumstance that increases so enormously the starting effort required in rolling stock.

2 *The Wear and Tear Due to the Same Conditions.* The profile of the ordinary rail is such as to give initially a line bearing but it is not very long (two or three months in the case of tramways), before the rails are ground down to the tread profile and thence onward the grinding effort is equivalent to that calculated in (1), moreover in the street tramways the ordinary grind of metal on metal is enhanced by the interposition of street grit, foreign matter between the wheel and rail.

3 *The Elimination of Noise.* The writer was interested in a length of relaid tramway track and was surprised at the absence of noise so long as the wheel ran on the rails with narrow bearings, which was due to the tread of the wheel being straight and the rail top curved; but on reflection it is evident that the grind of steel on steel must necessarily create much of the usual noise associated with tramways and railways.

4 *Corrugation of Rails.* It must be quite obvious that in (comparatively light) resilient tramway rolling stock the chatter due to the slipping of one part of the wheel tread must cause a jump resulting in corrugations, but there must also be a certain synchronism developed due to some local peculiar feature of the track.

It was recently argued that once the rail became worn to the conical profile of the wheel tread, the principles enunciated above would not hold and that the New South Wales Railway Department canted the rails 1 in 20 to compensate for the coning, but geometrically it can be demonstrated that as long as the wheel tread is formed conical nothing will eliminate the disastrous factors enumerated; the best proof however, is to draw a wheel diagram with two treads, the inner one of the larger diameter and the outer one of the smaller diameter, and apply this to a rail stepped with a difference of the two radii, to allow each tread to bear; obviously one or other of the treads must grind.

The fillet of the ordinary wheel design is also a serious loss of power, as what applies to the cone applies equally and to a further extent (proportional to the radii of the similar lines of the fillet curve) to any part of the fillet bearing downward on the rail.

Sydney, N. S. W. F. Ernest Stowe.[1]

To the Editor:

The question raised by Mr. F. E. Stowe on the proper contour of the wheel tread whether initially coned or flat and train resistance loss resulting therein, is a matter worthy of further discussion.

Let us first consider the theoretical loss of energy resulting when perfectly coned wheels are displaced laterally a distance y from their central position and compelled to rotate in a longitudinal direction. If $1/n$ is the taper of the coned wheel and r the mean radius of the

---

[1] Civil and Consulting Engineer; M.I.E. (Aus.); Mem. Am.Soc.M.E.

wheels, then for the radii of the outer and inner wheel tread we have—

$$r_1 = r + \frac{y}{n} \text{ and } r_2 = r - \frac{y}{n}$$

If w = angular velocity of the wheels and v = velocity of translation of the axle, then $v = wr$ and the relative velocity or slippage velocity between tread and rail is—

and $wr_1 - v$ = backward slippage of tread for outer wheel (ft. per sec.)
$v - wr_2$ = forward slippage of tread for inner wheel (ft. per sec.)

Therefore if u is the coefficient of friction and N the normal wheel load, the friction forces at the base of treads are approximately equal to uN (lb.) and act forward on the outer wheel and backward on the inner wheel tread. The loss due to slippage is—

FIG. 1.

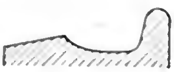

FIG. 2.

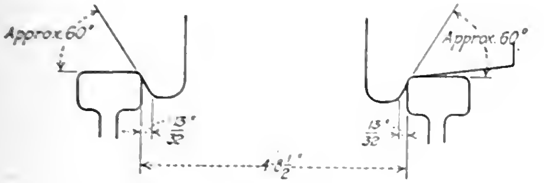

FIG. 3.

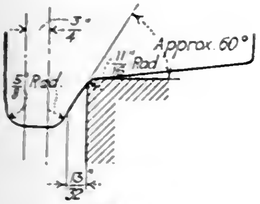

FIG. 4

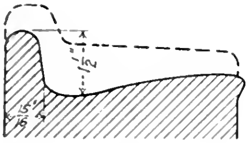

FIG. 5.

$$A_s = uN\left\{(wr_1 - v) + (v - wr_2)\right\} = \frac{2uNwy}{n} \text{ (ft-lb. per sec.)}$$

$$\therefore A_s = \frac{2uNvy}{rn} \text{ (ft-lb. per sec.)}$$

While the maximum possible train resistance per ton, with coefficient of friction $^1/_5$ is—

$$P_s = \frac{400y}{rn} \text{ (lb. per ton), approximately.}$$

The preceding results are based on estimating the relative work of slippage. For a better conception of the reactions involved in this slippage, the following analysis is of interest. Though the frictional forces for the outer and inner wheels at tread base are approximately equal and opposite, they cannot be the same due to the different radii of the treads, and it is due to their resultant differential effect which causes the drawbar resistance required for a given axle. If the wheel is moving with uniform motion, we have no angular acceleration and therefore, if F = total friction at base of outer tread and F' = total friction force at base of inner tread, we have,

$$Fr_1 = F'r_2 \text{ and } F' = \frac{r_1}{r_2}F \text{ (lb.)}$$

The axle resistance exerted at the journal bearings due this cause is—

$$P_s = F' - F = F\left(\frac{r_1 - r_2}{r_2}\right) \text{ (lb.)}$$

and the power loss is—

$$A_s = F\left(\frac{r_1 - r_2}{r_2}\right) v \text{ (ft-lb. per sec.)}$$

As a check, based on the relative work of friction, using the exact friction forces, we likewise have, as before,

$$A_s = F(wr_1 - v) + F'(v - wr_2) = F\left(\frac{r_1 - r_2}{r_2}\right) v \text{ (ft-lb. per sec.)}$$

Obviously these expressions reduce approximately to the values given above.

Fig. 1 shows the tread contour of the M. C. B. standard. The taper at the tread is 1 : 20 and if we assume a total flange play of $^3/_4$ in., $y = 0.375$ in. Hence the maximum train resistance per ton due to cone slippage of a new wheel is—

$$F_s = \frac{400 \times 0.375}{r \times 20} = \frac{7.5}{r} \text{ (lb. per ton)}$$

With an ordinary 36-in. car wheel this amounts to—

F_s = 0.4166 lb. per ton, or to 0.4166 × 5280 = 2200 ft-lb. per ton-mile.

Figure 2 shows the ultimate wear of a tread. From this it is evident that the contour of the tread soon changes from a conical surface to a flat bearing surface. The coning of wheels probably resulted in the early development with the idea of causing the axle to run radially around a given curve. Since the radius of curvature R for a given coning is $(G/2) \times (rn/y)$, where G is the track gage, it is evident that there can be only one curvature for a given theoretical coning. Thus the practical value of coning amounts to allowing a wearing depth for the new wheel, and this alone would seem to justify the continuing of this practice. The losses due to coning with a new wheel are at best relatively small; the maximum possible train resistance for full lateral displacement of the axle not exceeding $^1/_2$ lb. per ton. The average loss, since the mean of the lateral displacements is likely much less, would not probably exceed one-third of this value or $^1/_6$ lb. per ton. Roughly the total train resistance at slow speeds is 5 lb. per ton, therefore the slippage due to the coning of a new wheel is only from 3 to 4 per cent of the total friction and much less at higher speeds. Even assuming a very high coefficient of friction, the slippage due to coning could not account for more than 10 per cent of the total starting resistance.

It is of interest to point out other losses due to the contour of the wheel tread. At high speeds the flange is brought intermittently in contact with the rails first on one side and then on the other and the lateral reaction exerted at the flange is a function of several variables, including the elastic lateral resilience of the rail. Let the mean lateral be Y. With a small obliquity of the wheel, the flange contact takes place at the tread of the wheel. Let r' be the radius of the arc of contact of wheel flange and rail and ϕ the angle to any differential area of contact along the radius r' with respect to the horizontal. Then,

$$P = \int_0^{\pi/2} \frac{upr'd\phi \cos\phi \; r' \; (1 - \sin\phi)}{r}$$

where $p = Y/r$ and u = coefficient of friction. Since the projected bearing pressure in the direction of Y must always equal the actual bearing pressure, therefore

$$P = \frac{uYr'}{r}\int_0^{\pi/2} \cos\phi \; (1 - \sin\phi) \; d\phi = \frac{uYr'}{2r}$$

The reduction of the radius of the fillet tends to increase the depth of flange contact r', and in the wear the mean flange friction increases. Other considerations are a sufficient flange fillet to reduce high local stresses due to large lateral flange reactions. The mean value of the lateral reaction Y on tangent track is very indefinite, but it increases very rapidly with the speed.

Another cause of slippage loss is due to a slight obliquity of the axle when held in the boxes of the frame. Then the peripheral velocity of the wheel makes a small angle θ with the rail tangent. The friction force resulting from this cause in the longitudinal direction is evidently,

$$uW \tan\theta = uW\theta \text{ approx. (lb.)}$$

whereas the work done is—

$$uWv \tan\theta = uW\theta v \text{ (ft-lb. per sec.)}$$

where W is the axle rail load. With poor alignment of axles, this loss may reach appreciable values.

Contour of Wheel Flange and Tread in Practice. Figs. 3 and 4 show the essential contour of a new wheel and Fig. 5 the final wearing limit. We see, therefore, that the tread taper is quite justified in giving additional wearing depth and preventing the wheel after wear from having an excessive reversed taper. The mean life of the tread is actually on a flat surface. With a new wheel for the friction loss to be appreciable with a given coning, we must have a definite lateral displacement. This, however, is prevented, since the throat fillet is brought in contact with the rail and a large lateral reaction is exerted which results in centralizing the axle. With a new wheel and worn rail or with a slight spread of the rails a small lateral displacement is possible, but in the previous discussion the losses shown even in this case are relatively small. Hence the taper is justified in giving a good contour for the tread for average wear.

The dimensions of the flange and the flange fillet are based on wear and strength and proper contour to prevent derailment. For wear and strength a large fillet is desirable, whereas on the other hand too large a fillet will make the slope at the point of tangency to the flange top circle too small. The slope in practice is about 60 deg. and this corresponds to a fillet of radius $^{11}/_{16}$ in. and top flange circle of radius $^{5}/_{8}$ in. in an ordinary car wheel. Such a contour wears to a straight flange with a minimum thickness at root of flange equal to $^{15}/_{16}$ in. and total depth of $1^{1}/_{2}$ in. The value of the lateral flange reaction Y in terms of the normal wheel load N is given by the expression—

$$Y = N\left[\frac{\tan\phi - u}{1 - u\tan\phi}\right] \text{ (lb.)}$$

where ϕ is the slope angle. To show the importance of the slope angle and the coefficient u, the ratios of N/Y are given below:

u	$N/Y = 45°$	$N/Y = 60°$
0.0	1.000	0.577
0.1	1.221	0.718
0.2	1.500	0.874
0.3	1.860	1.058

Thus with an excessive fillet resulting in a low slope, say, 45 deg. the axle load must be roughly 2 × 1.86 = 3.72 times the lateral reaction required to prevent derailment, whereas with a standard wheel with a smaller fillet the axle load required is 2 × 1.058 = 2.116 (min.) times the required lateral reaction. With a smaller fillet the life of the wheel is shortened. It is well to maintain axle loads from 2.5 to 3.0 times the maximum guiding reaction.

In conclusion, it would seem that our standard practice for wheel contour is very much justified from theoretical aspects as well.

Philadelphia, Pa. R. Eksergian.

Second Revision of A.S.M.E. Boiler Code, 1922

A HEARING is held by the Boiler Code Committee at least once in four years, at which all interested parties may be heard, in order that such revisions may be made as are found to be desirable, as the state of the art advances. The year 1922 becomes the period of the second revision, the first revised edition of the Boiler Code having been issued in 1918. The Boiler Code Committee plans to hold a Public Hearing in connection with the next Annual Meeting of the Society in December, 1922, to which the membership of the Society and everyone interested in the steam-boiler industry will be invited and where they may present their views.

In the course of the Boiler Code Committee's work during the past four years, many suggestions have been received for revisions of the Power Boiler Section of the Code, as a result of the interpretations issued and also of the formulation of the Locomotive Boiler and Miniature Boiler Codes. In order that due consideration might be accorded to these recommendations, the Committee began in the early part of 1921 to devote an extra day at each of its monthly meetings to the consideration of the proposed revisions. As a result of this many of the recommendations have been accepted and revisions of the paragraphs formulated.

The revisions which have met the approval of the Boiler Code Committee are here published. It is the request of the Committee that these revisions be fully and freely discussed so that it may be possible for anyone to suggest changes before the rules are brought to final form and presented to the Council for approval. Discussions should be mailed to C. W. Obert, Secretary to the Boiler Code Committee, 29 West 39th St., New York, N. Y., in order that they may be presented to the Boiler Code Committee for consideration.

The revisions here published are limited to the paragraphs appearing in the 1918 Edition of the A.S.M.E. Boiler Code, and the paragraph numbers refer to the paragraphs of similar number in that edition. For the convenience of the reader in studying the revisions, all added matter appears in small capitals and all deleted matter in smaller type.

Par. 194 Revised:

194 *Domes.* THE REQUIREMENTS OF PARS. 187 AND 188 SHALL APPLY TO RIVETED LONGITUDINAL JOINTS OF DOMES EXCEPT THAT FOR DOMES 24 IN. AND LESS IN DIAMETER FOR PRESSURES EXCEEDING 100 LB., THE LONGITUDINAL JOINTS MAY BE LAPRIVETED IF THE FACTOR OF SAFETY IS NOT LESS THAN 8. [The longitudinal joint of a dome 24 in. or over in diameter shall be of butt and double-strap construction, irrespective of pressure. When the maximum allowable working pressure exceeds 100 lb. per sq. in., the flange of a dome 24 in. or over in diameter shall be double-riveted to the boiler shell.]

THE FLANGE OF A DOME 24 IN. OR OVER IN DIAMETER SHALL BE DOUBLE-RIVETED TO THE BOILER SHELL. WHERE THE FLANGE OF THE DOME IS USED FOR REINFORCING OR ATTACHING IT TO THE SHELL, THE DIAMETER OF THE DOME SHALL NOT EXCEED ONE-HALF THE DIAMETER OF THE SHELL OR BARREL OF THE BOILER. [The longitudinal joint of a dome less than 24 in. in diameter may be of the lap type, and its flange may be single-riveted to the boiler shell provided the maximum allowable working pressure on such a dome is computed with a factor of safety of not less than 8.]

The dome may be located on the barrel or over the fire-box on traction, portable or stationary boilers of the locomotive type. [Up to and including 48 in. barrel diameter. For larger barrel diameters, the dome shall be placed on the barrel.]

Flanges of domes shall be formed with a corner radius, measured on the inside, of at least twice the thickness of the plate for plates 1 in. thick or less, and at least three times the thickness of the plates for plates over 1 in. in thickness.

Par. 244 Revised:

244 The thickness of a corrugated or ribbed furnace shall be ascertained by actual measurement BY THE FURNACE MANUFACTURER BY GAGING THE THICKNESS OF THE CORRUGATED PORTIONS. IF A HOLE IS DRILLED THROUGH THE SHEET TO DETERMINE THE THICKNESS IT SHALL BE $^{3}/_{8}$ IN. WHEN THE FURNACE IS INSTALLED THE HOLE SHALL BE LOCATED BENEATH THE BOTTOM OF THE GRATE AND CLOSED BY A PLUG. The furnace shall be drilled for a $^{1}/_{4}$-in. pipe tap and fitted with a screw plug that can be removed for the purpose of measurement. For the Brown and Purves furnaces, the holes shall be in the center of the second flat; for the Morison, Fox and other similar types, in the center of the top corrugation, at least as far in as the fourth corrugation from the end of the furnace.

Par. 251 Revised:

251 After drilling or reaming rivet holes the plates and butt straps OF LONGITUDINAL JOINTS shall be separated, the burrs and chips removed, the plates and butt straps reassembled metal to metal with barrel pins fitting the holes, and with tack bolts.

Par. 265 Change Center Heading Above This Paragraph to:

WASHOUT [holes] OPENINGS

Par. 287 Revised:

287 When the valve body is marked [with the letters A.S.M.E. Std.] as required by Par. 273, this shall be a guarantee by the manu-

---

Note: Matter deleted, in smaller type; matter added, in small capitals.

facturer that the valve conforms to the details of construction herein specified.

Par. 294 Revised:

294 Each boiler shall have three or more gage cocks, located within the range of the visible length of the water glass, except when such boiler has two water glasses with independent connections to the boiler and located on the same horizontal line and not less than 2 ft. apart. LOCOMOTIVE-TYPE BOILERS NOT OVER 36 IN. IN DIAMETER NEED HAVE BUT TWO GAGE COCKS.

Par. 303 Revised:

303 When two or more boilers HAVING MANHOLE OPENINGS are connected to a common steam main, two stop valves, with an ample free-blow drain between them, shall be placed in the steam connection between each boiler and the steam main. The discharge of this drain valve must be visible to the operator while manipulating the valve. The stop valves shall consist preferably of one automatic non-return valve (set next the boiler) and a second valve of the outside-screw and yoke type; or, two valves of the outside screw and yoke type may be used.

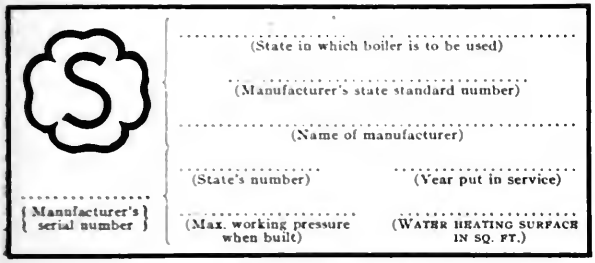

Fig. 24 Form of Stamping

Par. 315 Revised:

315 In a horizontal [return] tubular EXTERNALLY FIRED FIRE-TUBE boiler the feedwater shall discharge ABOVE THE CENTER ROW OF TUBES at about three-fifths the length from the front head (except a horizontal [return] tubular boiler equipped with an auxiliary feed-water heating and circulating device), above the central rows of tubes OR FLUES, when the diameter of the boiler exceeds 36 in. The feed pipe shall be carried through the FRONT head or shell [near the front end] in the manner specified for a surface blow-off in Par. 307, and be securely fastened inside the shell above the tubes.

In THESE AND other types of boilers where both internal and external pipes making a continuous passage are employed, the boiler bushing or its equivalent shall be used.

In Fig. 22 is illustrated a typical form of flange for use on boiler shells for passing through piping such as feed, surface, blow-off connections, etc., and which permits of the pipes being screwed in solid from both sides in addition to the reinforcing of the opening in the shell.

Par. 318 Revised:

A BOILER HAVING MORE THAN 500 SQ. FT. OF WATER-HEATING SURFACE SHALL HAVE AT LEAST TWO MEANS OF FEEDING, ONE OF WHICH SHALL BE A PUMP, INSPIRATOR OR INJECTOR. WHERE A SOURCE OF FEED IS AVAILABLE AT A SUFFICIENT PRESSURE TO FEED THE BOILER AGAINST A PRESSURE 6 PER CENT HIGHER THAN THAT AT WHICH THE SAFETY VALVE IS SET TO BLOW, THIS MAY BE CONSIDERED ONE OF THE MEANS. [When a pump, inspirator or injector is required to supply feedwater to a boiler plant of over 50 h.p., more than one such appliance shall be provided.]

Par. 332 Change Tabulation at End of Paragraph and Form of Stamping as Follows:

1 Manufacturer's serial number
2 State in which boiler is to be used
3 Manufacturer's state standard number
4 Name of manufacturer
5 State's number
6 Year put in service
7 Maximum working pressure when built
8 WATER HEATING SURFACE IN SQ. FT.

Items 1, 2, 3, 4, 7 AND 8 are to be stamped at the shop where built. Items 5 and 6 are to be stamped by the proper authority at point of installation.

PAINT PROTECTION FOR WOOD

(*Continued from page 520*)

that rubs off the layer of rust and exposes the nail to continuous corrosion. The working also abrades the wood and leaves the familiar large, rust-stained hole around an attenuated nail. The same conditions apply to the bolts and other steel fastenings in farm machinery, wagons, motor-truck bodies, and a long list of other articles. It is of vast importance in wood construction, therefore, that we have paints to protect the wood from absorbing moisture. Ordinary paint does not effectively do this except when a large number of coats is applied, and so far as the writer has been able to find out, there has been little or no attempt to produce a paint that will do it.

In the realm of house painting there seems to be a great possibility for economies, either by the use of cheaper paints which will give the necessary protection, or by the use of paints which will last longer. The writer is not familiar enough with this subject to warrant any comments other than to refer to Dr. A. H. Sabin's letter to the *Engineering News-Record* of August 18, 1921, in which he states that even the Pennsylvania Railroad is not always able to protect itself in the matter of paints, and he asks what chance the ordinary citizen has to check up on the paint he should use to protect the house that very possibly represents his life's savings. Paint literature of a technical nature is of no assistance to the average man, and is quite inadequate to explain the why and wherefore of much present practice. Great differences of opinion and some vague reasoning appear. Many contentions seem to be based on a desire to use certain materials or formulas, rather than on comparative service data of a reliable sort. Such men as Dr. Sabin of the National Lead Co., and Dr. Holly of Acme White Lead and Color Works, made frank acknowledgment of the shortcomings of paint technology and totally disavow any detail information concerning the effect of paints on moisture-proofing the cell structure of woods of various kinds. The Engineering Foundation has approved the desirability of this research and has appointed a committee to report ways and means of furthering it. This is a most substantial endorsement. The Society of Automotive Engineers and the American Institute of Architects have also approved and will lend their support.

It would seem that an intimate knowledge of wood cell structure is essential to any investigation of this subject. The Forest Products Laboratory is by all odds our most authoritative source of information on woods and their structure. The Director and his staff have been interviewed and fully agree that this research would be productive of important results, some of which could be expected in the course of 8 to 12 months; also that it can be handled there if funds in a very modest amount, between $10,000 and $20,000 per year, were made available for, say, from five to ten years. The Bureau of Standards has a paint division and has funds to work on the paint end of the research. Doubtless a coöperative arrangement could be made between these two of the most capable and helpful arms of our governmental service. Doubtless, too, the technical heads in the paint and varnish trade would place at the disposal of the Bureau of Standards and the Forest Products Laboratory their great fund of knowledge of paints and oils. Many of these men are already working on this problem, as has been set forth above; but they are handicapped by a lack of intimate knowledge of the various kinds of woods, and they are very much limited both in the time they can give and in the range of materials which they can test.

There is a crying need for such information, and inside of a year after the work is started a considerable amount of usable data should be forthcoming. The difference between the insignificant cost of the research and its value to the country at large is so vast that the writer believes it is only necessary to call attention to the matter in order to institute a widespread demand for action.

Standardization

The subject of standardizaton is now receiving much attention in all lines of industry and in all countries. Needless to say, such a universal question has many sides, and many varying and differing opinions are held as to the nature and extent of proper standardization. A very unusual and striking address on this subject was given recently by Mr. Albert W. Whitney, Chairman of the American Engineering Standards Committee before the National Construction Conference at Chicago. After pointing out the misconception that standardization will tend towards a world reduced to sameness, he continues:

> The difficulty will disappear if we realize three things about standardization: first that it does not belong with the vanguard, it comes along in the rear just ahead of the commissary department; second it is not exclusive, it does not attempt to pick out the one best, it picks out instead, many that are good; and third its judgments are not final but tentative and ever open to revision.
>
> In the march of progress the way is led by the visionaries, those who get the first gleam of the idea, the prophets, the artists, and the inventors; their heads are in the clouds but their feet are not always on the ground and so they have to be followed by minor prophets and minor artists and minor inventors who can capture the idea and tame it; then comes an army of critics and exploiters and executives, and at last the idea is put to work. But it doesn't work smoothly; the prophets and minor prophets and even the executives, who ought to know better, have left the ground in confusion. The good ideas are lost among a litter of impossible ideas, half-baked ideas, and ideas in every stage of futility. Somebody must come along and clear up, save what is good and throw the rest into the discard. This is the humble job of the standardizer.

This outline of the work of the standardizer will not be accepted universally. For one thing, it is not the duty of standardization to throw anything into the discard. Any given standard, to achieve its object, must meet the conditions of service in the majority of cases as well as, or better, than any other construction or practice would meet them. Yet after this is accomplished, exceptional conditions arise which no standard will meet properly. Every published standard might properly be prefaced with the remark, "Exceptional cases require special consideration." Thus many of the practices and constructions which are not suitable for general use, fill their own peculiar niche. On the other hand, the promulgation of logical standards will develop practice along unified lines, thus eliminating by an evolutionary process many slightly dissimilar ones.

Also, standardization deals with more concrete things than ideas. A large number of similar practices or constructions must be in general use before a need or demand for standardization exists.

Mr. Whitney goes on to describe the effects of standardization upon the processes of production and distribution.

> When deep thinkers and all their class find themselves free of the confusion created by the very fertility and multiplicity of their own ideas, they find that they can turn over the whole subject to a still more minor caste, those who look after routine. For instead of designing a truss or a belt or a generator or a fire-escape, the engineer has now only to specify a certain standard type or certain standard features that have already been worked out and the detail can then be left to subordinates.
>
> Now the prime importance of this upon progress is partly the acceleration and economy and convenience and efficiency that has therefore been produced, but to an equal degree it is due to the fact that the attention and energy of those who are on the frontier of knowledge has been set free for still further forays into the unknown.

Many machine designers object to the use of standard parts and constructions because they claim it robs them of initiative and originality. As a matter of fact, standardization in this field can never cover more than the relatively unimportant details. The use of standards, therefore, instead of hindering them, will free them from this minor detail and give them much more time and effort for creative work.

> With the thought well established then that standardization, if properly applied, not only does not interfere with the initiative and spiritual freedom upon which art and progress must depend, but is the very soil upon which they grow, may I now direct your attention to the wonderful things that this soil can produce.
>
> The result of throwing processes into the field of routine that have heretofore required explicit mental effort not only sets free this mental effort for other purposes, but makes possible mass-production; and indeed mass-production is impossible without standardization. In the opinion of Mr. Hoover and other students of industry, greater mass-production is necessary under our present post-war conditions if we are to maintain our standard of living and if we are to compete successfully with European industry. The relation between standardization and economy and efficiency in production is too plain to require further consideration.
>
> We may definitely make up our minds that we are beyond the era of the craftsman as respects the basic elements of our individual life. The era of machinery, if its peculiar genius is to be developed, leads us to standardization and mass-production. We still need the craftsman, but his place has been moved on into the field of finer values. It is the underlying basic elements of industry that I am discussing; in this field standardization, simplification, and mass-production must be developed to the greatest possible extent.

Exception may be taken to the statement that we are beyond the era of the craftsman. This may be due to the particular meaning that Mr. Whitney attached to this term. To my mind, the term "craftsman" has a peculiar significance. It implies not merely manual skill but also pride and interest in the work of the hands. It is true that in the productive departments of plants engaged in mass-production specialists rather than general mechanics are needed. Nevertheless there is great need of craftsmen among these specialists. No labor is so elementary that the spirit of craftsmanship is not needed for the best results.

> We are inclined to feel that the benefits of standardization apply mainly in the field of production. This is not so. They are quite as important both in the field of selling and of buying.
>
> The carrying in stock of the wide variety of sizes and grades that have grown up in a given field under the influence of the blind forces of demand, however casual, and competition, however misguided, has not only tied up an immense amount of capital but has taxed storage facilities and slowed up delivery. It is on record that an agricultural-implement house has recently been unable to make delivery of three carloads of wagons in spite of the fact that it had 12,000 wagons in stock. It is not too much to say that in most lines of business the variety that is found in stocks could be cut down to one-tenth of what it now is and serve perfectly well all reasonable demands. But it is the buyer quite as much as the producer and distributor that profit by standardization. The ordinary buyer is not an expert and he is therefore very largely at the mercy of the seller. He is not able to form an independent judgment of the quality and value of the goods that are for sale and he must therefore either buy in the dark or he must follow the advice of the seller. But if goods are standardized and marked so that they can be identified, it is possible for the buyer to familiarize himself with these standard lines, particularly if the unnecessary variety has been eliminated. He thus becomes an intelligent buyer; his purchases have greater utility and his discrimination reacts favorably upon the distributor and producer.
>
> And now having given you a very sketchy picture of the possibilities of standardization, I will tell you something about the agencies that are engaged in bringing it about.
>
> Unquestionably the most significant and promising event in the recent development of the standardization movement has been the entrance into the field of the Department of Commerce through the Division of Simplified Practice, newly organized by Secretary Hoover and in charge of Mr. W. A. Durgin, recently of the Commonwealth Edison Company of Chicago.

> The other outstanding factors in the situation are doubtless the Bureau of Standards, which for years has done such fine fundamental work, the U. S. Chamber of Commerce, Division of Fabricated Production, which has been active in arousing interest among trade organizations; and the American Engineering Standards Committee; although there are a multitude of other bodies which are taking an important interest in the movement.
>
> When a standard is approved by the American Engineering Standards Committee, it becomes known as an American Standard or as a Tentative American Standard and through no mandatory process, but because of the standing and representative character of the American Engineering Standards Committee, such standards become to a considerable extent adopted by industry and the Government. The American Engineering Standards Committee has approved nineteen standards and has sixty two other projects under way.

No standard is ever widely adopted because of the standing or representative character of the body which promulgates it. In the final analysis, a standard is adopted or rejected on its own intrinsic merits. The character of the body which issues them has much to do with their early trial, but their final acceptance depends entirely upon their worth.

Earle Buckingham.

Southern Appalachian Water Power Conference Establishes Permanent Organization

At a meeting held in Asheville, N. C., June 20 to 22, 1922, a permanent Southern Appalachian Water Power Conference was established to study the water-power resources of the Southern Appalachian region and their relation to industrial growth and navigation. Joseph Hyde Pratt, director of the North Carolina State Geological Survey was elected as the first president. The other officers are Lincoln Green, vice-president of the Southern Railway, vice-president; J. A. Switzer, secretary; and Professor Thorndyke Saville of the University of North Carolina, assistant secretary and treasurer. All the states south of the Ohio and Potomac rivers and east of the Mississippi are to be gathered into this Conference.

O. C. Merrill, secretary of the Federal Power Commission, presided over the Conference Sessions at which the speakers stressed the importance of basic information about stream flow, rainfall, etc., in order to hasten the development of water power with its resulting effect on the future of industry and transportation.

Charles E. Waddell of Asheville, N. C., in a communication to Secretary Rice of the A.S.M.E., emphasized the remarkable interest shown by the body of public-utility executives and engineers who gathered to discuss the subject of Southern Appalachian Water-Power Resources.

American Construction Council Organizes

Under the initial chairmanship of Secretary of Commerce Herbert Hoover, the American Construction Council was formally organized in Washington, D. C., on June 19, 1922. More than 200 men, representing 54 associations interested in the construction industry, attended the meeting.

The purpose of the Council is to place the construction industry on a high plane of integrity and efficiency and to correlate the efforts toward betterment through a conference association, representative of the whole industry and dedicated to the improvement of the service which the construction industry renders. It has included in its organization all the elements of industry, each with voting power. There are eleven groups: architects, engineers, general contractors, sub-contractors, construction labor, manufacturers, dealers, financial, bond and insurance interests, public utility construction departments, construction departments of federal, state and municipal governments, and building exchanges. Each group has four representatives on the executive board.

In his address at the opening session Chairman Hoover said that he believed the Council would help to stabilize the industry and eliminate undue speculation. He characterized the movement as one of the most important steps taken in the history of the industry. Walter Gordon Merritt, speaking on Determining the Proper Relations between the Several Elements of the Construction Industry, said that the Council must function so that constant coöperation between employer and employee must replace the "periodic armistices" which are now the history of their relations. He declared that the trouble with the industry now is due not to lack of organization but to organization with selfish motives. The Council must replace selfishness by a sense of responsibility to the public.

The second day of the meeting was taken up with discussion of what the Council might do to further the aims of the several groups. Committees were appointed on: code of ethics, seasonal unemployment, apprenticeship, building codes, transportation rates, publicity, simplification, standardization and waste elimination, and methods to be pursued in gathering statistics.

In discussing the finances of the organization, it was freely expressed that the Council would not be living up to its opportunities if in three years its annual budget was less than $250,000. No conclusion on the method of financing, other than by dues, was reached.

Upon the adjournment of the meeting the executive board went into session and elected Franklin D. Roosevelt, formerly Assistant Secretary of the Navy, president, and John B. Larner, president of the Washington Loan & Trust Co. and vice-president of the American Bankers' Association, treasurer.

Calvert Townley, Past-President of the American Institute of Electrical Engineers, spoke at the opening session, representing the engineering profession. The executive board members of the engineers' group are: C. T. Main, Boston; B. J. Arnold, Chicago; Peter Junkersfeld, New York; and C. F. Loweth, Chicago.

Engineering Council Takes Up Forest Conservation

It is self-evident that the preservation of forests is vital to future hydroelectric development as well as to the timber supply, soil conservation and flood retardation. These are all of importance to our civilization and of extreme interest to engineers. The American Engineering Council has a committee which will investigate conditions and take suitable action looking toward proper state and national legislation for forest preservation. This committee consists of Charles H. MacDowell of Chicago, chairman, S. H. McCrory of the Departmant of Agriculture, Washington, D. C., W. H. Hoyt of Duluth, Minn., and J. C. Ralston of Spokane, Wash.

The committee is investigating forestry conditions in all the states and has already received reports of the existing situation together with recommendations of the state forestry for measures of relief in what is described as "a critical period" in the development of a national policy of reforestation. Many of these recommendations center on fire prevention, development of nurseries, roadside tree planting, the supplying of proper stock for state and private reforestation, encouraging private reforestation through elimination of excessive taxes, new planting on public lands not suitable for tillage, whether federal or state owned, support of certain forestry bills now in Congress, and the encouragement of reforestation by coöperation between federal and state authorities.

France Awards Dr. A. E. Kennelly Cross of Legion of Honor

For distinguished services rendered as exchange professor in engineering to the French Republic, the Cross of the Legion of Honor has recently been awarded to Dr. A. E. Kennelly, professor of electrical engineering at Harvard University and the Massachusetts Institute of Technology. This honor may be conferred for meritorious service to the French Republic in military or civil life.

Dr. Kennelly was the first exchange professor sent to France from America under the scheme of regular annual exchange of professors in engineering and applied science, inaugurated last fall between the French University Administration and seven American institutions. The French representative in America, Professor J. Cavalier, rector of the University of Toulouse, and an authority on metallurgical chemistry, has recently returned to France after a year spent at the seven coöperating institutions, Columbia, Cornell, Harvard, Johns Hopkins, Massachusetts Institute of Technology, Pennsylvania and Yale.

The award of the Cross of the Legion of Honor to Dr. Kennelly is an indication of the success of the scheme for an exchange professorship in engineering. The undertaking will undoubtedly increase the mutual understanding between French and American engineers, and have a broadening effect on the profession.

NEWS OF OTHER SOCIETIES

American Society for Testing Materials

Thirty-five standing committees of the American Society for Testing Materials, all of which had been at work during the year revising present specifications and formulating new ones, presented reports at the twenty-fifth annual meeting of the Society held in Atlantic City June 26–30. Study of materials and test methods, for the first time in the history of the Society, took preference over specification work. The most important single item of the program so far as this new phase of activity is concerned was two sessions in which impact testing of materials and fatigue phenomena were discussed. The papers and discussions brought out the fact that there is not available as much definite information on impact testing as is desirable, and the Society plans to remedy this deficiency by making a thorough study of the subject in the future.

Sessions were held on Non-ferrous Metals and Corrosion, Steel, and Wrought, Gray and Malleable Iron. At the latter session revised specifications for foundry pig iron and for chilled cast iron were suggested by Committee A-3 of which Richard Moldenke, a member of the A.S.M.E., is chairman.

The newly elected President, G. K. Burgess, in his address said that the executive committee is considering ways and means of further circulating the Proceedings of the Society in foreign countries so that the American standards may become more generally known. An indication of the extent to which the standards are used in this country is shown by the fact that last year $18,000 worth of the Society's literature was sold.

The annual golf tournament was won by F. G. Breyer and the tennis tournament by R. W. Seabury. Officers elected in addition to the President, Mr. Burgess, are W. H. Walker, Vice-president, and W. K. Hatt, J. R. Onderdonk, D. M. Buck, and W. M. Corse, new members of the Executive Committee.

American Railway Association

The third annual meeting of the American Railway Association was held in Atlantic City June 14–21. The Mechanical Division held its sessions during the first three days. Reports were presented on the cost of labor and materials, arbitration, tank cars, loading rules, train lighting and equipment, car construction, couplers and draft gears, brake-shoe and break-beam equipment, train-brake and signal equipment, and car wheels.

The exhibition this year was one of the largest ever attempted by the Railway Supply Manufacturers' Association. In addition to machine tools and shop equipment, practically all kinds of railway equipment were exhibited, from complete locomotives and cars to the small devices used in the construction of railway rolling stock. There were in all about 350 exhibitors and 100,000 square feet devoted to exhibit space.

The attendance was large and representative of the membership of the division, which comprises the former Master Car Builders and Master Mechanics Associations. Headquarters were at the Marlborough-Blenheim Hotel, where the technical sessions were held.

American Foundrymen's Association

The twenty-sixth annual convention and exhibition of the American Foundrymen's Association, held in Rochester, N. Y., June 5 to 9, marked an epoch in the history of the Association in that it presented the first specially planned international session. Representatives of the foundry associations of Great Britain, France and Belgium took part in the session, which was a signal success. The feature among the technical papers at this meeting was the exchange paper from a member of the British Foundrymen entitled American Versus British Cast Iron, by F. J. Cook, Rudge-Littley, Ltd., Birmingham, Eng., Past-President of the Institute of British Foundrymen.

Two sessions were held on steel-foundry subjects and eleven papers and reports were presented. Interesting sessions were held on gray-iron topics, malleable iron and molding sand, industrial relations, and four sessions on non-ferrous matters were held as joint meetings with the Institute of Metals Division of the American Institute of Mining and Metallurgical Engineers which was holding a concurrent meeting.

The attendance and registration at both the technical sessions and exhibition were large, having been exceeded on only two previous occasions. The exhibition, although not the largest, was one of the most representative ever held. There were 173 exhibitors and the compact arrangement and the impression of unity were favorable factors. The exhibition was held in Exposition Park, not far from the buildings in which the technical sessions were held.

Officers elected for next year include C. R. Messinger, President; G. H. Clamer, Vice-president; and C. B. Connelley, Fred Erb, L. W. Olson and A. B. Root, Jr., Directors.

Society of Automotive Engineers

The semi-annual meeting of the Society of Automotive Engineers was held at White Sulphur Springs, West Va., June 20 to 24. A feature of the meeting was the report from a sub-committee on methods of numbering cars and engines so that obliteration or change of the numbers would be impossible without easy detection. The committee had had samples made up to test several of the most promising suggestions, but admitted that it had been somewhat surprised by the ease with which all of them had been beaten by the Underwriter's Laboratories.

At the meeting of the Standards Committee, reports were presented from the following divisions: Agricultural Power Equipment, Axle and Wheel, Electrical Equipment, Engine, Iron and Steel, Lighting, Non-ferrous Metals, Parts and Fittings, Passenger-car Body, Screw Threads, Springs and Stationary Engines. Special sessions were devoted to research, passenger cars, fuels and engines, aeronautics and motor buses. Mechanical problems were considered in papers by G. E. A. Hallett on Methods of Developing Aircraft Engines; by P. M. Held on Overhead Camshaft Passenger-Car Engines; and by H. M. Crane on A New System of Spring Suspension for Automotive Vehicles.

Considerable interest was aroused by a message from Secretary of Commerce Hoover offering the aid of his Division of Simplified Practice to the S. A. E. in securing the adoption of their standards. The message was presented by R. M. Hudson, of the Division. The report of the research director of the Society, Dr. H. C. Dickinson, was another of the interesting features of the meeting.

American Institute of Electrical Engineers

The thirty-eighth annual convention of the American Institute of Electrical Engineers was held at Niagara Falls June 26–30. The opportunity to visit and inspect the vast industrial developments which are operated by the power of Niagara Falls proved a lure to electrical engineers, and the attendance recorded, 950, was far in excess of expectations.

The address of welcome was delivered by A. Munro Grier, president of the Canadian Niagara Power Co., at the opening general session. A. P. M. Fleming addressed the Convention, representing the Institute of Electrical Engineers of Great Britain and the British National Committee of the International Electrotechnical Commission and the British Electrical Standards Association.

More than thirty technical papers, dealing with many phases of electrical engineering, were presented at the sessions, and discussion of these papers proved a valuable part of the Convention. Tuesday afternoon was devoted to a series of papers on the Queenton hydroelectric plant. Wednesday afternoon, set aside for a visit to the plant which contains the largest hydroelectric units ever built, was one of the high spots of the week. On Thursday morning a group of eight papers relating to cable insulation were presented, and Thursday evening was given over to a symposium on engineering education.

The officers of the Institute for next year are: President, F. B. Jewett of New York; Vice-Presidents, G. Faccioli, of Pittsfield, Mass., Prof. W. I. Slichter, of Columbia University, R. F. Schuchardt, of Chicago, H. W. Eales, of St. Louis, and H. T. Plumb of Salt Lake City; Managers, H. M. Hobart, of Schenectady, N. Y., Ernest Lunn of Chicago and G. L. Knight of Brooklyn. George A. Hamilton of Elizabeth, N. J., was reëlected Treasurer and F. L. Hutchinson of New York, Secretary.

John Fritz Medal for 1922 Awarded Senator Marconi

Wireless Inventor Receives Signal Honor before Distinguished Audience

BEFORE the largest gathering ever assembled on a similar occasion, the John Fritz Medal was presented to Senator Guglielmo Marconi on Thursday evening, July 6, at the Engineering Societies Building in New York City. The presentation of this Medal for 1922 attracted the interest of press and public in this and other countries, and the decision of the John Fritz Medal Board of Award in singling out the great Italian as medallist for his invention of wireless telegraphy has met with popular approval. The occasion of the formal conferring of the Medal was convincing evidence of the significance and influence of engineering in international affairs.

Previous to the presentation ceremonies, Senator Marconi was the guest of the Board of Award at a dinner at the Engineers' Club. Arrangements for the meeting were made by Prof. Comfort A. Adams of Harvard University, and Charles F. Rand of New York, chairman and secretary, respectively, of the John Fritz Medal Board of Award. Professor Adams presided at the meeting and read messages from other medallists, distinguished engineers and public men of America and Europe. The speakers included James R. Sheffield, prominent New York lawyer and president of the Union League Club; Michael I. Pupin, professor of electromechanics at Columbia University and famous for his inventions in the wireless art; and Elihu Thomson, former medallist, who presented the Medal to Marconi.

Underwood and Underwood

SENATOR GUGLIELMO MARCONI

Accepting the Medal, Senator Marconi said:

"I am extremely grateful for the very kind and flattering remarks which have been made in regard to myself and my work by the distinguished gentlemen who have been good enough to speak here tonight. It is indeed a great distinction and encouragement to further efforts, being received as I am, I may say, invariably received in this great country, and to meet here amongst my friends those who represent the best intellect in science and applied science as exemplified in the persons composing the great national engineering societies of America.

"I have long realized that in America more than anywhere else the most cordial and generous encouragement is given to any honest endeavor to apply science to useful and practical purposes.

"I consider myself fortunate that much of my early work in radio has been carried out in this country, for I cannot help feeling that you realize that wireless communication has become useful and often necessary on sea and on land, besides tending to increase and simplify the facilities for closer communications between distant peoples on this earth, thus contributing, I hope, to make goodwill take the place of the unrest and mutual suspicion which unfortunately seems at present to be a dominating feeling amongst the nations.

"It is a great honor for me to be admitted, through your award, to the ranks of the eminent men upon whom the John Fritz Medal has been bestowed. I beg to express my very high appreciation of this honor, and to offer my most grateful thanks for the distinction thus conferred upon me."

Senator Marconi is the nineteenth recipient of the John Fritz Medal. The award was established in 1902 as a memorial to the great engineer and metallurgist whose name it bears, and is presented for notable achievement in applied science. The Medal Fund was contributed by friends of Mr. Fritz and its administration was assigned to the Four National Engineering Societies.

The first award of the Medal was made to John Fritz on his eightieth birthday in 1902. Since that time eighteen awards have been made to men of the very highest distinction in the engineering profession. They include: Lord Kelvin, George Westinghouse, Alexander Graham Bell, Thomas A. Edison, Charles T. Porter, Alfred Noble, Sir William Henry White, Robert W. Hunt, John Edison Sweet, James Douglas, Elihu Thomson, Henry M. Howe, J. Waldo Smith, George W. Goethals, Orville Wright, Sir Robert A. Hadfield, Charles Prosper Eugene Schneider, and Guglielmo Marconi.

Four of the former medallists were present at the ceremonies in honor of Marconi. They were Dr. Elihu Thomson, prolific inventor in the field of applied electricity, Dr. J. Waldo Smith, who solved the problem of supplying New York City with water, Gen. George W. Goethals, builder of the Panama Canal, and Dr. Orville Wright, who with his brother Wilbur developed the first successful aeroplane. Attention was called to the presence of these four distinguished guests by the Chairman, and they were loudly acclaimed by the audience.

Professor Adams read messages of regret from Vice-president Coolidge, Herbert Hoover, Thomas Edison, Guido Sabetta, Charge d'Affairs of Italy at Washington, Sir Robert Hadfield of London, and Eugene Schneider of Paris.

The speakers of the evening dwelt upon different aspects of Marconi's life work and its meaning to human society. Mr. Sheffield pictured the personal side of the inventor, outlining his early life, his struggles and his ultimate triumph. He declared, "What Galileo was to his age, what Newton was to the law of gravitation, what Morse was to the telegraph, Bell to the telephone and Westinghouse to the airbrake, Marconi has been and is to the development of the wireless. His name will ever be linked to this most elusive, most fascinating and most marvelous of all modern achievements—the science and the art of miraculous radio."

Professor Pupin said: "No poet or philosopher of today would be sufficiently daring to predict with any degree of accuracy the future expansion of this new science. Preparations are now being made to transmit articulate speech from the new world to the old; these preparations will end in a great success, I am sure, and after this success who will deny the possibility that before many years have passed the word spoken in this great engineering hall will be heard in every other engineering hall on the face of the globe?....This will be the growth from the seed which Senator Marconi dropped into a fertile field."

The meeting was regarded among engineers as a forward step in developing and promoting closer relations between Italy and America and advancing the general idea of a world engineering union.

Proposed Standard for Malleable-Iron Screwed Fittings

Historical

The Sectional Committee on the Standardization of Pipe Flanges and Fittings, which is sponsored by the Committee of Manufacturers on Standardization of Fittings and Valves, the Heating & Piping Contractors National Association, and The American Society of Mechanical Engineers, has completed the preliminary report reproduced below and desires now to submit it to Industry for general review and criticism.

At the beginning of the committee's investigation a good deal of effort was directed toward the setting up of a standard for 150-lb.

Proposed American Standard for Crosses, Tees, 90 Deg. and 45 Deg. Ells, Both Straight and Reducing, for 150-Lb. Working-Steam Pressure

---

Note: To illustrate the use of the Table for Reducing Fittings, let it be assumed that the Center to End Dimensions of a 6 x 4 x 5 Tee are required: Then for X dimension read opposite 6 and under 5 = 4.63 in. Then for Y dimension read opposite 4 and under 5 = 4.41 in. For Z* dimension read opposite 5 and under 6 = 5.03 in. Dimension Z is determined by using largest run opening.

malleable screwed fittings, in which each dimension should bear a definite relation either to the outside diameter of pipe, or to the American Standard Pipe thread elements, or to a combination of both. This scheme as contemplated would produce a fitting shorter and lighter than a majority of those in common use. Considerable progress was made along this line of effort, and no doubt a satisfactory line of fittings might have been arrived at in this way. Fittings so designed, however, would not "line up," some sizes being considerably shorter than customarily made. It was, therefore, feared that they would be criticised by consumers and would be objectionable from the manufacturers' standpoint in that they could only be tapped with the American thread.

For these reasons it became the unanimous opinion of the members of the committee that the standard fitting should not depart greatly from those in common use and should be of such dimensions that the castings could be tapped with either American threads or with other commonly used pipe threads (British) without change in cores and without interference of tools.

Descriptive

The above schedule of dimensions fulfills these requirements. Fittings made to this schedule will have dimensions equal to or greater than the minimum dimensions contained in the British Engineering Standards Association Report C. A. (M) 1637, and will have the following outstanding features:

1 Can be tapped either British or American Standard pipe thread both as to gage and length of threads in all sizes except the $2^{1}/_{2}$-in. which can be tapped American Standard pipe thread only, British $2^{1}/_{2}$-in. pipe being 3-in. O. D. whereas American pipe is only 2.875 in. O. D.

2 In casting the cores can be made from the same coreboxes for both malleable- and cast-iron fittings thus reducing the investment necessary for the production of a line of malleable- and cast-iron fittings.

3 Will not depart materially from dimensions of fittings already produced by some manufacturers which have demonstrated excellent appearance and serviceability

4 Can be varied in thickness of wall and size of bead, from the minimum which is considered the lightest advisable for the service for which they are recommended to any weight found necessary by any manufacturer, as the exigencies of his foundry and shop practice may require and still conform to the standard.

Engineering and Industrial Standardization

Safety Code for Conveyors and Conveying Machinery under Way

An important step toward the solution of an accident problem has just been accomplished through the decision of the American Engineering Standards Committee that the development of a Safety Code for Conveyors and Conveying Machinery be undertaken.

The introduction of mechanical conveyors in many industries has eliminated a large proportion of the accidents resulting from the manual handling of materials, but it has at the same time introduced new hazards, many of which can be prevented by a more general agreement among both users and manufacturers of conveying equipment as to safe practices in the manufacture, installation, and operation of such equipment.

The American Society of Mechanical Engineers and the National Bureau of Casualty and Surety Underwriters have been appointed joint sponsors for this code. All interested national organizations will be asked to coöperate in the formulation of the code. This code, the American Engineering Standards Committee announces, will be intended as a guide for the safe operation and maintenance of conveyors and conveying machinery coming under the following main divisions: gravity, belt, chain, flight bucket, apron, screw and jigging conveyors, car hauls, aerial cableways, overhead trolley, and pneumatic tubes.

All shafting, pulleys, belts, link belts, chains, gears, sprockets, couplings, clutches, etc., used on and in connection with conveyors and conveying machinery will be covered in the Mechanical Power Transmission Code now in preparation.

Big Standardization Program Proposed for Electric Railway Field

A standardization program of considerable importance to the iron and steel, lumber, electrical, construction, chemical, railway and railway-supply industries is presented in the submission by the American Electric Railway Association of 13 standards for approval by the American Engineering Standards Committee.

The specifications submitted to the A.E.S.C. follow:

For Approval as American Standards

9-in. Girder Grooved Rail
7-in. Girder Grooved Rail
9-in. Girder Guard Rail
7-in. Girder Guard Rail
Joint Plates for 7-in. Girder Grooved and Girder Guard Rails
Joint Plates for 9-in. Girder Grooved and Girder Guard Rails
Specification for Galvanizing or Sheradizing on Iron and Steel

For Approval as Tentative American Standards

7-in. 80-lb. Plain Girder Rail
7-in. 91-lb. Plain Girder Rail

For Approval as Recommended American Practice

Specification for Materials for use in the Manufacture of Special Track Work
Specification for 600-Volt Direct-Current Overhead-Trolley Construction.

Four special committees will be appointed by the American Engineering Standards Committee to determine whether the A.E.R.A. specifications are the standards which should be adopted for universal use in the United States; the Committee's decision will, of course, be predicated on its finding as to the desirability of national standardization of the products enumerated. The principal organizations concerned will be asked to name representatives on these special committees.

One special committee will be asked to conduct the investigation with respect to the acceptability to the industry of the specification for 600-volt direct-current overhead-trolley construction; another committee will conduct the investigation concerning the specifications for wood poles and tubular poles; a separate committee will study the specifications for galvanizing or sherardizing on iron and steel; and a fourth committee will go into the subjects of the remaining nine related specifications. The findings of these committees will be reported to the American Engineering Standards Committee as soon as the investigations are completed.

Meanwhile, the American Engineering Standards Committee requests the technical press, industrial associations, and technical bodies interested in these specifications to send to its headquarters at 29 West 39th Street, New York City, any available information as to the extent to which these specifications are meeting the needs of the industries concerned.

In submitting these standards, J. W. Welsh, executive secretary of A.E.R.A. wrote to the American Engineering Standards Committee as follows: "The committees in which the various specifications were prepared have been composed of men chosen for known experience and ability, and include electric-railway operating and construction engineers, producers and consulting engineers."

Colors for Traffic Signals to be Standardized

The day is not far off when red, green and yellow, when used as traffic signals, will each have its distinctive meaning and this meaning will be uniform all over the country, according to the decisions reached at the first fully representative conference ever held on the subject in this country. When that day arrives the annual toll of deaths and serious injuries resulting from traffic

accidents will be reduced by the elimination of accidents caused by the confusion or misunderstanding of signals.

This conference on the standardization of colors for traffic signals was recently held in New York under the auspices of the American Engineering Standards Committee. There were present representatives of practically all of the big national engineering societies, safety associations, electric- and steam-railway interests, automobile dealers, manufacturers' and users' associations, police and traffic departments, insurance companies, and several departments of the federal government.

The conference agreed unanimously "that there should be national uniformity in the use of colors for signals" and that the detailed technical work involved in bringing about such uniformity should be carried out by a thoroughly representative sectional committee under the auspices and procedure of the American Engineering Standards Committee. Included in the scope of the work as defined were the following:

- The use of colored lights on all highway vehicles
- Their use on all signals along highways and at curbs, both permanent and temporary
- Their use for highway-crossing signals or steam and electric railways
- A coördinated relation of color, form, position and number of signals
- A coördinated relation to systems of flashing, moving or other similar lights
- Colors for non-luminous as distinguished from luminous signals
- Recommendations on the use of colors for emergency exit signals
- Methods of specifying or defining colors for signals purposes
- Any other closely related matters which, in the opinion of the sectional committee, form a part of the subject to be considered

Mr. A. H. Rudd, on behalf of the American Railway Association, presented a paper in which were summarized the general facts of the situation affecting the steam railroads, and suggested lines along which they would like to see standardization progress. While signal systems of different railroads differ in some respects, fundamentals are largely standardized. For the operation of trains these include: red for danger (stop); yellow for caution; and green for clear.

A paper by Mr. H. B. Flowers gave the experience of the American Electric Railway Association. The standard use for signals in electric-railroad practice is: red for stop; yellow for proceed with caution; and green for proceed at schedule speed. Blue, purple and white are also used in a restricted way, for conveying special information or for safe-guarding special conditions.

A suggestion that yellow light be used in place of red for the tail light of automobiles brought forth spirited discussion during which Mr. Alden L. McMurtry of the Department of Vehicles of Connecticut said: "It is very easy to place the entire responsibility for automobile accidents on the automobile driver while, as a matter of fact, the responsibility for conditions which exist rest not merely on the motorist, but also on the pedestrian and upon the steam and electric railways.

"Pedestrians often cause automobile accidents by ignoring traffic rules. Watchmen are not always at grade crossings when the signs say they should be there; and grade-crossing gates are, at times, down for considerable periods when trains are not going through. National uniformity in colors for traffic signals is extremely desirable, but if major changes are to be made, as for example, a change in the color of tail lights for automobiles, it would take at least two years to get such changes into operation because legislation would be required in most states."

On the motion of Dr. M. G. Lloyd of the U. S. Bureau of Standards, a resolution was adopted declaring it to be the sense of the conference that any sectional committee of the A.E.S.C. which takes up the standardization of colors for signals should endeavor to coördinate such standardization with existing standards for traffic purposes, such as those used in water and aerial navigation and on steam and electric railways.

The conference did not advocate the substitution of green for red as a danger signal, as was erroneously reported in certain of the daily papers through a misinterpretation of discussion at the conference. On the contrary, the ideas expressed at the conference were emphatically that red should be used to indicate danger and for no other purpose. In conformity therewith, it was suggested that green be substituted for red as the color for lights for emergency exits of public buildings as indicating paths that lead to safety.

No final technical decisions were reached at the conference, these being left to be worked out in detail by a thoroughly representative sectional committee.

C. Russ Richards Welcomed at Lehigh University

C. Russ Richards, Mem. Am.Soc.M.E., president-elect of Lehigh University, was given a "welcome dinner" by the alumni of that institution in the University Commons on Friday evening June 9. Dr. Richards was introduced to this new constituency by William C. Dickerman, Mem. Am.Soc.M.E., an alumni member of Lehigh's Board of Trustees. In a felicitous address Mr. Dickerman described the two-years' successful search for a man who could unite faculty, alumni, student body and trustees. Dr. Richards was given a great "hand" when he rose to respond. He modestly stated that he had not had time nor opportunity to formulate any hard-and-fast policy or plan. He intimated that any reorganization would grow up out of conferences and after a painstaking ascertainment of the existing situation.

Dr. Richards excited the sympathy of all present by referring to Seth Low's definition of a college president as one "who gives and receives pain." He then sketched out in frank fashion his own faith as to the essentials of a technical education, especially as to the importance of thoroughness and the personal touch between student and teacher. He said that he did not want an enrollment in Lehigh much above what it was, 1,000, but would rather have it an outstanding institution of its class in which a breadth of knowledge and an understanding of men would be given recognition alongside of the more technical studies. He protested against undue specialization at the expense of breadth of education and pleaded for a study of the problems of life and of men. He believed that engineers should stand between labor on the one hand and the employer on the other and that there is less importance in what we teach than in how we teach it. After expressing the hope that the library could be much enlarged and saying that he intended to stress research he closed with an eloquent appeal for educational experiments, neither radical nor revolutionary, in order to develop a system which would train for leadership.

Dr. Richards will be the sixth president of Lehigh University, Drs. Copper, Leavitt, Lamberton, Drown and Drinker preceding him. He is the second engineer in the line. Dr. Drown was a mining engineer, Dr. Leavitt a minister, Drs. Copper and Lamberton learned in belles lettres, while Dr. Drinker was a lawyer. Dr. Richards will finish out the present academic year as Dean of the School of Engineering at the University of Illinois, and take up his new duties in South Bethlehem on September 1.—M. L. C.

Dr. W. H. Maw Elected President, Institution of Civil Engineers

Dr. William Henry Maw, Past-President of the Institution of Mechanical Engineers, Past-President of the Royal Astronomical Society, Fellow of the Royal Geographical Society, and member of the A.S.M.E., has been elected President of the Institution of Civil Engineers of Great Britain.

Dr. Maw has been a joint editor of London *Engineering* since 1866, and it is largely due to his editorial policies through over half a century that this paper has received world wide recognition as a leader in the field of engineering journalism.

Dr. Maw received his early engineering training as a railroad engineer in the Works of the Great Eastern Railway. He served notably in the War, being a member of the Advisory Panel of the Munitions Inventions Department in the British Ministry of Munitions. He is the author of several books on engineering subjects, including railroad and marine engineering, and of astronomical papers. He was a member of the Royal Commission for the St. Louis Exposition in 1904. Dr. Maw is a veteran engineer. He was born in 1838, and has been a member of the A.S.M.E. since 1913.

LIBRARY NOTES AND BOOK REVIEWS

L'Azote. By Louis Hackspill. Masson et Cie; Gauthier Villars et Cie, Paris, 1922. (Encyclopédie Léauté.) Paper, 5×8 in., 271 pp., illus. 14 fr.

As a member of military commissions of chemical control in Germany, the author acquired an intimate knowledge of the nitrogen industry and had an opportunity to study thoroughly the commercial plants at first hand. His book deals with the different processes, giving the history of each and describing the reactions and apparatus used. The various processes are also compared critically from the economic point of view.

Building Contracts. By Edwin J. Evans. E. P. Dutton & Co., New York, 1922. (Directly useful technical series.) Cloth, 6×9 in., 304 pp. $5.

A book on business management for contractors, dealing with the various matters that chiefly affect the administration of a contractor's business, and giving suggestions as to the best means of mobilizing and organizing the available forces for the financial and constructional success of the work. Adapted to conditions and practices of the building trade in England, but may be suggestive in this country.

Coal. By Elwood S. Moore. John Wiley & Sons, Inc., New York, 1922. Cloth, 6×9 in., 462 pp., illus., maps, tables, $5.

Prepared to satisfy the demand for a convenient modern summary of the voluminous scattered literature on coal. Covers quite fully such topics as the properties, origin, uses and general distribution of coal, while discussing only in a more general way such subjects as mining machinery and the details of distribution and character of local deposits.

Dynamics of the Aeroplane. By René Devillers. Translated by W. J. Walker. New impression. Lond., E. & F. N. Spon., Ltd., London, 1922. Cloth, 6×9 in., 302 pp., 15s.

The author's investigation is concerned with the effects upon the equilibrium of an airplane of the movement of its center of gravity and that about its center of gravity; or in other words of the different paths of flight and of its stability. The theoretical considerations are considered and the mathematical formulas evolved, but the principal aim has been to condense experimental results into simple technical form which the engineer can put to immediate use. All current formulas have been reduced to nomographic form, the book being, according to the translator, the first in English to adopt that method throughout.

Electric-Power Systems. By William T. Taylor. Sir Isaac Pitman & Sons, Ltd., London and New York, 1922. (Pitman's technical primer series.) Cloth, 4 × 6 in., 107 pp., $0.85.

This little book is an extremely brief introductory statement of the main technical facts and principles governing modern practice in the larger electric power systems. General circuit conditions are considered; the most important methods and problems in generation, transmission and distribution practice are explained; and special attention is paid to system operation, to the various "system factors" used, and to the importance of keeping reliable operating records.

Essai D'Optique sur la Gradation de la Lumiere. By Pierre Bouguer. Gauthier-Villars et Cie, Paris, 1921. (Les maitres de la pensée scientifique.) Paper, 5×7 in., 129 pp., 3fr.

This classic of the literature of optics is an account of Bouguer's study of certain important optical problems connected with the radiation of light and its absorption by various substances. It is the work which first set forth the basis of photometry, and led to the invention of the photometer by the author in 1748. The present edition reproduces the original text of 1729.

Industrial Fatigue and Efficiency. By H. M. Vernon. E. P. Dutton & Co., New York, 1921. Cloth, 6×9 in., 264 pp., tables, $5.

The author, who is an investigator for the Industrial Fatigue Research Board of Great Britain, presents a fairly complete account of our present knowledge concerning industrial fatigue and its influence on efficiency. The information adduced relates only to shop practice, as laboratory investigations have not, in the author's opinion, afforded much evidence of practical value.

Introduction to Electrodynamics. By Leigh Page. Ginn & Co. Boston and New York, 1922. Cloth, 6×8 in., 131 pp., $2.

The object of this book is to present a logical development of electromagnetic theory founded upon the principle of relativity. So far as the author is aware, the universal procedure has been to base the electrodynamic equations on the experiments of Coulomb, Ampère and Faraday, even books on the principle of relativity going no farther than to show that these equations are covariant for the Lorentz-Einstein transformation. As the dependence of electromagnetism on the relativity principle is more intimate than this covariance suggests, he believes it more logical to derive the electromagnetic equations directly from this principle. The book covers topics appropriate for a one-year graduate course in electrodynamics and electromagnetic theory of light. It should interest those who are looking for a logical rather than a historical account of the science.

General Economic Geology. By William Harvey Emmons. First edition. McGraw-Hill Book Co., Inc., New York, 1922. Cloth, 6×9 in., 516 pp., illus., $4.

This volume is an introduction to the study of mineral deposits, for use by students with a knowledge of the elements of general geology and mineralogy. It embraces the geology of mineral fuels, structural materials and other non-metals, and of the metals. The first chapter includes introductory matter, definitions and an outline of the classification of mineral deposits. It is followed by a treatment of coal, petroleum and the solid bitumens. Then follows a more detailed discussion of the classification and genesis of mineral deposits, which is succeeded by sections on non-metals and metals. Numerous footnotes call attention to the principal sources of information on each topic.

La Matiere et l'Energie selon la Theorie de la Relativite et la Theorie des Quanta. By Louis Rougier. New edition, revised and enlarged. Gauthier-Villars & Co., Paris, 1921. Paper, 7×10 in., 112 pp., 9.50 francs.

This book calls attention to the most paradoxical and least discussed consequence of the principle of relativity, that which attributes mass, weight and structure to energy. What we call matter thus becomes only a particular case of energy. The old duality of ponderable and imponderable makes way for that of the electro-magnetic field or *energy*, of which radiation and matter are simple modalities, and of the field of gravitation of *space* as defined by Einstein. Professor Rougier presents these theories in this work.

Metal Cutting Tools. By A. L. De Leeuw. First edition. McGraw-Hill Book Co., Inc., New York, 1922. Cloth, 6×9 in., 328 pp., illus., diagrams, $3.

The book is intended to bring before the reader the principles that must be applied in selecting, designing, maintaining and, especially, in using metal-cutting tools. It is intended for engineers, foremen, time-setters and mechanics. But slight use is made of mathematics, and mathematical knowledge is not essential for an understanding of most subjects considered.

Maschinenuntersuchungen und das Verhalten der Maschinen im Betriebe. By A. Gramberg. Second edition, revised and enlarged. J. Springer, Berlin, 1921. Cloth, 6×9 in., 681 pp., illus.

Volume two of the author's treatise on methods for testing machines, the first volume of which is devoted to measuring apparatus. This volume discusses methods of testing and the behavior of machines while running. The subjects treated include boiler tests, fuel tests, heat conductivity, steam turbines and reciprocating

engines, exhaust steam utilization, internal combustion engines, pumping machinery, blowers, air compressors and refrigerating machines. A section is devoted to regulation and governing. An introductory section discusses the economic and legal aspects of tests. The work is intended to assist in the selection of proper tests, to describe correct tests and to indicate how the results of costly tests can be fully analyzed.

Mechanical Stokers. By Joseph G. Worker and Thomas A. Peebles First edition. McGraw-Hill Book Co., Inc., New York, 1922. Cloth 6×9 in., 258 pp., illus., tables, diagrams, $3.

Although stokers are treated in books on boilers and power-plant equipment, there has been no work treating the stokers as a separate unit until the appearance of the present volume. It treats the phenomena of combustion in relation to stokers, describes mechanical stokers and modern practice in stoker installation and use, and discusses the selection of stokers for different fuels and differing conditions. The authors have endeavored to give reliable unbiased opinions and facts from field experience in design, installation and operation.

Modern Gas Tractor. By Victor W. Page. Fourth edition, revised and enlarged. The Norman W. Henley Publishing Co., New York, 1922. Cloth, 5×7 in., 590 pp., illus., diagrams, $3.

The object of the author has been to present the principles of design in a simple manner and to show how these principles have been followed in various types of construction, so that the advantages of the various methods may be intelligently analyzed by the average farmer and mechanic. The book is intended to assist in the selection of the best mechanism for individual requirements. Chapters on maintenance and repair are included.

Notes Economiques D'un Metallurgiste. By Camille Cavallier. Gauthier-Villars et Cie, Paris, 1921. Paper, 6×9 in., 153 pp., 3 fr. 50.

These brief economic discussions, by a French iron manufacturer, treat various present problems of French industry, particularly metallurgy. Such questions as the comparison between the foreign trade of France and Germany, the participation of manufacturers in national affairs and the relations of the heads of enterprises with capital and labor are treated, and the causes of and remedies for the present economic crisis are discussed in the light of long experience in industry.

Organic Chemistry. By Victor von Richter. Vol. II. Chemistry of the carbocyclic compounds. P. Blakiston's Son & Co., Philadelphia, 1922. Cloth, 6×9 in., 760 pp., $8.

After an interval of six years since the appearance of volume one, the second volume of this translation, dealing with the carbocyclic or closed carbon chain compounds, is now available. The translation follows the 11th German edition, prepared in 1912. The outstanding feature of this work is the large number of compounds listed, with outlines of the methods for preparing them and accounts of their important properties. No other book of its size gives such an exhaustive list. Because of this comprehensiveness, the book is most useful for reference, particularly when the large encyclopedias are not accessible.

Principles of Electrical Engineering. By William H. Timbie and Vannevar Bush. John Wiley & Sons, Inc., New York, 1922. Cloth, 5×8 in., 513 pp., illus., $4.

This textbook, written for students of college grade, with a knowledge of calculus and physics, aims to provide a substantial first course in the subject which will present rigorously, yet in understandable form, the basic principles underlying modern electrical engineering, to be followed by detailed courses in direct and alternating current machinery. Special features are the stressing of the subject of the magnetic circuit; the use of the electron theory as a basis for explanation; the inclusion of the subjects of thermionic omission, conduction through gases, electrolytic conduction and high-frequency phenomena; a novel approach to the subject of the behavior of dielectrics and numerous live problems.

Principles of Mechanical Refrigeration. By H. J. Macintire. First edition. McGraw-Hill Book Co., Inc., New York, 1922. Cloth, 6×8 in., 252 pp., illus., diagrams, $2.50.

Based on a "study course" of twenty articles published in *Power* during 1920. The book is intended to cover the entire field of refrigeration in an elementary manner, with little use of mathematics. Analogies to steam machinery and steam cycles are used to explain the action of refrigeration.

Steam Power Plant Auxiliaries and Accessories. Terrell Croft, editor. First edition. McGraw-Hill Book Co., Inc., New York, 1922. Cloth, 6×8 in., 447 pp., diagrams, illus., $3.

This book is intended to give data that will assist the power-plant engineer to select proper auxiliary equipment and install, operate and maintain it so that preventable losses will be kept as low as possible and power will be generated at the least cost. The subjects treated include pumps, boiler-feeding apparatus, feed-water heaters, economizers, condensers, cooling ponds and towers, steam piping, steam separators and steam traps. The treatment is simple, non-mathematical and descriptive.

Steel Foundry. By John Howe Hall. Second edition. McGraw-Hill Book Co., Inc., New York, 1922. Cloth, 6×9 in., 334 pp., illus., diagrams, tables, $4.

Mr. Hall's object has been to set forth the metallurgy of the steel foundry from the point of view of the engineer interested in prescribing the cheapest means of producing objects of sufficient excellence for the purposes for which they are intended. His book considers the classes of steel castings in demand today and their characteristics from a manufacturing point of view; the types of steel-making processes in use and the characteristics that govern the selection of one or another for making the sort of castings desired; and shop procedure in the light of its influence on quality and cost. The revision has introduced new data on electric-furnace practice, on molding sands, heat treatment and other phases of foundry practice.

Thermal Stresses in Chilled Iron Car Wheels. By G. K. Burgess and R. W. Woodward. Government Printing Office, Washington, 1922. (Technologic papers of the Bureau of Standards, No. 209. Paper, 7×10 in., 34 pp., plates, diagrams, $0.05.

Describes a method for testing car wheels under conditions nearly like those encountered in descending long grades, and gives the results obtained from a series of tests. Twenty-eight wheels of varying weight and design were tested, sixteen of which cracked in the plate. The tests suggest the possibility of improving the design of these wheels.

COMPOUNDING THE COMBUSTION ENGINE

(Continued from page 527)

he believes they will serve to mark a definite turning point in combustion-engine construction. Meanwhile he agrees with the discussion that it is to be regretted that he did not have the performance, say, the fuel consumption, of a larger than 7-in. cylinder to base reports on when the paper was written. Larger engines are, however, usually better than smaller engines and certainly much better than minute engines in this regard. The smallness of the 7-in. cylinder has been referred to several times, but let us examine the performance of this little engine. It has given 0.302 and 0.305 lb. of 16 to 22 Baumé fuel per indicated horsepower-hour in spite of the fact that it has all the imperfections of an experimental engine. This the author does not hesitate to submit as being a fairly good performance for this size of machine, being about the same as that recently reported on the *William Penn* engines with their ponderous $29^{1}/_{8}$-in. cylinders. Entirely unnecessary wire drawing exists at two points in this engine, which was found to rise to larger proportions than was expected and has been eliminated in later designs. Other than this, the mechanical losses in this engine are extremely low, as referred to in the paper.

To those who profess to see no virtue in compounding, it may be said that if the thermal units were being excessively absorbed by the chilled walls or are going astray in the many ways claimed by such critics, they most emphatically would never reach the indicator. This, the author feels, is a more complete answer to the various points raised than is sometimes realized.

THE ENGINEERING INDEX

(Registered United States, Great Britain and Canada.)

THE ENGINEERING INDEX presents each month, in conveniently classified form, items descriptive of the articles appearing in the current issues of the world's engineering and scientific press of particular interest to mechanical engineers. At the end of the year the monthly installments are combined along with items dealing with civil, electrical, mining and other branches of engineering, and published in book form, this annual volume having regularly appeared since 1906. In the preparation of the Index by the engineering staff of The American Society of Mechanical Engineers some 1200 technical publications received by the Engineering Societies Library (New York) are regularly reviewed, thus bringing the great resources of that library to the entire engineering profession.

Photoprint copies (white printing on a black background) of any of the articles listed in the Index may be obtained at a price of 25 cents a page. When ordering photoprints identify the article by quoting from the Index item: (1) Title of article; (2) Name of periodical in which it appeared; (3) Volume, number, and date of publication of periodical; (4) Page numbers. A remittance of 25 cents a page should accompany the order. Orders should be sent to the Engineering Societies Library, 29 West 39th Street, New York.

ACCIDENT PREVENTION

Mines. An Inventory of Results of Accident Prevention, C. A. Allen. Trans. Amer. Inst. Min. & Met. Engrs. issued with Min. & Metallurgy, May 1922, no. 1135 M, 9 pp., 8 figs. Facts and figures in effort to reduce fatalities in Utah.

ACETYLENE

Generating Plant. Acetylene Generator, Messer & Co. Type (Überflur-Azetylenentwickler, Bauart Messer & Co.). Zeit. für komprimierte u. flüssige Gase, vol. 22, no. 2, 1922, pp. 17–21, 3 figs. Detailed description. Freedom from risk, automatic charging of carbide, its complete gasification.

AERONAUTICAL INSTRUMENTS

Operation Recorders. Showing An Aviator How He Flies. Aviation, vol. 12, no. 23, June 5, 1922, pp. 658, 659, 2 figs. Three special instruments developed by N.A.C.A. for accurately recording aviator's operations and performance of aeroplane in flight. See also Aerial Age, vol. 15, no. 11, May 22, 1922, p. 249.

AERONAUTICS

Aerial Laws and Safety Survey. Aerial Laws and Survey of Safety in Flight Urged by Aeronautical Chamber of Commerce. Aerial Age Weekly, vol. 15, no. 11, May 22, 1922, pp. 246–247. Report of Aeronautical Chamber of Commerce points out meager capital, insufficient terminal facilities, popular doubt as to reliability, and need of aerial code, as hindrances to development.

AIR COMPRESSORS

Foundry. The Compressor for Foundry Purposes. Compressed Air Mag., vol. 27, no. 6, June 1922, pp. 159–161, 5 figs. Lubricating system, method of regulation, air receiver and aftercooler have much influence upon operation of pneumatic devices.

AIR FILTERS

Visco. A New Form of Air Filter. Engineer, vol. 133, no. 3456, Mar. 24, 1922, pp. 339–340, 2 figs. Describes Visco air filter, in which filtering medium consists of an innumerable mass of short rings cut from very thin coppered steel tubing, coated with film of mineral oil termed Viscinol. See also Elec. Rev., vol. 90, no. 2321, May 19, 1922, p. 717.

AIR PUMPS

"Delas" Air Extractor. Tests of a "Delas" Air Extractor. Elec. Ry. & Tramway Jl., vol. 46, no. 1130, May 12, 1922, pp. 205, 207–208, 3 figs. Results of test on Delas air extractor, manufactured by Société Condenseurs Delas, with regard to its use in reducing steam consumption.

AIRCRAFT

Commercial. More Business at Less Cost Marks Commercial Aircraft Growth. Automotive Industries, vol. 46, no. 22, June 1, 1922, pp. 1165–1173. Survey of operations in U. S. Practical utility definitely demonstrated. Expansion averages about 20 per cent.

Performance Testing. Performance Testing of Aircraft, T. M. Barlow. Aeronautical Jl., vol. 26, no. 137, May 1922, pp. 152–176, 21 figs. Outline of method carried out in England with special reference to routine at R.A.F. Aeroplane Experimental Establishment, Martlesham Heath.

Power Requirements of. Some Power Requirements of Aircraft, D. Roesch. Armour Engr., vol. 13, no. 4, May 1922, pp. 223–234, 7 figs. General discussion, with special reference to helicopter.

Radio Antennae. Radio Antennae of Aerial Vehicles (Sulle antenne radiotelegrafiche dei veicoli aerei), Algeri Marino. Elettrotecnica, vol. 9, no. 11, Apr. 15, 1922, pp. 242–247, 6 figs. Discusses differences from terrestrial antennae.

AIRPLANE ENGINES

Bavarian Motor Works 185-Hp. Performance of B.M.W. 185-Horsepower Airplane Engine, S. W. Sparrow. Nat. Advisory Committee for Aeronautics, Report no. 135, 1922, 10 pp., 22 figs. Deals with test made in altitude chamber of Bur. of Standards upon a Bavarian Motor Works engine, having six water-cooled cylinders with bore of 5.90 in., stroke of 7.09 in., and compression ratio of 6.7.

Bristol "Lucifer," 100 Hp. The 100 Hp. Bristol "Lucifer" Passes its Type-Tests. Flight, vol. 14, no. 19, May 11, 1922, pp. 267–268, 2 figs. Description of tests showing fine performance of this air-cooled engine.

Design. Aeronautical Engines, Their Evolution and Actual Tendencies (Les moteurs d'aviation, évolution, tendances actuelles), Martinot-Lagarde. Bul. de la Société d'Encouragement pour l'Industrie Nationale, vol. 134, no. 3, Mar. 1922, pp. 187–222, 23 figs. Commercial and military engines; characteristics of aeronautical engines, their mechanical construction, efficiency; engines for high altitudes; supercharging; etc.

Efficiency. Useful Work of High-Speed Explosion Engines (Het nuttig effect der moderne snelloopende explosiemotoren), I. Bauly. Ingenieur, vol. 37, no. 13, Apr. 1, 1922, pp. 244–257, 7 figs. Review of literature by engineer of Dutch Aeronautical Service, discussing useful mechanical work, useful thermic effect, fuels and combustion, heat balance of aero engines, etc.

Estimating Performance in Flight. Method for Estimating Power and Fuel Consumption of Normal Compression Aviation Engines in Flight at Various Altitudes. Air Service Information Circular, vol. 4, no. 317, Mar. 15, 1922, 6 pp. Object of report is to furnish standard method for estimating performance.

Starters, Buzzer. Fifty-Hour Endurance Flight Test of Auxiliary Starting Device (Buzzer Starter) for the Liberty Engine. Air Service Information Circular, vol. 4, no. 302, Feb. 15, 1922, 1 p., 1 fig. Results of test to determine durability of "buzzer" starter in actual flight service.

AIRPLANE PROPELLERS

Deformation During Flight. Determination of the Amount of Deformation of the Propeller Blades During Flight (Bestimmung der Deformationsgrösse von Schraubenblättern im Marsche), R. Katzmayr. Motorwagen, vol. 25, no. 12, Apr. 30, 1922, pp. 223–225, 4 figs. Discusses two methods, one by fixing an incandescent bulb at end of propeller blade, and other by using a source of light visible in proportion to number of revolutions.

AIRPLANES

Fuel Tanks, Safety. Safety Fuel Tanks for Aeroplanes. India-Rubber Jl., vol. 63, no. 18, May 6, 1922, pp. 17–19, 5 figs. Air Ministry prize of £1400, in official competition for petrol tanks used in aircraft won by I.R.G.P. Co. with an interesting rubber covered tank. Describes tests and the successful Silvertown tank. See also Aeroplane, vol. 22, no. 19, May 10, 1922, pp. 336 and 338.

Irwin "Meteorplane." The Irwin "Meteorplane." Aviation, vol. 12, no. 21, May 22, 1922, p. 599, 2 figs. Small single-seater tractor biplane designed to meet demand for small light-weight airplane of conventional design; 2-cylinder air-cooled engine; 15 hp. at 1900 r.p.m.

Static Test. Report of Static Test of Ski for an SE-5 Airplane. Air Service Information Circular, vol. 4, no. 322, Mar. 15, 1922, 1 p., 2 figs. Results of test conducted for purpose of determining structural strength of SE-5 ski. Description of ski.

Stress Analysis of JL-6. Study of Stress Analysis of the JL-6. Air Service Information Circular, vol. 4, no. 332, Mar. 15, 1922, 2 pp. Methods used in design of German airplane developed by Hugo Junker.

Tires and Wheels. Discussion of Airplane Tires and Wheels. Air Service Information Circular, vol. 4, no. 303, Feb. 15, 1922, 11 pp., 8 figs. Notes on wheel designs, rims, wheel lacing, hub attachment, tires, physical tests of wheels and of tires, designers' limitations, etc. Presents charts showing load deflection for airplane tires of standard sizes.

Vickers Commercial. The Vickers "Vulcan" Eight-Passenger Commercial Biplane. Flight, vol. 14, no. 18, May 4, 1922, pp. 253–254, 255–258, 22 figs. Description of plane nearing completion at Weibridge works, equipped with 360-hp. Rolls-Royce "Eagle VIII" engine.

Wing Spars. The Design of Wing Spar Sections, E. P. Warner. Aviation, vol. 12, no. 22, May 29, 1922, pp. 626–627, 2 figs. Develops formulas and gives curves.

AIRSHIPS

German. The German Airship (Das deutsche Luftschiff), Werner v. Langsdorff. Schiffbau, vol. 23, nos. 31 and 33, May 3 and 17, 1922, pp. 910–942 and 985–990, 10 figs. May 3: Detailed description of development and construction of Parseval type. May 17: Describes equipment in detail and gives list of Parseval ships from 1906–1916.

Semi-Rigid. Italian Semi-Rigid Airships (Il dirigible semirigido italiano), G. Arturo Crocco. Rivista Marittima, vol. 55, no. 3, Mar. 1922, pp. 901–927, 9 figs. Developments from France and Lebaudy types; horsepower and load; possibilities of aerial navigation.

ALLOYS

See ALUMINUM ALLOYS, COPPER ALLOYS, FERRONICKEL, MAGNESIUM ALLOYS, PHOSPHOR BRONZE.

ALUMINUM

Solders for. Investigation of Some Solders for Aluminum. Air Service Information Circular, vol. 3, no. 298, Feb. 15, 1922, 1 fig. Determination of effect of small additions of aluminum, copper, magnesium, on alloys of tin-zinc base used for aluminum soldering.

Uses. Aluminum and Its Utilization (Die Verwendungsgebiete des Aluminiums), J. Czohralski. Zeit. fur Metallkunde, vol. 14, no. 1, Jan. 1922, pp. 1–7, 8 figs. Chemical and mechanical properties of aluminum and aluminum alloys and selection of alloys for particular purposes.

ALUMINUM ALLOYS

Aluminum-Silicon. New Aluminum-Silicon Alloys, R. E. Search. Metal Industry (N. Y.), vol. 20, no. 5, May 1922, pp. 183–185. Description of "Aladar," "Aludar" and "Silumin" all alloys of aluminum and silicon, and their origin.

Properties. Properties of Aluminum Alloys. Am. Mach., vol. 56, no. 22, June 1, 1922, pp. 805–806. Why these alloys make good castings; saving in cost shown in relative weights; advantages of melting

AMMONIA

Pressure-Total Heat Diagram. The Pressure-Total Heat Diagram for Ammonia. H. J. Macintire and G. H. Bohn. Ice & Refrigeration, vol. 62, no. 5, May 1922, pp. 392–394, 2 figs. Simple graphical representation of properties of saturated and superheated ammonia, based upon Bur. of Standards and Goodenough-Mosher data, illustrating various refrigeration cycles, etc.

AMMONIA COMPRESSORS

Compound. Compound Ammonia Compression, G. A. Horne. A.S.R.E. Jl., vol. 8, no. 6, May 1922, pp. 455–487, 3 figs. Methods of intercooling. Cylinder ratios for compound ammonia compression. Horsepower curves.

Cylinder Design. Compressor Cylinder Design, J. H. H. Voss. Refrig. World, vol. 57, no. 5, May 1922, pp. 11–15, 11 figs. Importance of providing effective valve area in order to prevent waste of power through excess cylinder pressure. Table for calculating correct valve area.

Valves for High-Speed. Valves for High-Speed Ammonia Compressors, J. H. H. Voss. Power, vol. 55, no. 16, Apr. 18, 1922, pp. 619–621, 8 figs. Summarizes desirable points of construction that should be incorporated in design of every light plate valve if used on ammonia compressors.

ANEMOMETERS

Thermometric. The Thermometric Anemometer, J. S. G. Thomas. Lond., Edinburgh & Dublin Philosophical Mag., vol. 43, no. 256, Apr. 1922, pp. 688–698, 3 figs. Calibration curves of low-capacity anemometer of thermometric type for velocities of a few cm. per sec. and upward, and variations caused by heat losses due to conduction and radiation.

APPRENTICES, TRAINING OF

Systems. Trends in Management, William Leavitt Stoddard. Factory, vol. 28, no. 5, May 1922, pp. 528–529, 548 and 550, 2 figs. Deals with apprenticeship plan, and describes certain systems in the United States.

ARTILLERY

Cartridge Cases, Testing. Testing Artillery Cartridge Cases, J. Burns Read and S. Tour. Am. Inst. Min. & Met. Engrs. Trans., advance paper, no. 1151-N, Mar. 1922, 53 pp., 44 figs.; also (abstract) in Min. & Metallurgy, no. 184, Apr. 1922, pp. 33–35, 3 figs. Summary of metallurgical information and experience gained by Ordnance Dept. during war in manufacture of artillery cartridge cases. Describes tests to which artillery cartridge cases were put.

ASBESTOS

Fire Prevention. The Part Asbestos Plays in Fire Prevention, Maurice J. Hoover. Fire & Water Eng., vol. 71, no. 20, May 17, 1922, pp. 899–900, 905 and 920, 6 figs. Nature provides certain non-burnable materials which can be used for building purposes; advantages of asbestos for roof covering; importance of interior fireproofing.

ASH HANDLING

Plants. Pneumatic Ash Handling Plant (Pneumatische Entaschungsanlagen), Philippi. Archiv fur Warmewirtschaft, vol. 3, no. 4, Apr. 1922, pp. 63–66, 9 figs. Details of construction of small and large plants and advantages of pneumatic conveying.

Sluicing and Pumping. Pumping Ashes. Eng. & Indus. Management, vol. 7, no. 15, June 1, 1922, pp. 481–482, 1 fig. Sluicing process for removal of ashes.

ATOMS

Isotopy. Recent Results of the Investigation of the Atom (Neuere Ergebnisse der Atomforschung), Karl Przibram. Elektrotechnik u. Maschinenbau, vol. 40, no. 18, Apr. 30, 1922, pp. 205–210, 2 figs. Discusses question of isotopy of certain elements which, in spite of different radioactive behavior and different atomic weights, show exactly same chemical properties.

AUTOGENOUS WELDING

Safety Device. A New Safety Device for Autogenous Welding (Eine neue Rückschlagsicherung als Ersatz für Wasservorlagen in Schweissereibetrieben), Theo Kautny. Autogene Metallbearbeitung, vol. 15, no. 7, Apr. 1, 1922, pp. 93–96, 2 figs. Describes device for preventing oxygen from entering acetylene supply pipe, which might lead to explosion.

AUTOMOBILE ENGINES

Boring Machines for Crankcase. Boring and Running-In Machine for Motor-Omnibus Crankcases. Engineering, vol. 113, no. 2941, May 12, 1922, pp. 586–588, 11 figs. Description of recently invented tool by which through four simultaneous operations three crankcases can be finished per hour.

Cams and Poppet Valves. Experiments on Cams and Poppet Valves, G. E. Scholes. Automobile Engr., vol. 12, no. 163, May 1922, pp. 151–157, 16 figs. Introduces formulas and charts. Paper read before Inst. Automobile Engrs.

Crankshafts, Machining. Machining a Case Hardened Mack Crankshaft, Fred H. Colvin. Am. Mach., vol. 56, no. 16, Apr. 20, 1922, pp. 585–587, 9 figs. Hard and long-wearing surfaces secured by case hardening. Straightening, turning and grinding operations, balancing, final straightening and inspection.

Machining the Peerless Crankshaft, Fred H. Colvin. Am. Mach., vol. 56, no. 17, Apr. 27, 1922, pp. 621–623, 6 figs. Machining crankshaft for eight cylinder motor, double connecting rods require long crankpin bearings. Details of oiling and methods of drilling oil holes.

Cylinders, Casting. Cylinder Casting. Eng. Production, vol. 4, no. 86, May 25, 1922, pp. 493–496, 10 figs. Methods used in Midland Motor Cylinder Co., Ltd., near Birmingham.

Cylinders, Renewing. Renewing Cylinders, Paul Dumas. Motor Age, vol. 41, nos. 20 and 21, May 18 and 25, 1922, pp. 16–20 and 16–20, 17 figs. May 18: Equipment and tooling-up. May 25: Parts machining and fitting.

Ignition. Automobile Ignition, Chas. Baxter. Engineering, vol. 113, no. 2941, May 12, 1922, pp. 578–579, 10 figs. Investigation with view to bringing out relative methods of magneto and coil for battery systems.

Regrinding Parts. Regrind Automobile Engine Parts, F. B. Jacobs. Abrasive Industry, vol. 3, no. 4, Apr. 1922, pp. 118–121, 6 figs. Worn cylinders are reground and fitted with oversize pistons and rings; crankshaft regrinding must be performed accurately.

AUTOMOBILE FUELS

Alcohol. Alcohol Motor Fuel Research. Motor Transport, vol. 34, no. 898, May 15, 1922, pp. 600–601, 6 figs. Encouraging interim report issued by Empire Motor Fuels Committee of Imperial Motor Transport Council.

AUTOMOBILE INDUSTRY

Renault Works, France. The Works of the Société Anonyme Renault. Engineering, vol. 113, no. 2943, May 26, 1922, pp. 639–643, 11 figs. Description of 640,000-sq. yd. plant which manufacturers own iron and steel castings, rolls metal to their own dimensions; develops 15,000 b.hp.

AUTOMOBILES

American in Argentine. The American Automobile Holds Dominant Place in Argentine Republic. Automotive Industries, vol. 46, no. 19, May 11, 1922, pp. 1024–1025. American car will hold its position because of many requirements, giving service, and low price.

Axles, Rear. A Dual Reduction Rear Axle, Fred H. Colvin. Am. Mach., vol. 56, no. 18, May 4, 1922, pp. 663–665, 12 figs. Cutting-off, drilling, boring and milling methods on a forged axle. Fixtures which facilitate easy handling.

Brake Couplings. Are Cables Superior to Rods for Brake Couplings? M. W. Bourdon. Automotive Industries, vol. 46, no. 20, May 18, 1922, pp. 1059–1060, 8 figs. European makers claim cables stronger. Sunbeam, Minerva, Ansaldo, Lorraine-Dietrich, and La Licorine furnish some excellent examples of current practice.

Cubitt Car, British. British Cubitt Car Designed to Compete with American Products, M. W. Bourdon. Automotive Industries, vol. 46, no. 19, May 11, 1922, pp. 1006–1009, 8 figs. New British model designed for quantity production to compete with low-priced American cars in home market. Has 4-cylinder $3\frac{1}{8} \times 5\frac{1}{2}$-in. engine 4 speeds, worm drive and cantilever springs.

Design. Modern Tendencies in Automobile Construction (Zur Kritik der neuen Richtlinien im Automobilbau), R. Conrad. Motorwagen, vol. 25, nos. 4, 5 and 6, Feb. 10, 20 and 28, 1922, pp. 63–73, 83–87 and 105–115, 52 figs. Feb. 10: Hydraulic gears; gears in constant engagement with relay couplings; possiblities of standardization. Feb. 20: Construction of light pistons and cylinders for two- and four-stroke engines. Feb. 28: Describes some recent two-stroke engines; suction and compression; improvements in driving; adding new speeds for slow driving; etc.

Differential. With and Without the Differential, Louis Coatalen. Autocar, vol. 48, no. 1385, May 6, 1922, pp. 741–743. Reply to Granville E. Bradshaw's rejoinder. Evolution of touring car is based on racing practice; why solid axle is used on some racings cars; used on small cars because it permits better spring suspension.

Manufacture. Better Cars at Lower Price; A Production Achievement, J. E. Schipper. Automotive Industries, vol. 46, no. 22, June 1, 1922, pp. 1147–1149 and 1157. Marketing and production closely allied. Machine-tool development important. Careful shop planning major factor in ability to join quality with quantity production.

Short-Ashby Light Car. The Short-Ashby Light Car. Auto, vol. 27, no. 1115, May 18, 1922, pp. 405–408, 9 figs. Excellent example of friction-driven car, with some interesting mechanical features. Ruby 4-cylinder engine, 8 hp.

Sport. The Design of Sporting Cars, F. Gordon Crosby. Autocar, vol. 48, no. 1380 and 1381, Apr. 1 and 8, 1922, pp. 521–523 and 578–580, 12 figs. Apr. 1: Describes special type of body combining comfort with smart appearance. April 8: Difficulties in connection with convenient and aesthetic mounting of important accessories.

Starter Armature. Novel Starter Amature Eliminates Use of Soldered Commutator Joint. Automotive Industries, vol. 46, no. 21, May 25, 1922, p. 1108, 2 figs. Closed end of armature coil located at what is usually commutator end. Separate commutator dispensed with. Two armature bearings are placed closer together. Simplified construction greatly reduces production cost.

Surrey Light Car. The Surrey Light Car. Auto, vol. 27, no. 1116, May 25, 1922, pp. 425–427, 10 figs. Vehicle of sound design with good record of competitive achievement; Coventry-Simplex "O. E." type, 4-cylinder monobloc 10.5 hp. engine.

Suspension Design. The Design of Motor Car Suspensions, A. A. Remington. Automobile Engr., vol. 12, no. 163, May 1922, pp. 139–141, 2 figs. Consideration of factors involved and some conclusions.

Suspension Springs. European Makers Adopt Quarter Elliptic Springs for Light Cars, M. W. Bourdon. Automotive Industries, vol. 46, no. 22, June 1, 1922, pp. 1153–1157, 18 figs. Modifications in original application have been found necessary in practice. Standard and Wolseley offer good examples of "safety leaf." Carrow shows use of radius rod in construction.

AVIATION

Air Ports, Organization of. The Organization of Airports. Aviation, vol. 12, no. 23, June 5, 1922, pp. 660–662, 4 figs. Information division, air service issues revised specifications and rules for ground organization.

Gliders. See FLIGHT, Soaring.

Light, Use in. The Use of Light as an Aid to Aerial Navigation, L. F. Blandy. Illuminating Engr., vol. 15, no. 2, Feb. 1922, pp. 42–58 and (discussion) 58–63, 8 figs. Lights carried on aircraft, internal and external; aerodrome lighting; ground illumination; aerial light houses.

B

BATTERIES

E.M.F. at Low Temperatures. Electromotive Force of Cells at Low Temperatures, G. W. Vinal and F. W. Altrup. Sci. Papers of Bur. of Standards, no. 434, Apr. 17, 1922, pp. 627–634, 2 figs. Experiments of temperatures as low as —170 deg. cent. when high values of voltage were sometimes observed and polarity was often reversed.

BEAMS

Calculation. Expansion of the Clapeyron Equation (Erweiterung der Clapeyronschen Gleichung), Edgar Schmidt. Eisenbau, vol. 13, no. 4, Apr. 21, 1922, pp. 71–77, 7 figs. Assumes statically indeterminate main systems for derivation of this equation to simplify work of calculating beams with *n* supports.

Deflection. Some Problems in Deflection of Beams, Ewart S. Andrews. Concrete & Constructional Eng., vol. 17, no. 4, Apr. 1922, pp. 235–243, 4 figs. Gives derivation of formulas for deflection of beams for two cases not usually dealt with in textbooks.

BELTING

Leather. Power Transmission by Belting, P. F. O'Shea. Machy. (N. Y.), vol. 28, no. 10, June 1922, pp. 814–816, 4 figs. Characteristics of leather belting and charts for simplifying calculations.

Leather, Laboratory Tests. Method of Tests on Leather Belt and Laboratory Equipment, L. W. Arny. Belting, vol. 20, no. 5, May 1922, pp. 31–32, 2 figs. How research into many perplexing problems is conducted by leather belting exchange foundation at Sibley College of Mech. Eng., Cornell.

Steel. Machinery Driven by Steel Belt, John D. Knox. Iron Trade Rev., vol. 70, no. 16, Apr. 20, 1922, pp. 1114–1116, 6 figs. Endless steel bands rolled from seamless tubing have wide application for transmitting power; slippage is overcome by facing pulleys with cork; relation of pulley speeds is discussed.

BLAST-FURNACE GAS

Cleaning Methods, Comparison. Gas Cleaning Methods Compared, N. H. Gellert. Iron Trade Rev., vol. 70, no. 20, May 18, 1922, pp. 1401–1406, 4 figs. Analysis of relative merits of dry and wet cleaning systems with formulas and tabular data supplying specific information; concludes that hot-cleaned gas effects a fuel economy.

Value of Clean. The Value of Clean Blast-Furnace Gas, N. H. Gellert. Mech. Eng., vol. 44, no. 5, May 1922, pp. 305–310, 3 figs. Savings resulting from use of clean gas in hot-blast stove and boiler operation. Superiority of dry cleaning over wet cleaning. Possibilities held out by electrical cleaning process.

Washing Losses. Analyzing Gas Washing Losses, H. T. Watts. Iron Trade Rev., vol. 70, no. 17, Apr. 27, 1922, pp. 1179–1181. Causes of heat losses in wet washing of blast furnace gas are outlined and amount of loss is calculated. Effects of stoves and vapor content are considered.

BLAST FURNACES

Charging. Notes on Blast Furnace Filling, D. E. Roberts. Engineering, vol. 113, no. 2941, May 12, 1922, pp. 599–603, 16 figs. Relative advantages of skip and bucket systems. Paper read before Iron & Steel Inst.

Filling. Notes on Blast-Furnace Filling, D. E. Roberts. Iron & Steel Inst. advance paper no. 9, meeting May 1922, 17 pp., 14 figs. partly on supp. plates. Description of skip and bucket methods of mechanical charging.

Lining Failures. Lining Failures Caused by Zinc, P. O. Menke. Iron Trade Rev., vol. 70, no. 20, May 18, 1922, pp. 1409–1410. This element in ores and limestone causes deterioration; effect is accumulative; water cooling above mantle seems to accelerate action; recommends heavier plates.

Remodeling. Rebuilds Eastern Blast Furnace, Richard Peters, Jr. Iron Trade Rev., vol. 70, no. 18, May 4, 1922, pp. 1258–1260, 4 figs. Thomas Iron Co. in modernizing historic plant at Hokendauqua, Pa. completely reconstructs stack no. 3; new equipment includes buildings, power plant and auxiliary apparatus; provision is made for future expansion.

BOILER FEEDWATER

Characteristics. The Story of Feed Water, M. F. Newman. Combustion, vol. 6, no. 6, June 1922, pp. 273-278, 5 figs. Impurities which cause trouble and suggested plan for feedwater.

Heating. Heating Feedwater by Steam From Turbines (Réchauffage de l'eau d'alimentation par prélèvement de vapeur aux turbines), R. de Kergaradec. Génie Civil, vol. 80, no. 17, Apr. 29, 1922, pp. 380-383, 2 figs. Makes calculations of savings effected, draws attention to some modifications required in boiler equipment.

BOILER FIRING

Oil-Firing System. The New Körting Oil Firing System (Neue Körting-Oelfeuerungen), Pradel. Petroleum, vol. 18, no. 13, May 1, 1922, pp. 481-486, 5 figs. Describes new steam jet or compressed air centrifugal atomizer recently put on market, and gives examples of its application.

Oil-Fuel. Oil Firing Sixty-four Boilers at Amoskeag. Power, vol. 55, no. 24, June 13, 1922, pp. 920-923, 3 figs. Features of installation at Manchester, N. H., which eliminates factors of coal firing objectionable in textile plant.

BOILER MAKING

Babcock & Wilcox French Plant. The Works of the French Babcock & Wilcox Co., Engineering, vol. 113, no. 2944, June 2, 1922, pp. 674-676, 7 figs. Description of plant covering 153,000 sq. yd. and containing 8 large buildings in which all operations are carried on.

BOILER OPERATION

Colfax Station. Boiler-Room Performance and Practice of the Colfax Station, Duquesne Light Company, C. W. E. Clarke. Mech. Eng., vol. 44, no. 5, May 1922, pp. 295-300, 8 figs. Description of plant of Duquesne Light Co., Cheswick, Pa., and some details of its operation and performance.

Efficiency. New Practical Industrial Method of Using Boilers (Nouvelle méthode industrielle pratique pour l'exploitation rationnelle des générateurs de vapeur), H. Carra. Chaleur & Industrie, vol. 3, nos. 23 and 24, Mar. and Apr. 1922, pp. 1049-1056 and 1158-1164, 9 figs. Discusses essentials of combustion and analysis of losses in heat production, measurement and control of these losses, leading to quasi-automatic control.

BOILER PLANTS

Production Cost. Production Costs and Boiler Plants, W. S. Johnston. Combustion, vol. 6, no. 6, June 1922, pp. 285-288. General discussion of expenses with suggestions for plant enlargements or renewals as deduced from modern achievements.

BOILER PLATES

Cracks. Formation of Cracks in Boiler Plates, B. Strauss and Ad. Fry. Forging & Heat Treating, vol. 8, no. 5, May 1922, pp. 225-229, 23 figs. Force influence figures developed by new etching method permit recognition of brittleness. Tests show that rolled plates should be finished at as high a temperature as possible. Translated from Stahl und Eisen, Aug. 18, 1921.

BOILER TUBES

Charcoal Iron. Installing and Maintaining Charcoal Iron Locomotive Boiler Tubes, C. H. Woodroffe and C. E. Lester. Ry. Mech. Engr., vol. 96, no. 5, May 1922, pp. 274-278, 13 figs. Use of welding in tube work, with particular reference to recommended maintenance practice in enginehouses. Describes effective flue-shop equipment and layout.

BOILERS

Centralized Combustion Control. Centralized Combustion Control for Boilers. Power, vol. 55, no. 20, May 16, 1922, pp. 771-774, 8 figs. Operation of automatic control for bank of boilers thereby maintaining constant character of combustion at all loads.

Developments. Recent Boiler Developments, V. Z. Caracristi. Steam, vol. 29, no. 5, May 1922, pp. 123-128. Removal of limitations as to pressure, size and output by recent development; covers any present-day power.

Seams, Efficiency of. Calculating the Efficiency of Boiler Seams, R. J. Finch. Boiler Maker, vol. 22, no. 5, May 1922, pp. 126-129, 5 figs. Tables reduce chance for error and facilitate work; points where failure is likely to occur.

Steam Heating. Water Returns to Steam Heating Boilers. Am. Soc. Heating & Vent. Engrs. Jl., vol. 28, no. 3, Apr. 1922, pp. 328-342, 1 fig. Proper return connections to heating boilers when set in battery of two or more, and application of check valves. Report prepared by representatives of engineering staffs of insurance companies writing steam-boiler insurance in United States.

[See also LOCOMOTIVE BOILERS, MARINE BOILERS.]

BOILERS, WATER-TUBE

Spearing. Spearing Water-tube Boiler. Elec. Rev., vol. 90, no. 2320, May 12, 1922, pp. 652-655, 6 figs. Characteristics including sectional headers, downcomer pipes, reservoir mud drum.

Vertical. Thermal Principles in the Construction of Modern Vertical Water-Tube Boilers (Bau- und wärmetechnische Grundsätze für den Bau neuzeitiger Steilrohrkessel), Berner. Wärme, vol. 45, no. 11, Apr. 7, 1922, pp. 165-169, 14 figs. Discusses these principles in connection with a Muller boiler, including circulation of water and steam, superheating, boiler settings, results of efficiency tests.

BRASS

Cartridge, Physical Properties of. Physical Properties of Cartridge Brass, C. Upthegrove and W. G. Harbert. Trans. Amer. Inst. Min. & Met. Engrs. issued with Min. & Metallurgy, May 1922, no. 1161-N, 10 pp., 8 figs. Some data bearing on effect of anneal previous to final reduction or rolling on hardness.

Corrosion and Dezincing. Selective Corrosion and Dezincing of Brass Parts (Selektive Korrosionen und Entzinkungerscheinungen an Messingteilen), F. v. Wurstemberger. Zeit. für Metallkunde, vol. 14, nos. 1 and 2, Jan. and Feb. 1922, pp. 23-29 and 59-69, 26 figs. Explains dezincing as a double process of an anodic dissolution of metal and a cathodic precipitation of copper; elimination of corrosion.

BRONZES

Manganese. Occurrence of Blue Constituent in High-strength Manganese Bronze, E. H. Dix, Jr. Trans. Amer. Inst. Min. & Met. Engrs. issued with Min. & Metallurgy, May 1922, no. 1158-N, 16 pp., 19 figs. Study of this feature discovered during investigation of high-strength manganese bronze by Eng. Division of Air Service.

Manganese Bronze in Engineering Work. Iron Age, vol. 109, no. 22, June 1, 1922, pp. 1513-1515, 5 figs. How it is made in large foundry; its properties in castings and rolled form; typical installations.

C

CALCULATING MACHINES

Mercedes-Euclid. A Machine That Thinks (Mitteilungen aus der Praxis). Technische Blätter, vol. 12, no. 20, May 20, 1922, pp. 204-206, 3 figs. Describes Mercedes-Euclid arithmetical machine and gives details of its operations in adding, subtracting and multiplication.

CAR WHEELS

Cast-Iron. Metal for Cast Iron Car Wheels, Y. A. Dyer. Iron Age, vol. 109, no. 22, June 1, 1922, pp. 1504-1506. Three distinct compositions embodied in one mass: white, gray and mottled; care necessary in blending cupola charges.

Chilled-Iron. An Investigation of the Properties of Chilled Iron Car Wheels, J. M. Snodgrass and F. H. Guldner. Univ. Ill. Bul. no. 129, vol. 19, May 1, 1922, pp. 9-95, 44 figs. Requirements of car wheels and tests of this type.

Thermal Stresses in Chilled Iron Car Wheels, G. K. Burgess and R. W. Woodward. Technologic Papers of Bur. of Standards, no. 209, Mar. 18, 1922, pp. 193-226, 26 figs. Stresses calculated from strain-gage measurements.

Cushion, Flanged. Flanged Cushion Wheel of New Design. Elec. Traction, vol. 28, no. 5, May 1922, pp. 420-421, 4 figs. New type of Mead cushion wheel for passenger coaches has features which have proven to be practical.

Tire Rolling. A New Departure in Tire Rolling. Ry. Gaz., vol. 36, no. 18, May 5, 1922, pp. 735-736, 6 figs. Describes system for production of railway tires which has recently been installed by leading firm of manufacturers.

CARBURETORS

Setting for Airship Engine. The Determination of a Carburetor Setting for the Liberty Engine for Dirigible Use. Air Service Information Circular, vol. 4, no. 311, Mar. 15, 1922, 8 pp., 2 figs. Results of test to develop a carburetor setting for Liberty 12-cylinder engine adapting it for dirigible service.

CARS, FREIGHT

Corrugated Steel Roof. A Self-Supporting Corrugated Steel Freight Car Roof. Ry. Age, vol. 72, no. 19, May 13, 1922, pp. 1129-1130, 2 figs. Describing new design placed on market by Sharon Pressed-Steel Company.

CASE-HARDENING

Carburizing. Recommended Practice in Carburizing, S. P. Rockwell. Am. Mach., vol. 56, no. 22, June 1, 1922, pp. 811-812. Suggestions for selection of carburizing material; methods of testing it; best materials for different kinds of work; design and use of carburizing pots. Paper read before Am. Gear Mfrs. Assn.

Penetrability of Carbon. The Penetration of Carbon Into Metals and Mixed Crystals of Iron (Ueber die Diffusion des Kohlenstoffs in Metalle und die Mischkristalle des Eisens), Gustav Tammann. Stahl u. Eisen, vol. 42, no. 17, Apr. 27, 1922, pp. 654-658, 9 figs. Coefficient of penetrability of carbon and effect of molybdenum, cobalt, manganese, tungsten, etc., on depth of penetration.

Steel, Quality of. Effect of Quality of Steel on Case-Carburizing Results, H. W. McQuaid and E. W. Ehn. Forging & Heat Treating, vol. 8, nos. 5-6, May and June, 1922, pp. 243-247, 274-278, 46 figs. Effect of non-metallic impurities and alloy elements on final results in hardening of case-carburized steel. Paper presented Feb., 1922 at A.I.M.E.

CAST IRON

Carburization. A Study of Carburization in Manufacture of Synthetic Cast Iron, C. E. Williams and C. E. Sims. Amer. Electrochem. Soc., advance paper, no. 13, meeting Apr. 27-29, 1922, 8 figs. Investigation of factors which influence carburization.

Chemical Composition. Cast Iron and Its Chemical Composition, O. Smalley. Foundry Trade Jl., vol. 25, nos. 298 and 299, May 4 and May 11, 1922, pp. 323-326, and 343-345, 16 figs. Study of little known elements in cast iron which have kept mechanical characteristics from being controlled. Paper read before Inst. of British Foundrymen.

Electrical Melting. Melts Gray Iron Electrically, W. E. Cahill. Foundry, vol. 50, no. 10, May 15, 1922, pp. 420-421. Cheap current makes it profitable to melt both iron and steel for castings electrically; power consumption figures given; iron produced has uniformly fine grain.

Synthetic, Carburization of. Carburize Synthetic Cast Iron, Clyde E. Williams and C. E. Sims. Foundry, vol. 50, no. 10, May 15, 1922, pp. 390-393 and 422, 8 figs. Experiments made in introducing commercial forms of carbon, details of operation and results; effects of slags and various elements contained in iron are studied.

CASTING

Continuous. Improving Casting Methods in Steel Works (Amélioration des procédés de coulée dans une aciérie), Lucien Dujardin. Outillage, Tome 256, no. 16, Apr. 22, 1922, pp. 475-477, 6 figs. Discusses continuous casting in order to increase production, and describes foundry arrangements necessary.

CASTINGS

Centrifugal. Producing Centrifugal Castings, Leon Cammen. Iron Trade Rev., vol. 70, no. 17, Apr. 27, 1922, pp. 1188-1193, 3 figs. Methods of making hollow metal objects and machine used are described. Uniform cooling of poured metal makes manufacture of thin tubes possible; believes process may be applied to plate making. Presented at A.S.M.E. Spring Meeting May 1922.

CEMENT

Alumina. Alumina Cement; Its Development, Use and Manufacture, Henry S. Spackman. Eng. News-Rec., vol. 88, no. 20, May 18, 1922, pp. 831-834. History and properties of high strength, quick setting cement now being produced commercially in France.

CEMENT MANUFACTURE

Clinker Burning. Heat Distribution in Burning Cement Clinker, Elliott H. Whitlock and Charles E. Burgoon. Concrete, vol. 20, no. 5, May 1922, pp. 111-118, 14 figs. Study of variable conditions with view to improving efficiency of operation from engineering standpoint.

Segregation. Segregation, Charles Catlett. Concrete, vol. 20, no. 5, May 1922, pp. 119-124. Results of original investigation and segregation as applied to cement industry.

CENTRAL STATIONS

Calumet Plant, Chicago. Calumet to Reinforce Industrial Section of Chicago System, Elec. World, vol. 79, no. 22, June 3, 1922, pp. 1111-1114, 6 figs. New station of Commonwealth Edison Co. has 15,089 sq. ft. boilers with integral economizers and forced-draft chain grates; steam is bled from prime movers for heat balance. See also Elec. Ry. Jl., vol. 59, no. 22, June 3, 1922, pp. 897-901, 6 figs.

Calumet Station, Commonwealth Edison Co. Power, vol. 55, no. 22, May 30, 1922, pp. 842-850, 10 figs. Initial installation, 60,000 kw. Steam supplied to turbines at 300 lb. pressure and 200 deg. superheat. Seven 15,089 sq. ft. boilers designed for 350 lb. and 250 deg. superheat. Other features of installation.

Economic Operation. Economic Production of Power and the Technical Side of Super-Central Stations (La production économique de l'énergie et la technique des super-stations centrales), A.-R. Garnier. Technique Moderne, vol. 14, nos. 2, 3 and 4, Feb., Mar. and Apr. 1922, pp. 63-69, 106-112 and 167-170, 9 figs. Feb.: Modern tendencies in mass production of power, including steam driving of turbines, superheat, handling of fuel, air preheating. Mar.: Technical aspects of superpower stations, including simplification of conduits, increase in power per unit, turbines and their characteristics. Apr.: Discusses electrical equipment, especially close connection between turbine and generator.

Operation. Performance of Equipment and Trends in Station Practice. Elec. World, vol. 79, no. 20, May 20, 1922, pp. 1033-1035, 1 fig. Analysis of turbine outages and operating data for powdered-fuel, Diesel and oil plants constitute important part of report of N.E.L.A. Com. on Prime Movers this year.

Superpower. The Gennevilliers Central Station (La Centrale de Gennevilliers). Special Number of Chaleur & Industrie, pp. 14-54, 29 figs. Details of superpower station constructed by Union d'Électricité, especially boiler-room equipment, condensers, economizers, boilers, etc.

CHAIN DRIVE

Tooth Grinding. Grinding Inverted Tooth Chain Wheels. Eng. Production, vol. 4, no. 85, May 18, 1922, pp. 474-475, 4 figs. Outline of method by which flanks of inverted-tooth chain-wheel teeth may be accurately ground to correct dimensions and angles, and machinery for grinding wheels of any pitch, width, and number of teeth.

CHARTS

Construction. Principles of Constructing Charts (Coup d'oeil sur les principes fondamentaux de la nomographie), M. d'Ocagne. Révue Générale des Sciences, vol. 33, no. 8, Apr. 30, 1922, pp. 230-239, 9 figs. Discusses cases in which more than three variables can be reduced to graphic presentation on a plane.

CHROMIUM STEEL

Spontaneous Passivity. Spontaneous Passivity of Chromium Steels (Die spontane Passivität der Chromstähle), G. Tammann. Stahl u. Eisen, vol. 42, no. 15, Apr. 13, 1922, pp. 577-578, 1 fig. Behavior of chromium steels and electrolytes and protective effect of chromium.

CLUTCHES

Magnetic. Magnetic Clutches for Machine Driving, C Sylvester. Eng. Production, vol. 4, no. 86, May 25, 1922, pp. 491–492, 2 figs. Notes on their design application and working

COAL

Combustion. The Combustion of South African Coals in Boiler Furnaces, E. P. Reim. So. African Eng., vol 33, nos 3 and 4, Mar. 31 and Apr. 29, 1922, pp. 40, 73 75 Mar. 31: Origin and mode of formation of coal, impurities. Apr. 29: Describes combustion characteristics. From paper read before Chem., Metallurgical & Min. Soc. of So. Africa.

Recovery from Ashes. Recovering Coke and Coal From Ashes Die Wiedergewinnung von Koks and Kohle aus Feuerungsruckständen). F. Schulte. Glauckauf, vol. 58, no. 18, May 6, 1922, pp 534–537, 5 figs. Recovery systems of Weber, Hessel, Schilde, and Ullrich, and their advantages and disadvantages.

Spontaneous Combustion. Microscopical Examination of Batt, James Lomax. Colliery Guardian, vol. 123, no. 3199, Apr. 21, 1922, pp. 975–977 (includes discussion), 21 figs. Microscopical research carried on for describing the various forms of pyrites or iron disulphide found in coal, its origin and probable effects in relation to spontaneous combustion. Paper read before Manchester Geological & Min. Soc See also Iron & Coal Trades Rev., vol. 104, no. 2825, Apr. 21, 1922, pp. 577–578.

COAL HANDLING

Conveyor, Shaking. Horizontal Reciprocating Conveyor and Screen on a New Principle, Alphonse F. Brosky. Eng. & Indus. Management, vol. 7, no. 13, May 4, 1922, pp. 407–410, 10 figs. This device is manipulated by revolving weights and spring supports whereby compound motion is obtained and coal is caused to travel forward continuously. By duplicating opposing parts useless vibration is prevented.

Conveyors. Tells How Conveyor Saved Money for Plant, A. MacLean. Black Diamond, vol. 68, no. 18, May 6, 1922, p. 429, 1 fig. Description of Barber-Greene Conveyor which operated for five years without requiring repairs and handles coal and ashes at thirteen cents a ton, including labor.

Docks. The Coaling Devices of the Suisted Elevator Company at the Victoria and Albert Docks, Geo. F. Zimmer. Eng. & Indus. Management, vol. 7, no. 14, May 18, 1922, pp. 435–440, 7 figs. Description of machines designed by Suisted Elevator Co. and ultimate successful accomplishment.

Industrial Plants. Coal and Ash Conveying for Boiler Rooms (Bekohlung und Entaschung im Kesselbetriebe), R. Dub. Fördertechnik u. Frachtverkehr, vol. 15, nos 9 and 10, Apr. 28 and May 12, 1922, pp. 123–127 and 138–144, 16 figs. Apr. 28: Storing and conveying of coal from factory coal pile by means of conveyors, cranes, etc. May 12: Mechanical feeding of coal to boiler house in a number of large central stations.

Power. Handling Coal by Power, James B. Hayden. Combustion, vol. 6, no. 6, June 1922, pp. 268–272, 6 figs. Desirability of mechanical devices and suggestions for planning same.

COKE

Blast Furnace and Foundry. Testing of Coke for Blast Furnace and Foundry Purposes (Vorschläge zur Prufung des Kokses fur Hochofen- und Giessereizwecke), Heinrich Koppers. Stahl u. Eisen, vol. 42, no 15, Apr. 13, 1922, pp. 569–573, 4 figs. Properties of metallurgical coke, ease of combustion, porosity, and different requirements of coke for blast furnaces and foundries.

COKE OVENS

Piette. Piette Coke Oven Consumes a Little Over One-Third of the Heat in Its Gases, Hector Prud'-Homme. Coal Age, vol. 21, no. 24, June 15, 1922, pp. 1003–1005, 1 fig. Makes almost 70 per cent of coal into coke, about 5½ lb. of ammonia, 7 gal. of tar and 3½ gal. of benzine; long oven life anticipated.

COMBUSTION

Spontaneous. Spontaneous Combustion and Friction, Walter L. Wedger. Fire & Water Eng., vol. 71, no. 15, Apr. 12, 1922, pp. 603 604 and 614. Notes on substances subject to spontaneous ignition; coal, fibers and wood charcoal said to be very susceptible; friction fires caused by foreign substances.

COMPRESSED AIR

Motive Power, as. Compressed Air as Motive Power (Energiewirtschaft beim Pressluftbetriebe), A. Hinz. Glückauf, vol 58, no. 20, May 20, 1922, pp. 581 589, 4 figs. Discusses storing of compressed air for power purposes and examines mathematically process in air compressors, piston compressors and turbo-compressors, and determines their efficiency.

Pneumatic Mail Dispatch. Pneumatic Tubes in the United States for Mail—German Types (Rohrposten für Briefbeutel in den Vereinigten Staaten von Nordamerika, deutsche Bauarten), Schwaighofer. Organ für die Fortschritte des Eisenbahnwesens, vol 77, no. 5, Mar. 1, 1922, pp. 65 70, 5 figs. Discusses postal tube services in Chicago, New York, Philadelphia and St. Louis, and makes comparison with German parcel tubes.

COMPRESSORS

Ammonia. See AMMONIA COMPRESSORS.

CONCRETE

Abrasion Test. New Laboratory Abrasion Test for Concrete, C. H. Scholer. Cement & Eng. News, vol 34, no. 4, Apr. 1922, pp. 23 24, 4 figs. Test being developed by Engineering Experiment Station of Kansas State Agricultural College, 9-in spheres of concrete cast and tested after proper aging and curing. Tested in standard brick rattler using standard abrasive charge.

Central-Plant-Mixed. Central-Plant-Mixed Concrete Tested for Safe Haul, James W. Brooks. Contractors' & Engrs.' Monthly, vol 4, no 4, Apr. 1922, p. 48. Description of tests made to determine safe maximum length of haul.

Fastening Machinery to. Fastening Machinery to Concrete, G. H. Radebaugh. Brick & Clay Rec., vol. 60, no. 11, May 30, 1922, pp. 848–851, 12 figs. Practices which have been found successful in working with hard concrete; procedure outlined step by step.

COPPER ALLOYS

Cupro-Nickel, Cold-Work and Recrystallization. The Internal Mechanism of Cold-Work and Recrystallisation in Cupro Nickel, Frank Adcock. Metal Industry (Lond.), vol. 20, nos. 16 and 17, Apr. 21 and 28, 1922, pp. 372–374 and 392–394, 21 figs. Experiments for gathering information on process of cold-work and recrystallization of metals.

CORE OVENS

Electric vs. Oil-Fired. Core-oven Tests, F. L. Wolf and A. A. Grubb. Am. Inst. Min. & Met. Engrs. Trans. advance paper, no. 1152-N, Apr. 1922, 13 pp., 2 figs.; also (abstract) in Min. & Metallurgy, no. 184, Apr. 1922, pp. 37–38, 2 figs. Describes tests to obtain information regarding costs, efficiency, etc. of baking cores in oil-fired oven and two electric ovens installed in 1920 in core room of Ohio Brass Co. Power and fuel costs favor oil, while quality and uniformity of bake, core losses, convenience and cost of tending, favor electricity.

CORROSION

Ferrous Metals. Corrosion of Ferrous Metals, Robert Abbott Hadfield. Engineering, vol. 113, no. 2936, Apr. 7, 1922, p. 419. Preparation of various ferrous metals used in corrosion research of Instn. Civ. Engrs. together with their physical and mechanical properties, and general considerations on subject of corrosion. (Abstract.) Paper read before (British) Instn. Civ. Engrs.

Prevention by Deactivation of Water. Control of Corrosion by Deactivation of Water, Frank N. Speller. Franklin Inst. Jl., vol. 193, no. 4, Apr. 1922, pp. 515–542, 13 figs. Outline of present status of corrosion prevention by deactivation and deaeration of water.

Sea-Water. Reducing Corrosion by Sea Water, Robt. Hadfield. Iron Trade Rev., vol. 70, no. 21, May 25, 1922, pp. 1481–1483, 3 figs. British conduct extensive investigation to determine best type of steel for under-water structural work; non-rusting steel containing 12 to 14 per cent chromium is found to be most satisfactory.

Water-Carrying Vessels, Prevention. Corrosion and Its Prevention in Vessels Carrying Water, J. R. McDermet. Am. Soc. Heat. & Vent. Engrs., vol. 28, no. 4, May 1922, pp. 407–416. Suggestions for reducing corrosion in water piping, boiler economizers, boilers, steam piping or water tanks.

COUPLINGS

Flexible. Universal Joints and Flexible Couplings; Their Kinds and Uses on Boats, Wm. Atkin. Motor Boat, vol. 19, no. 11, June 10, 1922, pp. 15–17, and 28, 12 figs. Consideration of necessity for flexible couplings.

CRANES

Electric. Electric Cranes At the Swiss Federal Railway Shops at Bellinzona. Engineering, vol. 113, no. 2943, May 26, 1922, pp. 653–654, 4 figs. Arrangement of two 80-ton electric traveling cranes for handling heavy electric locomotives.

Harbor. Cranes and Tipping Wagons for Loading and Unloading Ships (Kran und Kipper als Mittel zum Laden und Löschen von Wasserfahrzeugen), Wintermeyer. Fördertechnik u. Frachtverkehr, vol. 15, no. 8, Apr. 14, 1922, pp. 110–114, 11 figs. Discusses various types of cranes, electric drive, conveying platforms, etc.

Selection and Development of Double Cranes for Harbors (Über Wahl und Ausbildung von Doppelkranen fur Häfen), E. Krahnen. Fördertechnik u. Frachtverkehr, vol. 15, no. 8, Apr. 14, 1922, pp. 114–116, 8 figs. Describes new type of crane to expedite loading and unloading of ships. Combined Sction of two neighboring cranes.

Wharf, Hydraulic. Hydraulic Wharf Cranes. Shipbldg. & Shipg. Rec., vol. 19, no. 21, May 25, 1922, p. 684, 1 fig. Description of six 30-cwt. luffing cranes for port of London authority.

CUTTING TOOLS

Action of. The Action of Cutting Tools, E. G. Coker and K. C. Chakko. Engineering, vol 113, no. 2940, May 5, 1922, pp. 564 569, 18 figs. Investigation of most efficient action of various tools for shaping metals and means of determining stresses set up.

Experiments. An Account of Some Experiments on the Action of Cutting Tools, E. G. Coker. Engineer, vol. 133, no. 3462, May 5, 1922, pp. 503 505, 12 figs. Means of studying stress distribution in cutting tools by polarized light

D

DETONATION

Study of. The Background of Detonation, Stanwood W. Sparrow. Nat. Advisory Committee for Aeronautics Tech. Notes, no. 93, Apr. 1922, 17 pp., 5 figs. Consideration of several features of detonation problem which, it is claimed, have received comparatively little attention.

DIESEL ENGINES

Beardmore-Tosi The Beardmore-Tosi Marine Diesel Engine. Engineering, vol. 113, no. 2938, April 21, 1922, pp. 488–489, 4 figs. Description of main engines of single-screw motorship Pinzon

Marine. North British Diesel Machinery for 2,000-ton Twin-Screw Vessels. Mar. Engr. & Naval Architect, vol. 45, no. 536, May 1922, pp. 204–206 and 207, 3 figs. Two sets of engines for British India Steam Navigation Co. vessels Dumra and Dwarka, developing 500 b.hp. on each of twin shafts and built by North British Diesel Engine Works, Glasgow.

Merchant Marine and Electrical Industries. Use of Diesel Engines in the Merchant Marine and in Electrical Industries (Les applications du moteur Diesel dans la marine de commerce et leurs conséquences au point de vue de l'industrie électrique), Yves Le Gallou. Révue Générale de l'Électricité, vol. 11, no. 15, Apr. 15, 1922, pp. 535–543. Conditions under which Diesel engines are used on board ship, for propulsion and for driving auxiliaries; its effect on development of electrical industry.

Power Plants. Diesels at Southend. Elec. Times, vol. 61, no. 1594, May 4, 1922, pp. 429–430, 3 figs. Rapid increase in demand for electric power met by successive installations of Diesel engines.

Power Plants, Application in. Diesel Engines and Examination into Their Economic Application (Dieselmotoren, Eine Untersuchung über ihre wirtschaftliche Verwendung), Alfred Büchi. Schweizerische Bauzeitung, vol. 79, nos. 18 and 19, May 6 and 13, 1922, pp. 230–235 and 239–243, 11 figs. May 6: Compares hydroelectric with Diesel-electric power generation. May 13: Discusses Diesel engine installation in connection with water power works and gives cost calculation for water power only and water power with Diesel engines.

Submarine Type for Power Plants. Submarine Diesel Engines at Southend, Elec. Rev., vol. 90, no. 2321, May 19, 1922, pp. 688–690, 3 figs. Description of engines taken from dismantled German submarines and generating units which they operate.

Water-Works Power. Diesel Engines to Furnish Power for Water-Works, W. DeWitt Vosbury. Eng. News-Rec., vol. 88, no. 19, May 11, 1922, pp. 793–794, 2 figs. New station at Gloucester, N. J. to be equipped with motorized pumps and high-economy, oil-engine-driven generators.

E

ELECTRIC COMMUNICATION

Aurora, Effects of. Effects of Aurora on Telegraphs, Telephones and Wireless in New Zealand. Telegraph & Telephone Age, no. 11, June 1, 1922, pp. 248–249. Report by A. Gibbs, deputy chief telegraph engr., on effects of auroral phenomenon generally, and those during exceptionally brilliant display.

ELECTRIC DRIVES

Installation. Protected Motor Service, T. W. C. Hartmann. Elec. Rev. & Indus. Engr., vol. 80, no. 5, May 1922, pp. 227–228, 257 and 262, 4 figs. Recent installation at Keystone Spring Works where electric drive has speeded up machine production.

ELECTRIC FURNACES

Carbon Steel. Electric Furnace Practice on Carbon Steel, L. J. Barton. Western Machy. World, vol 13, nos. 4 and 5, Apr. and May 1922, pp. 134–137 and 173–175, 2 figs. April: Basic Operation; Two-slag practice in production of electric steel, with details of charging, melting down, chemical and other factors. May: Slagging and details of reducing period. Effects of high lime temperature tests. Finishing of heat

Cast-Iron Production. Cast Iron as Produced in the Electric Furnace, and Some of Its Problems, George K. Elliott. Am. Electrochem. Soc. advance paper, no 9, for meeting Apr. 27–29, 1922, pp. 75–87. Review of literature of electric-furnace cast iron. Discusses conditions favorable to electric furnace, and expresses preference for duplex process with basic-hearth electric furnace. Describes desulphurization and deoxidization; etc.

Electric Furnace Iron and Steel. Intermittent and Alternating Operations, W. E. Cahill. Am. Electrochem. Soc. advance paper, no. 6, for meeting Apr. 27 29, 1922, pp. 49–54. In Treadwell, Alaska, cast iron is made more cheaply in electric furnace than in cupola. Analyses figures show that from charges of all-scrap cupola-melted iron electric furnace produces metal of greatly reduced sulphur content.

Fiat. The Fiat Electric Furnace. Engineering, vol. 113, no. 2936, Apr. 7, 1922, pp. 421–422, 5 figs. partly on p. 424. Three-phase type, having a hearth slightly conductive, neutral and connected to earth. One of characteristic features is the Fiat economizer, or electrode holders.

Italian. Italian Electric Furnaces in Brazil (Forni elettrici italiani nel Brasile), Ettore Thover. Forno Elettrico, vol. 3, no. 9–10, Sept. 15-Oct. 15, 1921, pp. 115–119, 4 figs. Describes the Bassanese electric furnace plant at Juiz de Fora (Minas Geraes) having four 3-ton 400 kw. furnaces.

Metal-Melting. An A.C. Metal Melting Furnace (Ein elektrischer Metall-Schmelzofen für den Anschluss an Drehstrom), E. Fr. Russ. Elektro-

technische Zeit., vol. 43, no. 15, Apr. 13, 1922, pp. 497–499, 7 figs. Its development and practical application; can be directly connected to rotary current; furnace contains three electrodes allowing equal phase distribution.

Non-Ferrous. Metal Electric Furnaces, A. Glynne Lobley. Metal Industry (Lond.), vol. 20, nos. 14 and 15, Apr. 7 and 14, 1922, pp. 322–325 and 333–341 and (Discussion) 341–342, 6 figs. Examples of number of uses for electric furnaces not in iron and steel industry. Portion of report before Sheffield Section of Inst. of Metals.

Shaft and Open-Top. A Comparison Between Shaft and Open Top Furnaces in the Manufacture of Pig Iron Electrically from Iron Ore, R. C. Gosrow. Am. Electrochem. Soc., advance paper, no. 8 for meeting Apr. 27–29, 1922, pp. 63–74. Notes on stack and open-top type of furnace and combination open-stack type.

Types. Electric Furnaces and Electrometallurgy, Recent Patents (Les fours electriques et l'electrometallurgie d'apres les brevets recents), L. Jumau. Revue Générale de l'Électricité, vol. 11, nos. 12 and 13, Mar. 25 and Apr. 1, 1922, pp. 436–441 and 463–468, 11 figs. Mar. 23: Describes Foley induction, Greiner resistance, Ferron, Moore, and other furnaces. Apr. 1: Electrodes, electric furnaces used in manufacture of steel and production of oxides of nitrogen.

ELECTRIC LOCOMOTIVES

Condensing Turbine. The Ramsay Condensing Turbine Electric Locomotive. Engineer, vol. 133, no. 3456, Mar. 24, 1922, pp. 328–329, 2 figs. Characteristics of experimental locomotive built by Armstrong, Whitworth & Co., Ltd.: Length overall, 69 ft. 7 in., max. width, 8 ft. 3 in., total weight, including 2200 gal. water for cooling purposes and 4 tons coal, 130 tons 15 cwt.; tractive force, 22,000 lb., turbo-generator, 890 kw., at 3600 rev., voltage, 600. See also Ry. Rev., vol. 70, no. 19, May 13, 1922, p. 667.

Metropolitan Ry., London. 1,200-Hp. Electric Locomotives for the Metropolitan Railway. Engineering, vol. 113, nos. 2936 and 2938, Apr. 7 and 21, 1922, pp. 409–412 and 477–481, 32 figs. partly on supp. plate. Locomotives are 0-4-4-0 type and each have two bogie trucks of carriage type on which body is carried. Max. speed on non-stop runs is 60 mi. per hr., electric supply is at 500 to 600 volts on third-rail system, and insulated negative return rail is laid in center of track; motors are of standard series-wound type with commutating poles. Describes control gears.

ELECTRIC PLANTS

Lausanne, Switzerland. Electric Installations of the City of Lausanne (Les installations electriques de la ville de Lausanne), G. Canderay. Bul. Technique de la Suisse Romande, vol. 47, nos. 19, 21, 23, 24, Sept. 17, Oct. 15, Nov. 12 and 26, 1921, pp. 217–223, 7 figs., 241–248, 9 figs., 265–269, 8 figs. partly on pp. 270–272, 285–287, 3 figs., and vol. 48, nos. 6, 7 and 9, Mar. 18, Apr. 1 and 29, 1922, pp. 61–65, 5 figs., 73–78, 12 figs., and 103–105, 3 figs. partly on p. 102. Sept. 17: Discusses barrage of the Rhone and work connected with extension of plants. Oct. 15: Discusses work at Bois Noir; water header, turbines, alternators, transformers, etc. Nov. 12 and 26: Switching arrangements; servo-motors; cost details of construction work. Mar. 18: Describes transmission lines, poles, etc., also equipment of Pierre-de-Plan works. Apr. 1 and 29: Describes new Pierre-de-Plan works for receiving, transforming and distributing 50,000-volt current.

Waste-Fuel Utilization. Electricity from Limburg Waste Fuels (Electriciteitsopwekking uit Limburgsche afvalbrandstoffen), A. J. Ter Linden. Ingenieur, vol. 37, no. 15, Apr. 15, 1922, pp. 282–297, 26 figs. Use of low-grade fuels, brown coals, etc.; hand and mechanical stoking; results of tests that were made.

ELECTRIC RAILWAYS

Electrolysis and Inductive Interference. Effects of Electric Power Used for Traction, Chas. F. Scott. Ry. Elec. Engr., vol. 13, no. 4, Apr. 1922, pp. 113–116, 1 fig. Question of inductive interference and electrolysis as related to railway electrification.

Three-Coach Trains. Three-Coach Electric Trains of the London and North Western Railway. Tramway & Ry. World, vol. 51, no. 24, May 18, 1922, pp. 234–242, 29 figs. Description of suburban service, operating at 630 volts and several new and interesting features in connection therewith.

ELECTRIC WELDING, ARC

Structural Steel. Arc Welded Steel Building, B. C. Tracey. Welding Engr., vol. 7, no. 5, May 1922, pp. 24–25, 5 figs. Savings in time, labor and material; methods of making joints, welded joints pass tests.

The Arc Welding of Structurel Steel, E. S. Humphrys, Jr. Iron Age, vol. 109, no. 21, May 25, 1922, pp. 1422–1425, 7 figs. Tests made to determine reliability of welded joints and limiting conditions of various types of joints.

Utility. Utility Arc Welding. Engineer, vol. 133, no. 3458, Apr. 7, 1922, pp. 378–381, 8 figs. Describes what has been accomplished by small engineering firm by means of arc welding with considerable saving in time and money.

ELECTRICAL MACHINERY

Export Prospects for Latin America. Market Prospects for Electric Apparatus in Latin America and in Spain, Philip S. Smith. Elec. World, vol. 79, no. 15, Apr. 15, 1922, pp. 724–727, 4 figs. Opportunity in mining, agricultural and manufacturing fields. Status of power house, substation, transmission and railway electrification. Outlook for motor drive.

ENGINE HOUSES

Turntables. Railway Turntables. Ry. Engr., vol. 43, no. 508, May 1922, pp. 198–200, 5 figs. Technical consideration of energy required to move them and advantages of ball bearings for reducing friction.

EVAPORATORS

Vacuum, Marine Type. Vacuum Type of Evaporator Being Extensively Used on German Ships. Nautical Gaz., vol. 102, no. 19, May 13, 1922, p. 585. New device works automatically and requires very little watching. Has proved its efficiency on freighters. How operated in harbors.

EXHAUST STEAM

Utilization. The Utilization of Exhaust Steam from Electric Generating Stations, and Coal Economy, C. Ingham Haden. Instn. Elec. Engrs. Jl., vol. 60, no. 307, Mar. 1922, pp. 265–271 and (discussion) 273–286, 2 figs. Suggests combination of heat distribution with generation of electric current as possible means of using coal to better advantage, and proposes conversion of some of existing generating stations. Describes installations already carried out.

The Utilization of Waste Heat from Electrical Generating Stations, F. H. Whysall. Instn. Elec. Engrs. Jl., vol. 60, no. 307, Mar. 1922, pp. 271–272 and (discussion) 273–286, 1 fig. Suggestions based on author's personal experience of practical difficulties encountered.

F

FATIGUE

Failure By. Failure By Fatigue. Engineering, vol. 113, no. 2939, April 28, 1922, pp. 525–526. Doubts as to mathematical theory of elasticity; discussion and means of determining fatigue tendencies of material.

FERRONICKEL

Brittleness at Low Temperatures. On the Brittleness of Ferronickel at Low Temperatures (Étude de la fragilite des Ferronickels aux basses temperatures), P. Chevenard. Révue de Métallurgie, vol. 19, no. 4, Apr. 1922, pp. 209–214, 3 figs. Experiments to produce metal which would not become brittle at temperature of liquid air, to be used for accessories of liquid-air machines, and results.

FIRE ENGINES

Standardization. Standardization of Fire Engines (Zur Normung der Motorspritzen), Hupeden. Feuerwehrtechnische Zeit., vol. 10, no. 3, Mar. 20, 1922, pp. 31–38, 6 figs. Discusses pump construction, quantity of water handled, motor construction and specifications generally.

Tilling-Stevens. New Tilling-Stevens Fire Engines. Motor Transport, vol. 34, no. 898, May 15, 1922, pp. 581–582, 5 figs. Three new fire pump vehicles have just been completed at Maidstone Factory, comprising large and medium self-propelling chassis and lightweight trailer.

FIREBRICK

Testing. New Methods for Determining Compression Strength and Softening of Firebrick at High Temperatures (Neue Verfahren zur Bestimmung der Druckfestigkeit und Erweichung feuerfester Ziegel bei hoben Temperaturen). Tonindustrie-Zeitung, vol. 46, no. 57, May 16, 1922, pp. 561–563. Reviews present methods and shows that there is as yet no uniform method of testing.

FLIGHT

Soaring. Experiments on Soaring Flight (Études éxpérimentales sur le Vol a Voile), P. Idrac. Aerophile, vol. 30, nos. 1–2, 3–4 and 5–6, Jan. 1–15, Feb. 1–15 and Mar. 1–15, 1922, pp. 4–9, 35–44 and 67–76, 46 figs. Discusses prolonged flight by birds without movement of wings and theories advanced to explain it; tests made; irregularities in wind velocity; vertical component of wind velocity; makes caclulation from experiments.

The "First Experimental Congress for Motorless Flight." Flight, vol. 14, no. 19, May 11, 1922, pp. 273–274, 1 fig. French soaring and gliding competition.

FLOW OF OIL

Pipes. Flow of Oil in Pipes. Lubrication, vol. 8, no. 4, Apr. 1922, pp. 45–48, 1 fig. Investigation of properties of oil and their effects on flow through pipes.

FLUE-GAS ANALYSIS

Unburned-Gas Determination. Incomplete Combustion and Furnace Control (Unvollkommene Verbrennung und Feuerungskontrolle), D. Haarmann. Feuerungstechnik, vol. 10, no. 16, May 15, 1922, pp. 173–176, 1 fig. Shows that CO determination of flue-gas should be supplemented by analysis for unburned gases.

FORGING

Hydraulic Bulging. Hydraulic Bulging and Bending. Machy. (Lond.), vol. 20, nos. 497, 498 and 499, Apr. 6, 13 and 20, 1922, pp. 8–12, 42–45 and 75–77, 43 figs. Apr. 6: Manufacture of gramophone swan necks and horn elbows. Apr. 13: Manufacture of telephone receiver cases. Apr. 20: Tooling for production of motor side lamp.

FOUNDATIONS

Bracing. Caisson Cofferdam Foundation With Special Bracing, T. Kennard Thomson. Eng. News-Rec., vol. 88, no. 22, June 1, 1922, pp. 914–918, 6 figs. Deep cellar substructure in filled ground, First Nat. Bank of Jersey City; Caissons braced by built-up struts during excavation; toe wall holds caissons against sliding; waterproofing.

FOUNDRIES

Blast Meter, Use of. Use of a Blast Meter in Foundry Practice, Louis L. Vayda. Iron Age, vol. 109, no. 23, June 8, 1922, pp. 1581–1586, 5 figs. Measurement of air blast volume important in cupola control; methods of measurement.

Brass. Brass Foundry Equipment, William H. Parry. Metal Industry (N. Y.), vol. 20, no. 5, May 1922, pp. 179–180. List of materials and supplies required for brass foundry melting five tons of metal per day.

Electricity in. Foundry Employs Electricity for Melting and Annealing, Herbert R. Simonds. Iron Trade Rev., vol. 70, no. 22, June 1, 1922, pp. 1567–1570, 8 figs. Description of units employed by Eastern manufacturer shows electrical equipment affects economies.

Motor Castings. A New Canadian Motor Foundry Plant. Iron Age, vol. 109, no. 16, Apr. 20, 1922, pp. 1068–1070, 6 figs. How old plant was made into new one, designed with view to future expansion. Machine molding a feature in plant of Hiram Walker & Sons Metal Products Co., Ltd., Walkerville, Ont.

Textile Machinery. A New Textile Machinery Foundry. Iron Age, vol. 109, no. 22, June 1, 1922, pp. 1499–1503, 7 figs. Machine molding and machine sand handling are features; old foundry transformed into cleaning room.

FOUNDRY EQUIPMENT

Pneumatic Tools. Pneumatic Tools in Foundry Practice, Jas. W. Anderson. Compressed Air Mag., vol. 27, no. 6, June 1922, pp. 163–166, 9 figs. Increased production resulting from adoption.

FUEL ECONOMY

France. Reducing the Cost of Motive Power (Réduction des depenses de force motrice), Ch. Molette. Outillage, Tome 259, no. 19, May 13, 1922, pp. 604–605. Generally discusses question of efficiency and shows that in nearly all cases a saving of from 10 to 20 per cent can be effected.

N. C. & St. L. Ry. Keen Competition Key to Fuel Economy on N. C. & St. L. Ry., J. B. Hill. Ry. Rev., vol. 70, no. 20, May 20, 1922, pp. 701–705, 7 figs. Rivalry based on individual and divisional fuel performance records improves entire operation of railroad.

Wabash Railroad. How the Wabash Railroad is Organized for Fuel Economy, J. B. Hurley. Ry. Rev., vol. 70, no. 20, May 20, 1922, pp. 705–708. Practical supervision, individual performance records and monthly meetings result in large fuel saving.

FUELS

See AUTOMOBILE FUELS, COAL, COKE, GASOLINE, LIGNITE, OIL FUEL, PULVERIZED COAL.

FURNACES, BOILER

Air Preheaters. European Preheater for Furnace Air. Power, vol. 55, no. 16, Apr. 18, 1922, pp. 615–616, 3 figs. Describes type of air heater, known as Thermix, manufactured by Émile Prat-Daniel, Paris, which is said to be finding extensive employment in Europe.

FURNACES, ELECTRIC

See ELECTRIC FURNACES.

FURNACES, HOT-AIR

Developments. Recent Developments in Warm Air Furnace Heating, F. R. Still. Am. Soc. Heat. & Vent. Engrs., vol. 28, no. 4, May 1922, pp. 385–395, 5 figs. Valuable suggestions sponsored by Warm Air Furnace Code Committee, including formulas and charts and some facts about circulation stimulators.

FURNACES, METALLURGICAL

Low-Heat Gas-Fired. Furnaces Utilize Low Heat Gases, R. J. Weitlaner. Iron Trade Rev., vol. 70, no. 19, May 11, 1922, pp. 1332–1334, 6 figs. Application of split-flame principle and employment of regenerators similar to those used with open hearths enable German furnaces of recent design to operate efficiently on inferior grade fuels.

G

GAGES

Gage Blocks. Measurement of Primary Standards by the Interferometer Method. Machy. (Lond.), vol. 20, no. 503, May 18, 1922, pp. 189–193, 6 figs. Checking gage blocks by N. P. L. comparator; an extremely sensitive mechanical apparatus for testing accuracy of precision slip gages.

Gage-Block Comparator. Comparator for Checking Precision Gage-blocks, Franklin D. Jones. Machy. (N. Y.), vol. 28, no. 9, May 1922, pp. 689–693, 6 figs. Extremely sensitive mechanical apparatus, which has proved very effective at plant of Pratt & Whitney Co. for testing accuracy of precision gage blocks.

GAS

Low-Heat-Unit. Advantages of Low Heat Unit Gas, Edward L. Richa. Gas Age-Rec., vol. 49, no. 21, May 27, 1922, pp. 651–654, 659 and 660. Relative advantages to gas company and consumer of lower-heat-unit gas. Paper written for Southern Gas Assn. Annual Mtg.

GASOLINE

Water, in. Determination of Water in Gasoline as Received—Exposed to Atmosphere, to Humid Atmosphere, and Saturated with Water. Air Service Information Circular, vol. 4, no. 320, Mar. 15, 1922, 2 pp., 1 fig. Investigation to ascertain whether, sufficient amounts of water can be absorbed by gasoline to cause corrosion, and investigation of several methods for determining water in gasoline.

GEAR CUTTING

Hobbing Spur Gears. Cutting Spur Gears by Hobbing. Machy. (N. Y.), vol. 28, no. 9, May 1922, pp. 716–721, 5 figs. Setting up gear-hobbing machines; examples from practice; application of multiple-threaded hobs; cutting small pinions.

Internal Spur. Cutting Internal Spur Gears, F. D. Jones. Machy. (N. Y.), vol. 28, no. 10, June 1922, pp. 776–779, 8 figs. Milling internal gear teeth with formed cutters; generating teeth on gear shaper; use of form-copying gear planer.

Mass Production. Mass Production in Gear-Cutting, Joseph Horner. Engineering, vol. 113, nos. 2935, 2937, 2938, Mar. 31, Apr. 14, Apr. 21, 1922, pp. 379–380, 443–445 and 477, 5 figs. Discusses methods associated with mass production of all kinds of gears, embracing such matters as division of operations between roughing and finishing, mounting of several blanks in series when practicable, and use of multiple cutters.

Spur. Cutting Spur Gears on Gear Planers. Machy. (Lond.), vol. 20, no. 502, May 11, 1922, pp. 153–162, 18 figs. Use of machines operating with planing action and forming gear teeth by generating from rack-shaped cutter. Sunderland system of gear generation.

Turbine Reduction Gears. Turbine Reduction Gearing and its Production, J. H. Melloy. Engineer, vol. 133, no. 3462, May 5, 1922, pp. 495–496, 3 figs. Means of attaining greatest accuracy in cutting, thereby obtaining silence, and smooth running, (Abstract) read before North-Western Section of Instn. Mech. Engrs.

GEARS

Bevel. The Assembling of Bevel Gears, Charles H. Logue. Am. Mach., vol. 56, no. 16, Apr. 20, 1922, pp. 580–584, 14 figs. Adjustment of pinion and of gear produce different results. Gears should be cut with allowance for backlash. Bottoming of teeth.

The Gleason System of Bevel Gears, F. W. McMullen and T. M. Durkan. Am. Mach., vol. 56, no. 23, June 8, 1922, pp. 849–853, 8 figs. Quietness in operation, strength and durability considered; limiting undercut; preference for low pressure angle; pressure causes wear.

The Gleason Works System of Bevel Gears, F. E. McMullen and T. M. Durkan. Machy. (N. Y.), vol. 28, no. 10, June 1922, pp. 788–792, 8 figs. Description of Gleason improvement in design of form of tooth consistent with strength and wear.

New System of Bevel Gearing Developed by Recent Research, F. E. McMullen and T. M. Durkan. Automotive Industries, vol. 46, no. 20, May 18, 1922, pp. 1064–1068, 8 figs. Quietest form of tooth consistent with strength and durability. Addendum and dedendum for any pitch varies with ratio; usually different for pinion and gear. Pressure angle depends on number of teeth ratio. Paper read before Am. Gear Mfrs. Assn.

Chain. Chain Gearing. Machy. Market, no. 1124, May 19, 1922, pp. 23–25, 6 figs. Industrial applications. Facts about inverted-tooth type and larger sizes of roller chain and their uses.

Chattering. Nodal Arrangements of Geared Drives, J. H. Smith. Engineering, vol. 113, nos. 2936 and 2937, Apr. 7 and 14, 1922, pp. 438–440 and 467–469, 1 fig. Results of author's investigation of chattering of gearing. Deals with dynamics of geared drives; dynamically equivalent masses and shafts; equations of motion; effect of tooth-form irregularities. Results and general conclusions relating to critical speeds; simplification of geared drives; arranging periodicity of disturbing torques. Paper read before (British) Instn. Nav. Architects.

Comparator for Testing Teeth. Inspecting Gear and Gear Cutters at One Hundred Magnifications, Ralph E. Flanders. Iron Age, vol. 109, no. 17, Apr. 27, 1922, pp. 1137–1138 and 1183, 5 figs. Describes invention for use in connection with Hartness projection comparator for testing gear teeth. (Abstract.) Paper read before Am. Gear Mfrs.' Assn.

Helical. A Chart to Aid the Figuring of Helical Gears, W. C. Steuart. Am. Mach., vol. 56, no. 17, Apr. 27, 1922, pp. 630–633, 12 figs. Relation between elements of helical gears. Method of constructing "spiral" gear protractor. More rapid solution of problems in helical gearing.

Hot Rolling. The Hot Rolling of Gears, Reginald Trautschold. Forging & Heat Treating, vol. 8, no 5, May 1922, pp. 216–219, 2 figs. Recent developments in and perfecting of process for successful production of gears by rolling blanks heated to forging temperature. Economy of process. See also Blast Furnace & Steel Plant, vol. 10, no. 5, May 1922, pp. 270–273, 2 figs.

Hydraulic Transmission. Recent Types of Hydraulic Transmission Gear. Eng. & Indus. Management, vol. 7, no. 11, Apr. 6, 1922, pp. 323–327, 5 figs. Discusses main requisites of efficient hydraulic gear and describes Williams-Janney, Hele-Shaw, and Constantinesco systems.

Machining. Tooling Equipment for Ball Races, Camshaft and Cluster Gears. Machy. (Lond.), vol. 20, no. 504, May 25, 1922, pp. 225–229, 14 figs. Examples of concentrated tooling.

Production, Estimating. Estimating Modern Gear Production, Gustave E. Spies. Am. Mach., vol. 56, no. 22, June 1, 1922, pp. 799–804, 7 figs. Charts and a slide rule that make estimating easy; use of disk cutters and hobs; extra travel of cutters; examples of estimate sheets.

Proportions. Proportions of Industrial Gears, G. E. Katzenmeyer. Machy. (N. Y.), vol. 28, no. 10, June 1922, pp. 799–802, 4 figs. Formulas and tables which are used in developing standardized industrial gears.

Spur. Backlash in Hobber Spur Gears. Machy. (Lond.), vol. 20, no. 502, May 11, 1922, pp. 163–165, 5 figs. Amount of backlash recommended to provide for unavoidable inaccuracies in machining and heat-treatment.

Strength and Proportions. Strength and Proportion of Industrial Gears, G. E. Katzenmeyer. Am. Mach., vol. 56, no. 18, May 4, 1922, pp. 666–671, 7 figs. Charts for determining strength of industrial gears. Formulas and symbols used and practical examples.

Teeth, Grinding. Gear Tooth Grinding Process Reduces Heat Treatment Distortion Dangers, Automotive Industries, vol. 46, no. 22, June 1, 1922, pp. 1162–1164, 3 figs. Finishing grinding gear teeth after heat treatment big factor in eliminating noise; permits resurfacing gears already finished cut to size and surfacing of gears which have grinding stock.

The Grinding of Gear Teeth and Its Future in the Industry, R. S. Drummond. Am. Mach. vol. 56, no. 21, May 25, 1922, pp. 779–781. Application of ground gear teeth in automotive industry; overcoming effects of heat treatment; elimination of noisy gearing by grinding. Paper read before Am. Gear Mfrs. Assn.

Testing, Optical. Testing Gear and Gear-Cutter Teeth, R. E. Flanders. Machy. (N. Y.), vol. 28, no. 10, June 1922, pp. 817–819, 6 figs. Description of screw-thread comparator for quickly detecting imperfections. (Abstract.) Paper read before Am. Gear Mfrs. Assn. convention.

[See also REDUCTION GEARS.]

GRINDING

Automotive Engine Parts. Grinds Automotive Engine Parts, N. H. Westervelt. Abrasive Industry, vol. 3, no. 4, April 1922, pp. 99–103, 6 figs. Grinding machines are employed extensively for finishing cylindrical and plane surfaces accurately; careful inspection is necessary.

H

HANDLING MATERIALS

German Mechanical Devices. Development of Mechanical Handling Devices in Germany During and Since the War, George Frederick Zimmer. Eng. & Indus. Management, vol. 7, no. 11, Apr. 6, 1922, pp. 334–340, 13 figs. Deals with mechanical handling devices for blast furnaces.

Port Development, and. Material Handling in Its Relationship to Port Development. Engrs. & Eng., vol. 1, no. 3, Mar. 1922, pp. 65–77 and 96. Symposium of following articles: Design of a Port to Take Full Advantage of Mechanical Equipment, by Carroll R. Thompson; What Has Been Done and What We Should Plan to Do, by Fred Jasperson; What Can Be Done with Ship's Gear, S. C. Loveland. Discussion.

[See also ASH HANDLING, COAL HANDLING.]

HEAT

Conservation. Thermotechnical Control of Works (Wärmetechnische Überwachung der Betriebe), H. Strache. Elektrotechnik u. Maschinenbau, vol. 40, nos. 16 and 17, Apr. 16 and 23, 1922, pp. 184–187 and 198–201, 5 figs. Apr. 16: Discusses means for better utilization of fuels, including heat balance and efficiency of boilers, flue gases, CO_2 determination, etc. Apr. 23: Discusses various instruments for analyzing flue gases, draft gages, temperature measurement, selection of coal.

HEATING AND VENTILATING

Individual Units. Individual Heating and Ventilating Units, James Mackay. Domestic Eng. (Chicago), vol. 99, nos. 5 and 6, Apr. 29 and May 6, 1922, pp. 189–191 and 231–232, 11 figs. Notes on construction, installation and operation.

Research. Rietschel's Work and Its Continuation (Das Werk Rietschels und seine Fortführung), K. Brabbée. Gesundheits-Ingenieur, vol. 45, no. 16, Apr. 22, 1922, pp. 205–215, 25 figs. Reviews experimental work in heating and ventilating which was carried out by Rietschel and gives examples of results obtained.

HEATING, ELECTRIC

Industrial. Industrial Electric Heating for Factories, Wirt S. Scott. Elec. Jl., vol. 19, no. 5, May 1922, pp. 203–208, 8 figs. Pointing out the many possibilities as yet partially or entirely undeveloped.

HEATING, STEAM

Central Stations. Commission for the Utilization of Fuel—4th Report (Commission d'Utilisation du Combustible). Annales des Mines, vol. 1, no. 3, Mar. 1922, pp. 192–256. Gives report of First Sub-committee on actual practice at central steam heating stations, discussing their general character, types of boilers, superheating, economizers, air preheating, feedwater, etc.

HELICOPTERS

See AIRCRAFT, Power Requirements of.

HELIUM

Production. The Industrial Production of Helium, S. G. Roberts. Sci. Am., vol. 126, no. 5, May 1922, pp. 308–309, 5 figs. Improvements in past five years toward development of non-explosive airship.

HYDRAULIC MACHINERY

Rams. Hydraulic Rams, E. W. Anderson. Instn. Mech. Engrs. Proc., no. 2, 1922, pp. 337–355, 3 figs. Description of Anderson ram developed from experiments by author.

HYDRAULIC TURBINES

High-Speed Runners. Developments in High-Speed Runners for Hydraulic Turbines, Frank H. Rogers. Power, vol. 55, no. 17, Apr. 25, 1922, pp. 640–643, 8 figs. Limitations of Francis-type runners; comparison of different types of high-speed propeller runners; location of turbine with respect to tailwater; use of inverted-type and ejector-type turbines in low-head plants.

Mixed-Flow. The American Mixed-Flow Turbine and Its Setting, Arthur T. Safford and Edward Pierce Hamilton. Am. Soc. Civil Engrs. Proc., vol. 48, no. 4, Apr. 1922, pp. 753–808, 34 figs. Review of developments of turbine runner and of water-wheel setting.

Surge Tanks. Surge Tanks, B. F. Jakobsen. Am. Soc. Civil Engrs. Proc., vol. 48, no. 4, Apr. 1922, pp. 853–869, 15 figs. Distinction between surge-tank acceleration and deceleration and difference in requirements for medium-high head and high-head plants.

HYDROELECTRIC DEVELOPMENTS

Colorado River. Tentative Plan for the Construction of a 780-Foot Rock-Fill Dam, on the Colorado River, at Lee Ferry, Arizona, E. C. LaRue. Am. Soc. Civil Engrs. Proc., vol. 48, no. 4, Apr. 1922, pp. 835–852, 7 figs. Discusses practicability of constructing rock-fill dam in Colorado River; designed to raise water 700 ft. above river bed.

Colorado River Project. The World's Greatest Electrical Project, C. H. Peirson. Universal Engr., vol. 35, no. 5, May 1922, pp. 29–31. Plan to develop two and one-half million hp. of electric energy for power purposes.

HYDROELECTRIC PLANTS

Auxiliaries, Selection of. Selection of Auxiliaries for Hydro-Electric Power Stations, F. H. Rogers. Power, vol. 55, no. 20, May 16, 1922, pp. 775–777, 4 figs. Pumping statements for governor fluid. Lubrication statements for bearings. Small water wheels for auxiliary power.

Developments. Hydro-Electric Developments Involve an Expenditure of $150,000,000. Elec. World, vol. 79, no. 19, May 13, 1922, pp. 951–953, 2 figs. Construction in progress under licenses granted by Federal Power Commission involves almost 1,750,000 hp. Big Creek project largest for which license has been granted.

Kern River, California. Hydroelectric Installation on the Kern River, Ely C. Hutchinson. Universal Engr., vol. 35, no. 5, May 1922, pp. 23–26, 7 figs. Two turbo-generators arranged for dual operation at either 50 or 60 cycles; unique equipment for efficient use of water supply. (Abstract.) Paper presented at meeting of San Francisco Section of A.S.M.E.

New Brunswick. New Hydro Plant in New Brunswick. Contract Rec., vol. 63, no. 20, May 17, 1922, pp. 474–477, 5 figs. Unique installation just completed at Musquash River near St. John. Actually 2 plants in one. Work of New Brunswick Power Commission.

Smoky Falls, Ont. Smoky Falls Development on the Sturgeon River, C. C. Irvine. Can. Engr., vol. 42, no. 15, Apr. 11, 1922, pp. 377–379, 4 figs. Details of hydroelectric plant for Spanish River Pulp and Paper Mills at Smoky Falls, Ont. Present installation of 5200 hp. in two units with provision for two more units. Details of turbines and generators.

Western, Special Problems. Western Hydroelectric Development Meets Special Problems. Jl. Elec. West. Industry, vol. 48, no. 10, May 15, 1922, pp. 400–402. Western practice in meeting special conditions of water-power development on this coast analyzed in comprehensive report of hydraulic power committee of Pacific Coast electrical association.

I

IMPACT TESTING

Methods. A Discussion of Impact Testing Methods and the Results Obtained, John M. Lessells. Am. Soc. for Steel Treating Trans., vol. 2, no. 8, May 1922, pp. 659–672, 22 figs. Value of this method which shows up characteristics in heat-treated steel and not evident from conventional tests.

INDUSTRIAL MANAGEMENT

Bosses. Management that Includes Bosses in the Office and in the Shop, Frank E. Gooding. Elec. Rev. & Indus. Engr., vol. 80, no. 5, May 1922, pp. 260–261. Influence of industrial engineering on earnings of capital and labor. Conservation of materials, plant and equipment, and labor. Discussion at meeting of Soc. Indus. Eng.

British Factory. Scientific Management in the British Factory, Wm. J. Hiscox. Am. Mach., vol 56, no. 23, June 8, 1922, pp. 837–838. Considered by some a revolutionary movement; why it cannot be adopted as a whole; methods not popular with organized labor.

Cost Recording and Production Control. Cost Recording and Production Control in Drop-Forging Plants, H F Ouler. Machy (N Y) vol 29 no 10, June 1922, pp. 807-809, 3 figs. Description of system of management which has proven very successful in two drop-forging plants.

Divergence Charts. Divergence Charts and Their Uses, G. W. Greenwood. Management Eng., vol 2, no. 6, June 1922, pp 347 350 4 figs. Means of presenting absolute differences between two magnitudes from month to month, and value of same.

File Factory, Organisation of. The Organisation of File Factories, H. G. Smith. Eng. & Indus. Management, vol. 7, no. 15, June 1, 1922, pp. 473-477. Development of organisation from point when manufacturer orders raw material. Lecture before Sheffield File Trades Technical Soc.

Foundry Control. Co-ordinating Foundry Control, D. M. Avey. Iron Trade Rev., vol 70, no 22, June 1, 1922, pp. 1563-1566, 7 figs. How five large castings manufacturing plants solved problem of executive control involved through combining direction of general shop practice and research under one directing head.

Inspection Methods. Inspection Methods, E. Fairbrother. Eng. Production vol 4, no 78, 79 and 80, Mar 30, Apr 6 and 13, 1922, pp. 303-306, 314-319 and 338 343, 33 figs. Development and practice. Notes on duties of an inspector, location of inspection department in factory. A system is described. Paper presented before Instn. Production Engrs.

Locomotive-Shop Schedules. Scheduling Operations in a Locomotive Repair Shop. Boiler Maker, vol. 22 no. 5, May 1922 pp 121 125 and 138, 8 figs. Planning and routing repair operations and material; checking work as completed according to department schedules, eliminating delays by means of foremen check sheets.

Manager's Problems. Solving the Manager's Present Day Problems, John H. Van Deventer. Indus. Management, vol. 63, no 6, June 1922, pp. 321 324. Fixity and flexibility as factors in organization.

Organization for Small Plant. A Workable Organization Plan for the Small-Plant Manager, M. B. Bartlett. Factory, vol 28, no. 6, June 1922, pp. 640-643, 662 and 664, 3 figs. Practical system covering cost and purchase records, routine adaptable to most small plants.

Personnel Department, Duties of. Duties of a Personnel Department in an Industrial Plant, Bruce F. Brown. Jl Elec. & West. Industry, vol. 48, no. 11, June 1, 1922, pp. 443-444. How one successful western industry has solved industrial problems among its workers by developing scope of its personnel department.

Production Planning. Planning with Equipment Standards, Chester D. Buoy. Indus. Management, vol. 63, no. 6, June 1922, pp. 363-365, 2 figs. Effective means of putting accurate and complete equipment standard data at service of planning department.

Production Regulation. Managing Production According to the Business Cycle, Ernest F. DuBrul. Management Eng., vol. 2, no. 6, June 1922, pp. 343-346, 1 fig. Fitting supply to demand in booms and depressions, analyzing business cycles.

Records, Equipment and Inspection. Equipment and Inspection Records. Elec. Rev. & Indus. Engr., vol. 80, no. 5, May 1922, pp. 211-213 and 216, 3 figs. Description of simple system which can be modified to suit large or small shop requirements.

Slow Sales. The Factory Cure for Slow Sales, E. L. Wayman. Factory, vol. 28, no. 6, June 1922, pp. 631-635, 2 figs. Investigation into production results in improvement in sales.

Stock Control. Flexible Stock Control at Lower Cost, H. J. Whitten. Factory, vol. 28, no. 5, May 1922, pp. 536-538 and 552, 3 figs. Notes on modern scientific store methods.

Works Organization. Works Organization—T. E. Pattinson. Eng. & Indus. Management, vol. 7, nos. 12, 13 and 14, Apr. 20, May 4 and 18, 1922, pp. 354-356, 388-391 and 430-431, 19 figs. Discusses ways of dealing with scrap and gives scrap charts. Machine-shop layout and operation. Paper read before Instn. Production Engrs.

INDUSTRIAL ORGANIZATION

Modern. Modern Industrial Organization, Hugo Hirst. Electrician, vol. 88, no. 2297, May 26, 1922, pp. 625-626. Some views gathered from 35 years' experience along this line. Based on address before Assn. Civil Servants.

INDUSTRIAL TRUCKS

Steam. Garrett Under-Type Steam Wagon. Engineer, vol. 133, no. 3458, Apr. 7, 1922, pp. 384-386, 13 figs. partly on supp. plate and p. 388. Features of interest of six-ton steam wagon are employment of pressed steel frame, double-chain drive, pedal speed regulator, and employment of Timken roller bearings.

INSULATION

Refrigerating Field. The Economic Thickness of Insulation in the Refrigerating Field, P. Nicholls. Am. Soc. Heating & Vent. Engrs. Jl., vol. 28, no. 3, Apr. 1922, pp. 343-358, 6 figs. Espense caused by leakage of heat, and formulas whcih include all definite expense factors. Consideration of case of walls of ice and cold-storage houses.

INTERNAL-COMBUSTION ENGINES

Hesselmans. A New Internal-Combustion Engine (En ny förbränningsmotor), E. Hubendick. Teknisk Tidskrift, vol. 52, no. 16, Apr. 22, 1922, pp. 259-266, 15 figs. Describes in detail the Hesselmans engine, its construction, and results of tests made with it.

[See also AIRPLANE ENGINES, AUTOMOBILE ENGINES, DIESEL ENGINES, OIL ENGINES, SEMI-DIESEL ENGINES.]

IRON

Spontaneous Ignition of Aluminum and. Spontaneous Ignition of Iron and Aluminum Chips (Die Selbstentzündung von Eisen- und Aluminiumspänen). Wärme- und Kälte-Technik, vol. 24, no. 8, Apr. 15, 1922, p. 97. Discusses the danger and recommends storage under water.

IRON INDUSTRY

Lorraine and Luxemburg. German Development of Iron Industries in Lorraine and Luxemburg to the End of 1918 (Stand des deutschen Ausbaues der lothringischen und luxemburgischen Eisenindustrie bis zum Jahre 1918), Walther Haug. Stahl u. Eisen, vol. 42, no. 19, May 11, 1922, pp. 728 734, 8 figs. Detailed description of development of blast-furnace works Karlshütte, Diedenhofen, and condition of works at end of 1918.

L

LADLES

Geared Design. Design Affects Ladle Operation, A. W. Gregg. Iron Trade Rev., vol 70, no. 23, June 8, 1922, pp. 1648-1650, 4 figs. Different types of gearing have direct relation to ease in handling and safety; merits and disadvantages of worm, spur and helical worm gears; care of equipment emphasized. From paper read before Am. Foundrymen's Assn.

LATHES

Automatic. Milling Eight Transmission Covers At One Time, J. H. Moore. Can. Machy., vol. 27, no. 18, May 4, 1922, pp. 33-35, 8 figs. Describes automatic lathe designed for rapid production of duplicate parts in large quantities.

Turret. Saving Money by Means of the Turret Lathe, H. Alton. Can. Machy., vol 27, no. 21, May 25, 1922, pp. 17-20, 10 figs. Production increased by efficient chucks and work-holding fixtures; indexing devices with ample wearing surface most suitable; machining hydraulic shock absorber; operations on bronze valve.

LIGHTHOUSES

Kerosene Lights. Developments in the Use of Paraffin for Coast Lighting. Engineering, vol. 113, no. 2940, May 5, 1922, pp. 541-544, 4 figs. Description of "Matthews," "Lux" and "Hood" burners; intensity of illumination and economy of each.

LIGHTING

Buildings. The Lighting of Public Buildings, A. L. Powell and Edgar Parker. Illuminating Eng. Soc. Trans., vol. 16, no. 9, Dec. 30, 1921, pp. 533-550, 13 figs. Lighting of art galleries, statuary, museums, libraries, municipal, county and state buildings, and banks. Bibliography.

Illumination Requirements for Workshops of Optical and Precision Instruments (Die lichttechnischen Anforderungen an die Beleuchtung von Optiker- und Feinmechaniker-Werkstätten) H. Lux. Deutsche Optische Wochenschrift, vol. 8, nos. 19 and 20, May 7 and 14, 1922, pp. 350-353 and 372-373, 1 fig. Discusses standards of German Illumination Soc. on general and local lighting, daylight and artificial lighting, etc.

Factory. Lighting the Factory, S. G. Hibben. Factory, vol. 28, no. 5, May 1922, pp. 523-526, 6 figs. Discusses harnessing daylight with refracting prisms, curtains and ground glass; and substituting for artificial light in whole or in part.

Industrial. Industrial Illumination. Eng. & Indus. Management, vol. 7, no. 14, May 18, 1922, pp. 450-451, 453, 455 and 457-460, 11 figs. Effect of good lighting on production; choice of lamps and fittings; correct light distribution; increasing workers' efficiency; economy in workshop.

Signs, Legibility. Factors that Determine Sign Legibility, C. A. Atherton. Elec. World, vol. 79, no. 21, May 27, 1922, pp. 1061-1064, 6 figs. Distance at which electrical announcements can be read may be diminished by brightness of lamps; atmospheric absorption compensates for brightness; mathematical relation of factors as determined by research.

Street. Highway Lighting, H. H. Ashinger. Elec. Jl., vol. 19, no. 5, May 1922, pp. 194-195, 2 figs. Design features of lighting units.

Improved Lighting System to Be Installed on Lincoln Highway, H. H. Bell. Elec. World, vol. 79, Apr. 15, 1922, pp. 731-732, 5 figs. Among features which it is intended shall mark completed work are concentration of light on roadway, flexibility of arrangement and reasonable cost of installation and maintenance.

The Value of Improved Street Lighting, C. H. Shepherd. Elec. Jl., vol. 19, no. 5, May 1922, pp. 187-190, 4 figs. Bringing out importance of proper street illumination and value to community

LIGNITE

Burning. Direct Drying of Brown Coal by Flue Gases and Firing the Dried Coal in Powder Form (Unmittelbare Trocknung der Rohbraunkohle mittels Feuergasen und Verheizung der getrockneten Kohle in Staubform), Max Weiss. Technische Blätter, vol. 12, No. 18, May 6, 1922, pp. 185-186, 3 figs. Describes installation of this kind in operation at Becker steel works at Willich.

LOCOMOTIVE BOILERS

Firebox Crown Stays. Stresses in the Firebox Crown Stays of Locomotive Boilers. Engineering, vol 113, no 2939, April 28, 1922, pp 514 515, 4 figs. Staybolts directly connected to shell plating of cylindrical form as means of eliminating secondary stresses. Formulas and tables showing stresses.

LOCOMOTIVES

British and American. British and American Locomotive Design and Practice, P. C. Dewhurst. Engineer, vol 133, no. 3456, Mar 24, 1922, pp. 335-336. Comparison of systems. See also Ry. Gaz., vol. 36, no. 14, Apr 7, 1922, pp. 593-596. (Abstract.) Paper read before Instn. Mech. Engrs.

British 4 6-2. 4 6 2 Type Passenger Locomotive for the Great Northern Railway. Engineering, vol. 113, no 2937, Apr. 14, 1922, pp. 454-456, 6 figs. Engine has three cylinders, 20 in. by 26 in., and coupled wheels 80 in. in diam.; grate area, 41 25 sq. ft., coupled with firebox heating surface, 215 sq. ft. Boiler is of conical type, with front-ring barrel diam. of 69 in.

Construction. Locomotive Construction. Eng. Production, vol. 4, nos 79 and 80, Apr. 6 and 13, 1922, pp. 321-327 and 347-351, 28 figs. Methods in Great Western Works at Swindon, England.

Design and Practice. British and American Locomotive Design and Practice, P. C. Dewhurst. Ry. Engr., vol 43, no. 508, May 1922, pp. 169-172. Summary of paper read at recent meeting of Inst. of Mech. Engrs.

Decapod. Russian "Decapod" Locomotives, A. Lipetz. Ry. Engr., vol. 43, nos. 505 and 507, Feb. and Apr. 1922, pp. 51-54 and 136-137, 9 figs. Describes new 2-10-0 type locomotive built in America to conform with Russian Ministry of Railways specification.

4-Cylinder Compound Rack Type. Four-Cylinder Compound Rack Type Locomotives (Cl+Z) at the Höllental Railroad in Baden (Die Vierzylinderverbund-Reibungs- und -Zahnradlokomotiven (Cl+Z) auf der badischen Höllentalbahn). Zeit. des Vereines deutscher Ingenieure, vol. 66, no. 15, Apr. 15, 1922, pp. 361-366, 13 figs. Design; construction; equipment; performance; operation.

Power Transmission in. Power Transmission in Locomotives From the Engine to the Wheels (Di alcuni dei principali biellismi per trasmissione del movimento dai motori alle ruote nelle locomotive a motori rotanti), Andrea Caminati. Elettrotecnica, vol. 9, no. 10, Apr. 5, 1922, pp. 222-230, 19 figs. Principles of individual transmission, and for various combinations of wheels.

Tests. Results of Tests With Steam Locomotives (Versuchsergebnisse mit Dampflokomotiven), R. Sanzin. Forschungsarbeiten auf dem Gebiete des Ingenieurwesens, no. 251, 1921, 37 pp., 28 figs. Describes tests carried out with special runs to determine maximum tractive power and gives particulars as to fuel, evaporation, etc.

Turbine, Application of. Application of the Turbine to Locomotive Practice. Can. Ry. & Mar. World, no. 292, June 1922, pp. 280-281. Various recent experiments in application of turbines to locomotives.

Turbine Type. Turbine Locomotive Saves 52 Per Cent in Fuel. Ry. Age, vol. 72, no. 22, June 3, 1922, pp. 1295-1296, 1 fig. Describes many novel features of design brought out by Ljungstrom Turbine Co. of Sweden.

Uniflow, Developments. Recent Developments in the Unaflow Locomotive. Ry. Mech. Engr., vol. 96, no. 5, May 1922, pp. 247-250, 7 figs. Exhaust ejector effect overcomes handicap of high compression and reduces size of cylinders.

LUBRICATING OILS

Viscosity. Influence of Viscosity on Operation of Oiling Systems, W. F. Osborne. Power, vol. 55, no. 21, May 23, 1922, pp. 820-821. Mechanical considerations where oil is to be used; effect of viscosity.

LUBRICATION

Filtering Methods. Modern Filtering Methods for Lubricating Systems, W. F. Osborne. Power, vol. 55, no. 24, June 13, 1922, pp. 930-931, 3 figs. Advantages and disadvantages of five general methods.

M

MACHINE TOOLS

Attachments. Attachments for Surfacing, Boring, and Drilling Machines. Engineer, vol. 133, no. 3458, Apr. 7, 1922, p. 395, 5 figs. Describes series of attachments now being made by H. W. Kearns & Co., Ltd., Broadheath, including vertical milling, flange-drilling and grinding attachments and dial traverse indicators.

Automatic. Automatic Machines Replace Hand Labor. Iron Age, vol. 109, no. 16, Apr. 20, 1922, pp. 1057-1060, 8 figs. Element of human error eliminated and production costs reduced with special equipment at plant of Bock Bearing Co., Toledo.

Design. Methods of Machine Tool Design, A. L. DeLeeuw. Am. Mach., vol. 56, nos. 16 and 17, Apr. 20 and 27, 1922, pp. 577-579 and 617-620, 3 figs. Points out that usual machine-design methods do not always apply in designing machine tools. Apr. 20: Definition, classification and requirements of a machine tool. Apr. 27: Design of commercial and single-purpose machines contrasted. Shorthand symbols for designer.

Tool Engineering, Albert A. Dowd and Frank W. Curtis. Am. Mach. vol. 56, no. 19, May 11, 1922, pp. 702-705, 6 figs. Methods employed in designing tools for turret lathes. Use of layouts and

sketches, familiarity with machines necessary for designer.

Design Standards. Tool Design Standards, H. P. Losely. Machy. (N. Y.), vol. 28, no. 9, May, 1922, pp. 713–715, 2 figs. Development of standard instruction sheets for use of tool designers.

Railway Shops. Machine Tools in the Railway Shop. Eng. Production, vol. 4, nos. 76, 77, 78, 79, 80, 81, 82 and 83, Mar. 16, 23, 30, Apr. 6, 13, 20, 27 and May 4, 1922, pp. 244–248, 279–283, 293–297, 329–332, 352–357, 366–370, 398–403 and 427–432, 106 figs. Review of latest practice in machine-tool and other equipment designed for use in railway shops. Describes representative types of modern equipment.

MACHINE WORK

Optical Instruments, Use in. Use of Optical Instruments in Machine Work. Am. Mach., vol. 56, no. 19, May 11, 1922, pp. 697–701, 19 figs. Microscope and projector used to check location and contour of work. Accurate gear and rack cutting; an eyepiece with radial lines.

MAGNESIUM

Use in Foundry. Magnesium and Its Use in the Foundry (Le Magnésium et son utilisation en Fonderie), J. Gaillard. Fonderie Moderne, no. 1, Jan. 1922, pp. 17–21. Substitution of aluminum by magnesium, and chemical properties of latter; magnesium alloys; etc.

MAGNESIUM ALLOYS

Dowmetal. Dowmetal and Its Applications, J. A. Gann. Am. Soc. for Steel Treating Trans., vol. 2, no. 7, Apr. 1922, pp. 607–615 and (discussion) 615–619, 14 figs. Describes series of magnesium alloys produced by the Dow Chemical Co., commercially known as dowmetal. Characteristics and uses.

MARINE BOILERS

Economic Equipment and Operation. Possibilities of Further Economy in Marine Boilers, John Reid. Engineering, vol. 113, no. 2937, Apr. 14, 1922, pp. 472–475, 8 figs. Author suggests certain remedies for heat losses in Scotch boilers and indicates how they may be applied. Paper read before (British) Instn. Nav. Architects.

MATERIALS

Pressure Effect on Physical Properties. Change of the Physical Properties of Materials with Pressure, Erskine D. Williamson. Franklin Inst. Jl., vol. 193, no. 4, Apr. 1922, pp. 491–513, 8 figs. Tools employed in experiments. Change of electrical resistance with pressure; effect of pressure on thermoelectromotive force at junction of two metals; conductivity of solutions; effect of pressure on compressibility; and on viscosity of liquids.

MEASUREMENTS

Flattening of Measuring Bodies. The Validity of the Hertzian Formulas for the Calculation of the Flattening of Measuring Bodies (Ueber die Gültigkeit der Hertzschen Formeln zur Berechnung der Abplattung von Messkörpern), G. Berndt. Zeit. fur technische Physik, vol. 3, nos. 1 and 3, 1922, pp. 14–21 and 69–78, 2 figs. Investigation of validity of Hertz's formulas for calculation of deformation of unlevel surfaces of measuring bodies.

MEASURING INSTRUMENTS

Selection and Use. The Selection and Use of Instruments in Industrial Plants, Frederick J. Schlink. Management Eng., vol. 2, no. 6, June 1922, pp. 337–342, 6 figs. Importance of care in selection and use, and suggestions.

METALS

Kinetic Theory and Thermal Energy. On the Kinetic Theory of Solids (Metals) and the Partition of Thermal Energy, B. M. Sen. Lond., Edinburgh, & Dublin Philosophical Mag., vol. 43, no. 256, Apr. 1922, pp. 672–687, 1 fig. Part I: Investigation of theory of solid state with rough working model of 14 molecules placed on sphere about each individual molecule at center. Part II: Restatement of theory for cubic and face-centered cubic crystals.

Mechanical Properties. On the Variation of Mechanical Properties of Some Metals and Alloys at Low Temperatures (Sur la variation des propriétés mécaniques de quelques métaux et alliages aux basses températures), Léon Guillet and Jean Cournot. Révue de Métallurgie, vol. 19, no. 4, Apr. 1922, pp. 215–221, 9 figs. Describes experiments with special steels, ferronickel, cobalt, copper alloys, and aluminum alloys, and gives results in tabular form.

MICA

Properties and Uses. Properties and Uses of Micas. Instn. Elec. Engrs. Jl., vol. 60, no. 307, Mar. 1922, pp. 339–342 and (discussion) 342–346. Notes on specifications, identification tests; selection mica and micanite for commutators; commutator segment separators; rings and cones. Report from British Elec. & Allied Industries Research Assn. See also India-Rubber Jl., vol. 63, no. 19, May 13, 1922, p. 16.

MONEL METAL

Arc-Welding, Metallic Deoxidizers. The Use of Metallic Deoxidizers in Arc-Welding with Monel Metal, P. D. Merica and J. G. Schoener. Am. Welding Soc. Jl., vol. 1, no. 5, May 1922, pp. 13–18, 6 figs. New method which has overcome difficulties of welding this metal. Welding properties of monel metal; preparation and composition of coating powder; some tests of arc welding.

MOTOR BOATS

French Navy, Coastal. Coastal Motor Boat for the French Navy. Engineering, vol. 113, no. 2940, May 5, 1922, pp. 548–551, 15 figs. Description of small high-speed torpedo vessels which are adopted as result of usefulness during war.

MOTOR BUSES

Garford and Fageol. New Designs Added to Growing List of Special Bus Chassis. Automotive Industries, vol. 46, no. 19, May 11, 1922, pp. 1003–1005, 4 figs. Underslung springs and worm permit use of lower body platforms, while kickup in frame gives necessary axle clearance. Wider tread gives more body space and greater stability. Unit powerplant used in Fageol stage.

Paris. A New Parisian Omnibus (Un nouvel Omnibus parisien), Jean Texier. Industrie des Tramways, vol. 16, no. 182, Feb. 1922, pp. 37–41, 6 figs. Details of construction of a three-axle motor bus having 48 seats with front and back wheels driven.

MOTOR TRUCKS

Construction, German. The Present Status of German Motor Truck Construction (Der Stand des deutschen Lastkraftwagenbaues), Erwin Aders. Zeit. des Vereines deutscher Ingenieure, vol. 66, nos. 16 and 17, Apr. 22 and May 6, 1922, pp. 387–391 and 443–447, 31 figs. Apr. 22: Discusses increased employment of motor trucks; improvements in construction, especially of engines, lubrication, atomizers, cooling, etc. May 6. Driving, braking, spring suspensions, etc.

Design. Motor Truck Design from the Truck Buyer's Viewpoint, Cornelius R. Myers. Indus. Management, vol. 63, no. 5, May 1922, pp. 273–281, 11 figs. Important features in buying transportation which might be overlooked in salesman's emphasis on detail.

Logging Methods. Motor Truck Logging Methods, Frederick Malcolm Knapp. Univ. of Wash. Eng. Exper. Station Bul., no. 12, Apr. 1921, pp. 3–29, 13 figs. Useful facts for ordinary truck type not including tractor and caterpillar.

Motors. Thermic Importance of Motors for Trucks (Thermische Vervollkommnung der Kraftwagen-Motoren), Heller. Archiv fur Warmewirtschaft, vol. 3, no. 4, Apr. 1922, pp. 67–70, 17 figs. Method of packing; limitation of heat transmission to walls; experiments with pistons of various alloys; play and wear of pistons; etc.

Producer-Gas-Fueled. Land Transport and the Gas Producer, R. J. Mitchell. Eng. Rev., vol. 35, no. 10, Apr. 1922, pp. 335–337, 1 fig. Description of gas producer developed by D. J. Smith applied to motor truck which shows marked economy over liquid-fueled type.

Straker-Squire. The 5-ton Straker-Squire Chassis, Automobile Engr., vol. 12, no. 163, May 1922, pp. 130–138, 18 figs. One of few entirely new British designs since war which abounds in original features; 58 hp. at 1100 r.p.m.

MOTORSHIPS

Diesel Machinery for Single-Screw. Diesel Machinery for Single-Screw Motor Ships, James Richardson. Engineering, vol. 113, no. 2936, Apr. 7, 1922, pp. 416–419, 8 figs.; also Shipbldg. & Shipg. Rec., vol. 19, no. 15, Apr. 13, 1922, pp. 471–475, 8 figs. Deals with problems inherent to single-screw Diesel machinery. Paper read before (British) Instn. Nav. Architects.

N

NON-FERROUS METALS

Gas Absorption and Oxidation. Gas Absorption and Oxidation of Non-ferrous Metals, B. Wyoski and J. W. Boeck. Trans. Amer. Inst. Min. & Met. Engrs., issued with Min. & Metallurgy, May 1922, no. 1160-N, 8 pp., 2 figs. Argument that oxidation and gassing of bronzes and red brasses can not take place simultaneously, and conditions effecting each.

O

OIL

Crude. Properties of Some Typical American Crude Oils. Oil Eng. & Finance, vol. 1, no. 19, May 29, 1922, pp. 613–616. Selected analyses from 33 Western oils and 39 from Eastern fields, carried out under auspices of U. S. Bur. Mines.

OIL ENGINES

Airless-Injection. New Airless-Injection System for Oil Engines, E. Lundgren. Motorship, vol. 7, no. 6, June 1922, pp. 444–445, 4 figs. Remarkable results obtained from highly scientific experiments made by Hesselman in Sweden.

Design and Operation. Oil Engine Hints. Power Plant Eng., vol. 26, no. 11, June 1, 1922, pp. 565–569, 5 figs. Proportions, installation of engine, operating suggestions for modern installation.

Foundations. An Erector's Experiences in Building Oil-Engine Foundations, L. H. Morrison. Power, vol. 55, no. 17, Apr. 25, 1922, pp. 651–654, 8 figs. Increasing use of this type of engine makes consideration of details of foundation design important.

OIL FUEL

Heavy Oils. Receiving Heavy Fuel Oils (Réception des combustibles liquides lourds). Bul. Technique du Bureau Veritas, vol. 3, nos. 11 and 12, Nov. and Dec. 1921 and vol. 4, no. 1, Jan. 1922, pp. 272–276, 293–295 and 8–13, 16 figs. Nov.: Calorific power and determination of quantity of sulphur. Dec.: Sampling on board ship with or without convenience of a laboratory. Jan.: Sampling of tanks, tank steamers, etc., and calculation of quantities taken aboard.

Receiving Heavy Liquid Fuels, Fuel Oils and Gas Oils (Reception des combustibles liquides lourds). Bul. Technique du Bureau Veritas, vol. 3, nos. 11 and 12, Nov. and Dec. 1921, pp. 272–276 and 293–295, 9 figs. Nov.: Distillation of oils, and experience with various apparatus. Dec. Testing on board ship with and without apparatus:

OPEN-HEARTH FURNACES

Design. Design of Open-Hearth Furnaces, A. D. Williams. Iron Age, vol. 109, no. 16, Apr. 20, 1922, pp. 1075–1076. Consideration of port areas and velocities as affected by pressures; chimney height determined.

Fuel Utilization. Utilizing Fuels in Open Hearths, Herbert F. Miller, Jr. Iron Trade Rev., vol. 70, no. 23, June 8, 1922, pp. 1646–1647 and 1650, 6 figs. Present pressures of both air and gas in gas-fired furnaces are too low and should be increased from ounces to pounds; experiments show that time of heating may be reduced. From paper read before Am. Iron & Steel Inst.

Valve Design. Improving Reversing Valve Design, Wm. C. Bulmer. Iron Trade Rev., vol. 70, no. 22, June 1, 1922, pp. 1560–1561 Types of air or gas valve providing most effective seal and affording unrestricted passage is considered best for open hearths; water-cooled slide with inclined seat is favored.

OSCILLOGRAPHS

Turbo-Generator Investigation. Investigation of Oscillation Phenomena in Turbo-Generators (Untersuchung von Schwingungserscheinungen an Turbo dynamos mit Hilfe des Vibrographen), Jos. Geiger. Zeit. des Vereines deutscher Ingenieure, vol. 66, no. 18, May 6, 1922, pp. 437–440, 39 figs. Explains investigation by means of vibrograph; methods of measuring used; successful methods adopted to eliminate vibration.

OXY-ACETYLENE CUTTING

Cutting Machines. Efficiency of Machine Cutting F. J. Maeurer. Welding Engr., vol. 7, no. 5, May 1922, pp. 17–23, 25 figs. Cutting with oxy-acetylene torch can be made to approach very closely maximum theoretical efficiency. Paper read before Am. Welding Soc.

Underwater. Cutting Metals Under Water. Robert G. Skerrett. Compressed Air Mag., vol. 27, no. 5, May 1922, pp. 129–133, 14 figs. Repairing broken 36-in. diam. water main under New York Harbor by means of submarine torch and compressed air.

OXY-ACETYLENE WELDING

Water Main, Submarine. The Repair of The New York-Brooklyn Submarine Water Main. Engineering, vol. 113, no. 2939, April 28, 1922, pp. 509–511, 8 figs. Account of procedure and discussion of apparatus used.

P

PAINTS

Photometric Integrating Spheres, for. Paints for Integrating Spheres, A. H. Taylor. Illuminating Eng. Soc. Trans., vol. 16, no. 9, Dec. 30, 1921, pp. 587–590 and (discussion) pp. 599–605. Requirements of satisfactory paint. Preparation of zinc-oxide paint now being used at Bur. of Standards.

PAPER MANUFACTURE

Power. Power Used in Papermaking, A. G. Darling and H. W. Rogers. Paper, vol. 30, no. 7, Apr. 19, 1922, pp. 20–24. Heat and mechanical energy must be balanced. Demands for steam in processes.

Water Wheels. Water wheels in Making Groundwood, Adolph F. Meyer. Paper, vol. 30, no. 7, Apr. 19, 1922, pp. 58–66. Suggestions as to selection and regulation of speed of water wheels for grinding machinery. Paper read before Tech. Assn. of Pulp & Paper Industry.

PAPER MILLS

Electric Generation of Steam. Electric Generation of Steam, Horace Drever and Frank Hodson. Paper, vol. 30, no. 7, Apr. 19, 1922, pp. 73–75 and 78–81, 3 figs. Recent development in conversion of electric energy into steam by means of electric steam generator; underlying theories and practical application. Paper read before Technical Assn. of Pulp and Paper Industry.

Electricity in, Use of. Electricity in the Paper Mill, R. W. Leeper. Paper, vol. 30, no. 7, Apr. 19, 1922, pp. 24–28. Uses of the force from power plant to finished product.

Water-Power Sources, Canada. Mill Waterpower Sources in Canada. Paper, vol. 30, no. 7, Apr. 19, 1922, pp. 11–18, 8 figs. Paper prepared by Dominion Water Power Branch of Dept. of Interior, Ottawa, Ont., giving power supply of various mills in Canada.

PATENTS

Ownership, Employer and Employee. Relation of Employer and Employee as Regards Ownership of Patents, Maurice Block. Chem. Age (N. Y.), vol. 30, no. 5, May 1922, pp. 201–202. Discussion of rights of employer and employee in patents on inventions developed by an employee. Legal precedents.

PETROLEUM

Bibliography. Recent Articles on Petroleum and Allied Substances. U. S. Bur. of Mines Reports on Investigations, serial no. 2340, Mar. 1922, 20 pp. Bibliography compiled by E. H. Boroughs.

Federal Specification Revision. Federal Government Revises Petroleum Specifications. Automotive Industries, vol. 46, no. 19, May 11, 1922, pp. 1012-1013, 1 fig. Color test only change of importance in respect to motor gasoline. Points on distillation curve unchanged. Viscosity limits on lubricating oils are altered and some minor changes are made in other items.

PHOSPHOR BRONZE

Properties and Manufacture. Phosphor-Bronze from the Engineering Standpoint, R. T. Rolfe. Metal Industry, vol. 20, nos. 18 and 19, May 5 and 12, 1922, pp. 413-416 and 437-438, 3 figs. May 5: Classification, composition and tests. Manufacture, microstructure and bearing properties of 85-15. May 12: Alloys for gear wheels and characteristics. Manufacture and uses of malleable.

PHOTOELASTICITY

Application to Engineering Problems. Photo-Elasticity and Its Application to Engineering Problems, P. Heymans. Tech. Eng. News, vol. 3, no. 3, June 1922, pp. 80-85, 96 and 100, 27 figs. Application of temporary birefraction properties, shown by transparent bodies when stressed, on general stress determinations.

PIGMENTS

Titanium. Manufacture and Properties of Titanium White (Fabrication et propriétés du blanc de titane), Ch. Coffignier. Chimie & Industrie, vol. 7, no. 4, Apr. 1922, pp. 651-661, 11 figs. Manufacture and properties of white pigments in Norway, America and France; describes Devaux, Paquet and Andreu processes.

PIPE LINES

Capacity-Calculation Chart. A Linear Chart for Calculating Pipe Line Capacities, C. H. M. Burnham. Natural Gas Industry, vol. 16, no. 5, May 1922, p. 163. Graphic method of solving usual pipe line capacity equation.

Superheated Steam. The Most Economic Pipe Diameter for Superheated Steam Lines (Der billigste Rohrdurchmesser für Heissdampf-Kraftleitungen), O. Denecke. Wärme, vol. 45, nos. 8, 9, 10 and 11, Feb. 24, Mar. 3, 10 and 17, 1922, pp. 104-105, 113-115, 125-128 and 136-139, 3 figs. Mathematical paper discussing pipe diameter for least steam loss on saturated-steam lines; most economic diameter for various loads of machines; increase of yearly operating costs by departing from most economic diameter, examples of practical calculations.

PIPES

Economic Size. Economic Size of Pipe for Power Purposes, George E. Lyon. Eng. & Contracting, vol. 57, no. 19, May 10, 1922, pp. 436-437, 1 fig. Formulas and curves from which proper diameters can be found.

PIPES, CAST-IRON

Flexible-Joint. Making 30-Inch Flexible Joint Cast-Iron Pipe, William G. Hammerstrom. Eng. News-Rec., vol. 88, no. 19, May 11, 1922, pp. 780-782, 5 figs. Spherical-shaped bell and spigot on each length machined to give flexibility at every joint; foundry practice.

PISTONS

Dowmetal. A Superior Piston Material. Motor Boating, vol. 29, no. 6, June 1922, pp. 39 and 100, 2 figs. Dowmetal, an alloy composed of high percentage of magnesium and small amounts of other metals, manufactured by Dow Chem. Co., Midland, Mich., for pistons of internal-combustion engines, equal, if not superior, to cast iron or aluminum.

Machining. Tooling Equipments for Pistons. Machy. (Lond.), vol. 20, no. 504, May 25, 1922, pp. 220-224, 13 figs. Use of automatic machines and special equipment for machining pistons at high rate of production.

POWER GENERATION

Rating of Supply Undertakings. The Rating of Electric Power Supply Undertakings, L. Andrews. Elec. Times, vol. 61, no. 1596, May 18, 1922, pp. 477-478, 1 fig. Economic consideration of various factors and necessity of analyzing same.

POWER PLANTS

Auxiliaries. Power Plant Auxiliaries, L. R. Lee. Power Plant Eng., vol. 26, no. 11, June 1, 1922, pp. 553-557, 4 figs. Requirements and types used in modern plants.

Auxiliaries Drive. Under What Conditions are Steam Turbines Preferable to Electrical Units for Driving Auxiliaries? Coal Age, vol. 21, no. 21, May 25, 1922, pp. 875-876, 1 fig. Turbines save conversion costs; independent steam units may release large generator at times of idleness; cheap fuel makes heat balance less imperative.

Calumet Station, Chicago. Calumet Station. Power Plant Eng., vol. 26, no. 10, May 15, 1922, pp. 497-508, 17 figs. Description of Commonwealth Edison Company's new plant which will ultimately produce 180,000 kw.

Hell Gate. New Hell Gate Power Station. Power, vol. 55, no. 18, May 2, 1922, pp. 678-686, 12 figs. Description and table of principal equipment of this plant of United Elec. Light & Power Co.

The Hell Gate Station, Howard W. Leitch. Elec. Jl., vol. 19, no. 5, May 1922, pp. 214-220, 14 figs. Layouts, curves, illustrations and general description.

Maintaining Heat Balance at Hell Gate. Power, vol. 55, no. 20, May 16, 1922, pp. 760-763, 4 figs. Features of units and control.

Switching Equipment for the Hell Gate Station, C. M. Moss and J. B. Macneill. Elec. Jl., vol. 19, no. 5, May 1922, pp. 221-226, 10 figs. Description of unusually good installation at this plant.

Lots Road Station, London. Lots Road Power Station, London "Underground" Railways. Ry. Gaz., vol. 36, no. 19, May 12, 1922, pp. 777-780, 3 figs. This station, opened in Feb. 1905, is largest in British Isles erected for supplying current for railway traction and associated purposes. New plant recently added is described, and main features of original equipment, in so far as it still applies, are set forth.

Producer-Gas. Some Observations on a Producer-Gas Power Plant, H. S. Denny and N. V. S. Knibbs. Instn. Mech. Engrs. Proc., no. 2, 1922, pp. 97-194, 17 figs. Thorough examination of use of coal with view to economy.

Sheboygan, Wis. New Plant of Badger State Tanning Co. Power Plant Eng., vol. 26, no. 11, June 1, 1922, pp. 547-553, 10 figs. Description of new installation of uniflow engines with a.c. individual motor drives.

POWER TRANSMISSION

Drive, Unit and Line. Comparative Advantages of Unit and Line Drive in Industry, H. P. Phillips. Jl. Elec. & West. Industry, vol. 48, no. 11, June 1, 1922, pp. 445-447, 6 figs. Discussion of mechanical installations in some important western industrial plants tending to show that adoption of unit or line drive depends upon type of work to be done.

Electric vs. Mechanical. The Merits of Electrical vs. Mechanical Power Transmission, R. Gillespie Williams. Eng. & Indus. Management, vol. 7, no. 11, Apr. 6, 1922, pp. 319-322, 3 figs. Deals with questions relating to running costs and maintenance, and economical arrangement of electric generator plant.

Fluid Waves. Transmitting Power in Fluid Waves. Sci. Am., vol. 126, no. 5, May 1922, pp. 320 and 362. Setting up wave motions or pulsations in enclosed column of liquid, usually water, which is contained in pipe connecting wave-generating apparatus with point of power application. Discusses generator now on market and applications.

Machinery. A Review of Power-Transmission Machinery. Belting, vol. 20, nos. 4 and 5, Apr. and May 1922, pp. 29-30 and pp. 36 and 38, 10 figs. Apr.: Deals with steel hangers. May: Steel pulleys and one type of steel hanger.

PRESSES

Accident Elimination. Eliminating Cold Trim Press Accidents, G. A. Kuechenmeister. Can. Machy., vol. 27, no. 21, May 25, 1922, pp. 21 and 29, 2 figs. Danger of working on unguarded presses; repeating of press ram not always cause of trouble; unsatisfactory experiments with mechanical tripping devices, electrical guard which has solved problem.

PULVERIZED COAL

Boiler Firing. Commission of Fuel Utilization—3rd Report (Commission d'Utilisation du Combustible). Annales des Mines, vol. 1, no. 2, Feb. 1922, pp. 99-152. Firing with pulverized coal. Actual developments in use of pulverized coal; description of installation using it; detailed description of advantages and drawbacks.

Firing With Pulverized Coal (Ueber Kohlenstaubfeuerungen), Max Birkner. Wärme, vol. 45, no. 16, Apr. 21, 1922, pp. 201-204, 3 figs. Storage of pulverized coal; pulverizing; economic limitation of size of powder; combustion chamber; some recent installations.

Powdered Coal, John Blizard. Colliery Guardian, vol. 123, nos. 3198, 3199 and 3201, Apr. 13, 21 and May 5, 1922, pp. 918-919, 990-991 and 1119-1120, 10 figs. Apr. 13: Functions of powdered-fuel plant; preparation and distribution of fuel. Apr. 21: Various appliances employed in use of pulverized fuel; applications of powdered fuel. May 5: Use of powdered fuel in raising of steam cost and inherent dangers involved. From Bul. Can. Dept. Mines.

Power Plants. First Large Plant Using Pulverized Coal Exclusively. Elec. World, vol. 79, no. 15, Apr. 15, 1922, pp. 720-724, 13 figs. partly on supp. plate. Lakeside generating station of Milwaukee Elec. Ry. & Light Co. designed for initial capacity of 40,000 kva., with ultimate rating of 200,000 kva. Central control and minimum of attendance. See also Power, vol. 55, no. 16, Apr. 18, 1922, pp. 604-610, 16 figs. partly on supp. plate; and Elec. Ry. Jl., vol. 59, no. 15, Apr. 15, 1922, pp. 633-640, 15 figs. partly on supp. plate.

PUMPING PLANTS

Hamilton, Ont. Beach Water Works Pumping Plant at Hamilton, R. De Bruno-Austin. Can. Engr., vol. 42, no. 19, May 9, 1922, pp. 462-468, 8 figs. General description of machinery, with special reference to recent installation of 2 ten-million-gallon pumping units; tests show efficiencies as high as 80 per cent; historical review of earlier equipment.

Maple Ridge, B. C. New Pumping Plant for the Maple Ridge Dyking in B. C., H. M. Burwell. Contract Rec., vol. 63, no. 20, May 17, 1922, pp. 465-467, 4 figs. Old pumps in service for 27 years for reclaiming 9,000 acres of rich land, replaced by two 20,000 g.p.m. electrically-driven centrifugal pumps. Unusual type of valves.

PUMPING STATIONS

Stand-By Service. A 2,500-Kva. Diesel-Engine Plant for Stand-by Service, Homer I. Steffa. Power, vol. 55, no. 21, May 23, 1922, pp. 804-809, 8 figs. Calumet station equipped with four 750-b.hp. two-stroke cycle Diesel-engine generator units, insuring breakdown service for sewage-pumping stations.

PYROMETERS

Optical. Disappearing Filament Pyrometer. Engineering, vol. 113, no. 2938, April 21, 1922, p. 501, 5 figs. Design and construction of optical pyrometer for industrial and laboratory work, made by H. Tinsley & Co.; improvement of this type of pyrometer by placing lamp in one arm of Wheatstone bridge.

R

RAILWAY ELECTRIFICATION

Austria. The Electrification of the Austrian Federal Railways and the Development of Austrian Water Power (Die Einführung der elektrischen Zugförderung auf den österreichischen Staatsbahnen und der Ausbau der österreichischen Wasserkräfte), R. Seifert. Zentralblatt der Bauverwaltung, vol. 42, nos. 21 and 22, Mar. 11 and 18, 1922, pp. 117-120 and 133-134, 4 figs. Discusses plans for electrification of 1788 km. of railway lines, of which 726 km. are double-track.

Chile. Electrification on the Chilean Railway. Ry. & Locomotive Eng., vol. 35, no. 5, May 1922, pp. 111-115, 6 figs. Solution of high cost of fuel, and congested traffic. Descriptions of locomotive equipment.

Gothard Line, Switzerland. Where Electrification Is Both Logical and Picturesque. Ry. Rev., vol. 70, no. 16, Apr. 22, 1922, pp. 559-564, 17 figs. Alpine water power being substituted for imported coal on famous Gothard line in Switzerland.

Industrial Plants. Yard Electrification of Industrial Plant Railways, D. M. Petty. Engrs. & Eng., vol. 1, no. 3, Mar. 1922, pp. 79-84 and 96-97. Underrunning third-rail scheme is best suited for heavy work and low voltages; existing substations used to supply d.c. power; etc.

Mountain Districts. Advantages of Electrical Operation in Mountain Districts, Frank Rusch. Gen. Elec. Rev., vol. 25, no. 6, June 1922, pp. 362-364. Some features of 660 route miles operation of C., M., & St. Paul Ry. Co., on five mountain ranges. (Reprinted from Milwaukee Employees Mag., Mar. 1922.)

Voltages Near Ground. Railway Electrification and Safety Limits of Voltages Near the Ground. Tramway & Ry. World, vol. 51, no. 24, May 18, 1922, pp. 243-244. Discussion of limits of voltage safety for third rail or near ground.

RAILWAY MANAGEMENT

Chinese Government. The Administration of Chinese Government Railways, Ching-Chun Wang. Assn. Chinese & Am. Engrs. Jl., vol. 3, no. 1, Jan. 1922, pp. 3-16, 2 figs. Development; statistical features; central administration; improvements.

RAILWAY MOTOR CARS

Diesel-Electric. Diesel-Electric Motor Cars for Railway Service. Ry. Age, vol. 72, no. 20, May 20, 1922, pp. 1183-1184, 2 figs. Successful operation in Sweden has led to introduction of 250-hp. cars.

Gasoline. Developments in Bus-Type Rail Cars for Local Service. Ry. Rev., vol. 70, no. 18, May 6, 1922, pp. 633-635, 5 figs. Describes rail cars with both Mack and White Company chassis.

Some Recent Developments in Gasoline Motor Rail Cars, W. L. Bean. Ry. Rev., vol. 70, no. 21, May 27, 1922, pp. 741-747, 8 figs. Present equipment admirable in design but limited in capacity; railways need larger cars built on same principle.

The Power Behind the Modern Gasoline Motor Rail Car. Ry. Rev., vol. 70, no. 19, May 13, 1922, pp. 669-673, 6 figs. Features to which consideration must be given in selection of power unit for gasoline rail-car operation. Describes Midwest heavy-duty high-speed engine.

Type Selection. Railcars are Needed—But What Type? Herbert Chase. Automotive Industries, vol. 46, no. 22, June 1, 1922, pp. 1150-1152, 6 figs. Consideration of factors entering into selection of type.

RAILWAY OPERATION

Amphibious. By Rail and By Water. Sci. Am., vol. 126, no. 6, June 1922, p. 374, 5 figs. Combination train and two barges invented by Belgian engineer for use in Congo.

Parallel Traffic Working. "Parallel" Traffic Working on South Eastern & Chatham Railway. Ry. Gaz., vol. 36, no. 20, May 19, 1922, pp. 805-814, 7 figs. By systematic scheduling of trains on "Parallel" basis in both directions, time-keeping is improved, facilities increased, signaling movements reduced, and engines and rolling-stock utilized to better advantage.

Suburban Passenger Service. The Operation of Heavy Suburban Passenger Services on A Steam Railway, F. V. Russell. Ry. Gaz., vol. 36, no. 21, May 26, 1922, pp. 841-842. Steam and electric traction compared. Suggestions for adoption by steam railways of features in use in electrically-operated ones. From Lecture before Roy. Soc. Arts.

Train Control. Automatic Train Control Systems. Ry. Elec. Engr., vol. 13, no. 4, Apr. 1922, pp. 117-126, 21 figs. Four articles, describing the Regan contact shoe and ramp type, the Simmen speed control system, the Wooding and the Miller systems.

Freight Train Tests of Train Control on the C. I. & W. R. R. Ry. Rev., vol. 70, no. 18, May 6, 1922, pp. 627-628, 1 fig. Particulars of test designed to show action of Shadle system of train control in operation of heavy freight train.

Shadle Automatic Train Signal-Stop. Ry. Elec. Engr., vol. 13, no. 5, May 1922, pp. 149–150, 3 figs. Intermittent ramp contact type incorporating cab signals and speed control which have been developed on C. I. & W.

The American Train Control System. Ry. Elec. Engr., vol. 13, no. 5, May 1922, pp. 156–159, 6 figs. Developed on Maryland and Pennsylvania railroad and brought before Interstate Commerce Commission in 1907. Installed on C. & O.; inspected by Railroad Administration in 1919. Intermittent contact type.

The Sprague System of Automatic Train Control. Ry. Rev., vol. 70, no. 21, May 27, 1922, pp. 747–757, 11 figs. Description of test installation in electric zone of New York Central R.R.

RAILWAY SHOPS

Management. Improvements in Workshop Management (Verbesserungen im Werkstättenbetrieb), Hans A. Martens. Verkehrstechnik, special number, May 1922, pp. 240–247, 1 fig. Discusses methods in use on German state railways and proposes improvements for more efficient control.

Tools and Fixtures. Special Tools and Fixtures in a Southern Railroad Shop, S. Ashton Hand. Am. Mach., vol. 56, no. 17, Apr. 27, 1922, pp. 613–616, 15 figs. Describes equipment of shops of Chesapeake & Ohio Ry., Richmond, Va.

RAILWAY SIGNALING

Alsace-Lorraine. Signaling on the Alsace-Lorraine Railways (Dispositions adoptées pour assurer la sécurité des trains sur le réseau d'Alsace-Lorraine), Georges Levi. Annales des Mines, vol. 1, no. 4, Apr. 1922, pp. 266–315, 10 figs. Describes in detail principles and operation of signaling system in force to assure safety of trains.

Interlocking. New Interlocking on the C. R. R. of N. J., Fred W. Bender. Ry. Signal Engr., vol. 15, no. 5, May 1922, pp. 184–189, 14 figs. Large electro-pneumatic plant at Phillipsburg, N. J., uses new operating mechanisms and lead-covered cables.

Location of Signals. Location of Signals as an Aid to Traffic Working, R. S. Proud. Engineering, vol. 113, no. 2939, April 28, 1922, pp. 533–535, 3 figs. Signals from standpoint of traffic handling rather than safety. Paper read before Instn. Ry. Signal Engrs.

RAILWAY TERMINALS

Electrification. Operation of an Electrified Terminal, L. E. Lynde. Elec. Traction, vol. 28, no. 5, May 1922, pp. 403–404, 2 figs. Conditions at Broad Street Station, Philadelphia, as compared with steam operation on this portion of Penna. system.

RAILWAY TIES

Electric Resistance. Electrical Resistance of Treated and Untreated Crossties, P. R. Hicks. Ry. Signal Engr., vol. 15, no. 5, May 1922, pp. 190–192, 2 figs. Results of measurements made by Forest Prod. Laboratory in coöperation with Chicago, Milwaukee & St. Paul.

RAILWAY TRACK

Machines for Track Work. Special Machines and Combinations for Track Work. Eng. & Contracting, vol. 57, no. 16, Apr. 19, 1922, pp. 368–370, 3 figs. Information on use of mechanical appliances and tools in track work and organization of labor involved, given in appendix to report presented before Am. Ry. Eng. Assn. by Committee on Rules and Organization. (Abstract.)

RAILWAYS

Australia and China. Railway Problems in Australia and China, T. R. Johnson. Inst. of Transport Jl., vol. 3, no. 4, May 1922, pp. 214–222 and (discussion) 222–225. Some facts about rail transportation in these two countries.

REDUCTION GEARS

Double. Double Reduction Gears in the SS. "Melmore Head," J. W. Wilkie. Engineering, vol. 113, no. 2937, Apr. 14, 1922, pp. 469–471, 6 figs. Detailed account of troubles experienced with double-reduction gearing, together with description of methods recently adopted to overcome them. [Paper read at Spring Mtg. of I. N. A.] See also Mar. Engr. & Naval Archt., vol. 45, no. 536, May 1922, p. 190 and Shipbldg. & Shipg. Rec., vol. 19, no. 15, Apr. 13, 1922, pp. 457–460.

Turbine. Turbine Reduction Gearing and Its Production, J. H. Melloy. Mar. Engr. & Naval Architect, vol. 45, no. 536, May 1922, pp. 184–187, 3 figs. Hobbing process with particular reference to Muir & Melloy patent hobbing machine. Abstract of paper read before Northwestern Branch of I.M.E.

REFRIGERANTS

Hydrocarbon. Some Properties of Hydro-Carbon Refrigerants, H. D. Edwards. A.S.R.E. Jl., vol. 8, no. 6, May 1922, pp. 488–495, 5 figs. Discusses use of butane, propane, ethane, and makes comparison with ammonia.

REFRIGERATING MACHINES

Compression. Effect of Water Cooling Jackets on Compression Refrigerating Machines (Der Einfluss des Kühlwassermantels an Kompressions Kältemaschinen), Walther Fischer. Forschungsarbeiten auf dem Gebiete des Ingenieurwesens, no. 244, 1921, 78 pp., 25 figs. Investigation into the advantage of water-cooling jacket on cylinder of compressor for refrigerating machines of various types.

REFRIGERATING PLANTS

Steam vs. Electric Drive. A Few Facts About Steam- and Electric-Driven Refrigerating Plants, G. E. Porce. Power, vol. 55, no. 22, May 30, 1922, pp. 855–856. Comparison of electric motors and other prime movers.

Testing Rules for. Rules for Efficiency Testing of Refrigerating Machines and Plants (Regeln für Leistungsversuche an Kältemaschinen und Kühlanlagen). Zeit. für die gesamte Kälte-Industrie, vol. 29, no. 4, Apr. 1922, pp. 57–68, 6 figs. Gives rules formulated by the German Refrigerating Soc. and also the Standard Committee of the German Industry.

REFRIGERATION

Insulation, Thickness of. The Economic Thickness of Insulation in the Refrigerating Field, P. Nicholls. Am. Soc. Heat. & Vent. Engrs. Jl., vol. 28, no. 3, Apr. 1922, pp. 343–358, 6 figs. Various items of monetary expense which leakage of heat causes and formulas which include all of the definite expense factors.

Low-Temperature. Recent Developments in Low-Temperature Work (Neuere Entwicklung der Tieftemperaturtechnik), F. Pollitzer. Zeit. für die gesamte Kälte-Industrie, vol. 28, no. 9, Sept. 1921, pp. 125–133, 12 figs. Discusses large increase in expenditure of energy to reach temperatures lower than that of liquid air; describes Borsigwalde oxygen works and their equipment.

RIVERS

Canalization of St. Lawrence. An Examination of the Plan for Canalizing the St. Lawrence River, Wilfred H. Schoff. Engrs. & Eng., vol. 1, no. 3, Mar. 1922, pp. 85–89. Author concludes that as economical investment in combined power and navigation it is not desirable. Better to develop each separately.

Colorado. Controlling the Principal Artery of the Southwest States, C. E. Grunsky. Jl. Elec. & West. Industry, vol. 48, no. 9, May 1, 1922, pp. 348–350, 4 figs. Discusses feasibility of construction of dam that would rise to height of 550 ft., storing 25,000,000 acre-ft. of water which will irrigate thousands of acres of arid land, protect Imperial Valley from disastrous floods and generate approximately 600,000 hp. of electrical energy.

The Colorado River; Its Control and Development. Eng. News-Rec., vol. 88, no. 18, May 4, 1922, pp. 741–744, 2 figs. Hydraulics of river and demand for power, flood control and irrigation subject of federal report. Recommendations include Boulder Canyon dam and all-American canal in Imperial Valley.

ROADS

Truck Overloading. Analysis of Connecticut's Traffic Census Data Yields Facts on Truck Overloading, J. Gordon McKay. Eng. News-Rec., vol. 88, no. 20, May 18, 1922, pp. 826–830, 5 figs. Digest of report made for U. S. Bur. of Public Roads shows every third truck to be loaded beyond capacity of truck and tires.

ROLLING MILLS

Cold-Rolling Strip. New Five-Stand Cold-Rolling Strip Mill. Iron Age, vol. 109, no. 19, May 11, 1922, pp. 1289–1291, 5 figs. Tandem mill of new design has unusual flexibility of control; electric power a feature.

Continuous. Development of Continuous Rolling Mills, John W. Sheperdson. Iron Age, vol. 109, nos. 11, 15 and 17, Mar. 23, Apr. 13 and 27, 1922, pp. 791–794, 993–995 and 1149–1151, 15 figs. Design affected by fundamental conditions, specific problems, and co-relation of units. Merchant mills not well adapted to continuous principle. Selection of cooling-bed length; staggering of mills. Paper read before Engrs'. Soc. West. Pa.

Electrification Progress. Mill Electrification Progresses, Wilfred Sykes. Iron Trade Rev., vol. 70, no. 22, June 1, 1922, pp. 1550–1554, 1 fig. Recent years have witnessed number of large installations of motor drives on rolling mills; operation results are satisfactory; power and motor size not limited; general plant layout discussed. From paper read before Am. Iron & Steel Inst.

Hot Billet Scraper. An Automatic Hot Billet Scraper, R. C. Rohrabacher. Iron Age, vol. 109, no. 17, Apr. 27, 1922, pp. 1126–1128, 6 figs. Mechanical device for removing defects in use in Canadian rolling mill. Advantages and savings.

Strip Mills. New Continuous Ten-Stand Strip Mill. Iron Age, vol. 109, no. 22, June 1, 1922, pp. 1510–1512, 3 figs. Compact unit which was designed for heavy production; interesting details given of electric drive; arrangement at Trumbull Steel Co.

Wrought-Iron Bars, Rolling. Power Required to Roll Wrought Iron Bars, Edwin L. Fletcher. Iron Age, vol. 109, no. 17, Apr. 27, 1922, p. 1144. Results of tests that were made in reducing 3-in. billets to $^1/_2$-in. rounds.

Zinc Sheet. Zinc Sheet Rolling Mills (Das Zinkblechwalzwerk), W. Krämer. Metall., no. 6, Mar. 25, 1922, pp. 67–71, 5 figs. Gives list of mills supplying zinc. Describes operations of the various passes which are similar to that of iron sheets.

ROPE

Flexible Steel. Making and Care of Flexible Steel Ropes, W. Voigtlander. Iron Age, vol. 109, no. 16, Apr. 20, 1922, pp. 1065–1066, 1 fig. Operation of stranding machines; securing open ends of rope; effective strength with some wires broken.

Making and Care of Flexible Steel Ropes, W. Voigtlander. Eng. & Indus. Management, vol. 7, no. 15, June 1, 1922, pp. 463–465. Description of three steps in manufacture, lubrication and inspection when in use. Based on paper read before Assn. Iron & Steel Elec. Engrs.

S

SAFETY

Electricity in Factories. Electricity and Safety First in Factories, W. H. Seal. Electrician, vol. 88, no. 2297, May 26, 1922, pp. 618–623, 4 figs. Suggests code of safety rules; precautions desirable in using electrical machinery.

SAWS

Wire, for Slate and Marble. Wire Saws for Slate and Marble Cutting. Quarry, vol. 27, no. 303, May 1922, pp. 181–183, 4 figs. Description of this kind of saw used in England and abroad.

SCRAP

Railroad, Reclaiming of. Reclaiming a Railroad Scrap Pile, Edward K. Hammond. Machy. (N. Y.), vol. 28, no. 10, June 1922, pp. 769–772, 8 figs. Conversion into useful articles of much material found in scrap piles. How Can. Pacific turns ts scrap pile into source of revenue.

SCREW THREADS

Inspection by Optical Projection. Speeding Up Screw Thread Inspection by Optical Projection, Ralph E. Flanders. Automotive Industries, vol. 46, no. 21, May 25, 1922, pp. 1116–1119, 7 figs. Speed and accuracy attained by Hartness screw-thread comparator. Method applied to test cutters and to locate imperfect edges of gear teeth by tracing outline of median tooth section. Paper presented before Am. Gear Mfrs. Assn.

SCREWS

Machine Bolts and. Designing Machine Screws and Bolts, L. T. Rutledge. Can. Machy., vol. 27, nos. 8 and 10, Feb. 23 and Mar. 9, 1922, pp. 26–27 and 24–25 and 29, 6 figs. Feb. 23: Various thread shapes and their respective uses; screw thread as a power medium; thrust factor depending on shape; safety of bolts; pipe threads. Mar. 9: Screw threads for bolts and nuts. Bending stresses; stripping of threads; failure due to shear; lacking devices; effect of vibration; etc.

Milling. The Milling of Screws, H. H. Jeffcott. Engineering, vol. 113, no. 2936, Apr. 7, 1922, pp. 441–442, 5 figs. Account of problems of interest to manufacturer and metrologist. Paper read before (British) Instn. Mech. Engrs.

SEMI-DIESEL ENGINES

Operation. Semi-Diesel Engines (Les Moteurs Semi-Diesel). Technique Moderne, vol. 14, no. 4, Apr. 1922, pp. 145–150, 31 figs. Construction and operation, fuel injection, regulation and general application.

Water Injection in. The Use of Water Injection in Semi-Diesel Oil Engines, R. B. White. Power, vol. 55, no. 16, Apr. 18, 1922, pp. 617–618. Author claims that while water injection is necessary in low-pressure engines, it is not desirable and may be avoided by higher compressions; and that water does free cylinder of carbon, and its occasional use is recommended, even in dry engines.

SEWER CONSTRUCTION

Pneumatic Diggers. Pneumatic Clay Diggers Speed Sewer Tunnel Work, R. A. Lundell. Compressed Air Mag., vol. 27, no. 6, June 1922, pp. 167–168, 3 figs. Development of air-driven clay diggers eliminating picking or blasting, makes possible record progress in tunnel driving.

SHEARS

Hydroelectric Bloom. Hydro-Electric Bloom Shear. Iron Age, vol. 109, no. 16, Apr. 20, 1922, pp. 1078–1079, 4 figs. New method of operation devised for use in mills without steam power.

SHIP PROPULSION

Hydraulic Transmission. The Foettinger Hydraulic Transmission Gear of the Mail Boat "Tirpitz" (Les transformateurs hydrodynamiques "Foettinger" du paquebot "Tirpitz"), Grison. Bul. Technique du Bureau Veritas, vol. 4, no. 1, Jan. 1922, pp. 1–5, 6 figs. Built by Vulcan Shipyards for Hamburg-American Line. Design, operation, and tests of these gears which show efficiency of 90 per cent.

SNOW REMOVAL

Crane Cars. Crane Cars Solve Snow-Removal Problem. Elec. Ry. Jl., vol. 59, no. 20, May 20, 1922, pp. 825–827, 5 figs. Three crane cars designed by Third Ave. Ry., New York City, for general track repair and handling and transportation of miscellaneous materials have been used to increase snow-fighting equipment by addition of wings.

SPRINGS

Automobile. See AUTOMOBILES, Suspension.

Leaf, Modern Manufacture. Modern Methods of Making Leaf Springs, E. F. Lake. Iron Age, vol. 109, no. 20, May 18, 1922, pp. 1343–1346, 6 figs. Mechanical forming machines; tempering furnaces; assembling, testing and inspecting.

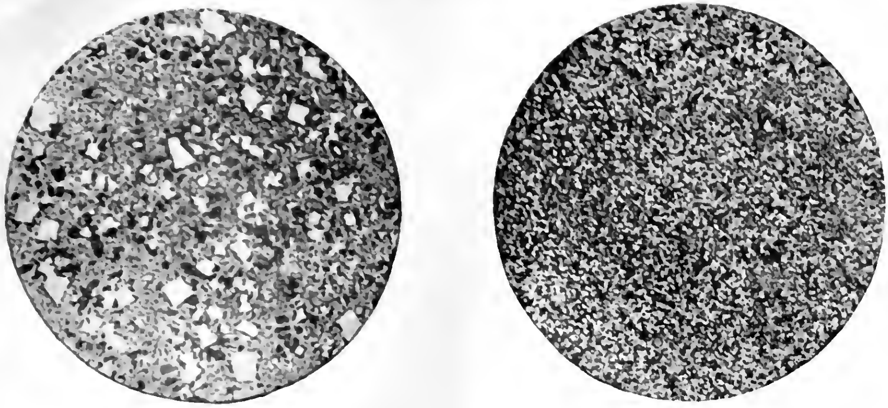
STANDARDS

British, Rail Testing Machines. Falling Weight Testing Machines for Rails. British Eng. Standards Assn., Apr. 1922, no. 103, 1 p.

U. S. Bureau of Standards. What the Bureau of Standards Can Do for You. Factory, vol. 28, no. 5, May 1922, pp. 540–541 and 554, 556 and 558, 3 figs. Indicates scope of service.

STEAM

Consumption, Calculation. Steam Consumption



HIGH GRADE BABBITT CADMAN BEARITE METAL

Microphotographs by Pittsburgh Testing Laboratory.
Magnified 100 diameters. Etched with Nitric Acid.

Effective *versus* Apparent Bearing Surface

The microphotographs above are of bearing metals of identical, and time-proven, composition. That on the left is alloyed in the ordinary way, while that on the right is alloyed to bring out its full bearing properties.

The metals are the same. Which would you buy?

In the metal on the left, the load is carried on the crystals. The matrix simply serves to hold the crystals in place. This is a scientific fact.

In the metal on the right, the crystals are broken up into a uniform network which embraces the full bearing surface. The apparent bearing surface is the same, but the effective bearing surface of Cadman BEARITE is four times that of the metal on the left. The rate of wear of the metal on the left is four times that of BEARITE.

The crystals in the ordinary babbitt are readily removed under the abrasive action of the shaft. The places from which crystals have been removed, even under the delicate process of polishing, can readily be seen in the microphotograph. In Cadman BEARITE, there are no crystals to be removed.

The uniform depressions in the surface of Cadman BEARITE form oil pockets. BEARITE can readily be shown to hold an oil film under conditions which would destroy any other metal.

With the usual alloying process, the metals are just "put together." In the Cadman process, they are scientifically alloyed to bring out every valuable bearing property.

The metals are the same. The cost is the same. Yet one has four times the value of the other. Which are you buying?

Engineering Bulletin M1 is a digest of sixty years' experience in the manufacture of fine bearing metals. It covers the subject of bearing metals in detail.

Accounted For by Indicator Diagram. Power, vol. 55, no. 24, June 13, 1922, pp. 935–937, 7 figs. Development of equations for water rate and application to indicator diagram giving steam that would be used if no condensation occurred.

Production and Use. Production and Use of Steam (Production et utilisation de la vapeur), Victor Kammerer. Bul. de la Société Industrielle de Mulhouse, vol. 87, no. 9, Nov. 1921, pp. 440–464. Discusses fuel, efficiency and losses, automatic stokers, etc.

Saturated. The Behavior of Saturated Steam (Ueber das Verhalten gesattigter Dämpfe), R. Plank. Zeit. fur technische Physik, vol. 3, nos. 1 and 2, 1922, pp. 1–7 and 69–78, 5 figs. Theoretical principles and facts based on experience; empirical equations for heat of evaporation and for pressure curve; tables of dry saturated steam, dry saturated CO_2 vapors, heat of vaporization of ethyl ether.

STEAM ACCUMULATORS

Ruths. The Ruths Steam Accumulator (Der Ruths-Dampfspeicher), R. G. Constam-Gull. Schweizerische Bauzeitung, vol. 79, no. 16, Apr. 22, 1922, pp. 203–207, 13 figs. Built by Vaporackkumulator Co. in Stockholm. Acts as a pressure equalizer and when in operation is filled 95 per cent with superheater water. See also Wärme, vol. 45, nos. 14 and 15, Apr. 7 and 14, 1922, pp. 170–173 and 193–195, 14 figs.

STEAM ENGINES

Extraction. Possibilities of the Extraction Engine. Iron & Coal Trades Rev., vol. 104, no. 2825, Apr. 21, 1922, pp. 567–568, 2 figs. Describes a steam-extraction engine built by John Musgrave & Sons, Ltd., Bolton, Eng., of 650 i.hp. at 160 r.p.m. for maximum extracted steam quantity of about 11,000 lb. per hr. at from 10 to 15 lb. receiver pressure; drives line of shafting by ropes, and is direct-coupled to a 200-kw. d.c. generator.

STEAM POWER PLANTS

Battle Creek. Battle Creek Steam Plant of Consumers Power Company, W. W. Tefft. Power, vol. 55, no. 23, June 6, 1922, pp. 880–885, 6 figs. Plant capacity of 27,500 kw; modern boiler installation with large boilers to operate at high capacity; combined evaporative efficiency of boilers, water backs, superheaters and economizers of 85 per cent on test, and average under load for January of 80 per cent; other outstanding features.

STEAM TURBINES

Reliability and Design. Steam Turbine Reliability and Design. Engineer, vol. 133, no. 3462, May 5, 1922, pp. 486–487, 1 fig. Particular considerations are reliability, economy and first cost.

Starting Up. Putting Steam Turbines in Service. Power, vol. 55, no. 20, May 16, 1922, pp. 756–759, 4 figs. Increasing size of units makes procedure of starting more serious. Features to look out for.

STEEL

Chromium. See CHROMIUM STEEL.

Fracture Test. Fracture Test on Steel to Determine Its Quality, W. J. Priestley. Am. Soc. for Steel Treating Trans., vol. 2, no. 7, Apr. 1922, pp. 620–622, 2 figs. Saw disk about 1¼ in. thick from end of forging or bloom; quench slightly above critical temperature, draw between 900 and 1100 deg. fahr., and break in two. Fracture parallel to direction of forging or rolling will disclose texture of metal. Flake, slag, blowholes and pipe are easily detected.

Rivet, Effect of Sulphur on. Effect of Sulphur on Rivet Steel, E. E. Thum. Chem. & Met. Eng., vol. 26, no. 22, May 31, 1922, pp. 1019–1024, 15 figs. Maximum sulphur now allowed (0.045 per cent) is at least 0.01 per cent below quantity where sulphur will damage strength of well-made rivet steel as far as its performance can be predicted by standard tests.

Stainless. Stainless Steel and Rustless Iron, Herbert Whitaker. Ironmonger, vol. 175, no. 2530, May 13, 1922, p. 106. Rustless iron, rustproofing cast iron and steel, formation of magnetic oxide.

STEEL, HEAT TREATMENT OF

Abrasive Qualities, Effect on. The Abrasive Qualities of Plain Carbon and Alloys Steels, A. M. Cox. Am. Soc. for Steel Treating Trans., vol. 2, no. 8, May 1922, pp. 680–690, 12 figs. Results of tests on effect of heat treatment on abrasive qualities of plain carbon and alloy steels, after having been subjected to various heat treatments.

Annealing. A New Annealing Process for Sub-Pearlite Steels (Ein neues Gluhverfahren fur unterperlitische Stähle), Bengt Kjerrman. Stahl u. Eisen, vol. 42, no. 18, May 4, 1922, pp. 697–700, 3 figs. Annealing of steel to increase its workability by means of cutting tools.

Chrome Steel for Ball Bearings. Heat Treatment of Chrome Steel for Ball Bearings, Haakon Styri. Am. Soc. for Steel Treating Trans., vol. 2, no. 8, May 1922, pp. 718–729, 34 figs. Metallography and important features of process.

Heating and Cooling. Importance of the Proper Heating and Cooling of Steel, John A. Succop. Am. Soc. for Steel Treating Trans., vol. 2, no. 8, May 1922, pp. 673–679, 4 figs. Vital points in this process including temperature, time, surface and mass.

On the Stepped A1 Transformation in Carbon Steel During A Rapid Cooling, K. Honda and T. Kikuta. Iron & Steel Inst., advance paper, no. 8, meeting, May 1922, 13 pp., 13 figs. Experiment and discussion of effect of rapid cooling on A1 transformation point.

STEEL, HIGH-SPEED

Physical Tests. Physical Tests on High Speed Steels, A. H. d'Arcambal. Am. Soc. for Steel Treating Trans., vol. 2, no. 7, Apr. 1922, pp. 586–595 and (discussion) 595–601, 33 figs. Results of series of tensile and transverse tests on two classes of high-speed steel, namely, the 18-per cent tungsten, 1-per cent vanadium type and the 14-per cent tungsten, 2-per cent vanadium grade.

STEEL MANUFACTURE

Acid, Analysis. Analysis Aids Acid Steelmaking, A. C. Jones. Iron Trade Rev., vol. 70, no. 24, June 15, 1922, pp. 1720–1722. Operating schedule and discussion of elements entering into electric furnace process; desirability of accurate control; melter's ability.

Acid Open-Hearth Process. Fine Steels from the Acid Open Hearth, W. P. Barba and Henry M. Howe. Chem. & Met. Eng., vol. 26, no. 20, May 17, 1922, pp. 929–931, 1 fig. Discussion of underlying principles and necessary furnace practice for production of high-grade nickel steel for gun tubes and shafting. Comparison of pig, scrap, and ore processes used in America with all-scrap practice used in Europe. Digest of paper presented before Am. Inst. Min. & Met. Engrs.

British Siemens Furnace Practice. British Siemens Furnace Practice, F. Clements. Iron & Steel Inst., advance paper, meeting May 1922, 19 pp., 14 figs. on supp. plates. Results of tests carried out at Park Gate together with many charts showing characteristics of operation. See also Engineering, vol. 113, no. 2941, May 12, 1922, pp. 579–582 and Iron & Coal Trades Rev., vol. 104, no. 2827, May 5, 1922, pp. 640–659.

STEEL WORKS

Alabama City. Description of the Alabama City Works of the Gulf States Steel Company. Blast Furnace & Steel Plant, vol. 10, no. 5, May 1922, pp. 254–258, 2 figs. This company owns plants and properties which constitute an integrated steel operation from raw materials and fuel to finished product consisting of wire, nails, fencing and bars.

Electric, Adaptable. An Adaptable Electric Steel Company, Sidney G. Koon. Iron Age, vol. 109, no. 18, May 4, 1922, pp. 1196–1202, 10 figs. Two forging plants of different characteristics afford opportunity for handling in each, work to which it is best fitted.

Park Gate Co. Ltd., Rotherham, England. British Siemens Furnace Practice, Fred Clements. Iron & Coal Trades Rev., vol. 104, no. 2827, May 5, 1922, pp. 640–659, 27 figs. Detailed description of entire operation, with tables and graphs on temperatures, and fuel and air consumption, chemical balance sheet of furnace charts, heat balance sheet of furnace charts; outline of furnaces. Paper read before Iron & Steel Inst. See also Engineering, vol. 113, no. 2941, May 12, 1922, pp. 579–582.

STEREOAUTOGRAPHS

Pulfrich. Principles and Use of Stereoautography (Grundlagen und Anwendung der Rambildmessung), K. Lehmann. Gluckauf, vol. 58, no. 17, Apr. 29, 1922, pp. 489–495, 8 figs. Describes stereocomparator, phototheodolite, and the stereoautograph, and their use, especially in connection with aeronautics, on system of Prof. Pulfrich.

STOKERS

Developments. Topical Discussion: Stokers and Their Recent Developments. Assn. Iron & Steel Elec. Engrs., vol. 4, no. 4, Apr. 1922, pp. 163–211. Various notable features brought out by men prominent in industry.

Forced-Draft. Some Notes on the Construction and Operation of Coxe Stokers, John van Brunt. Am. Soc. Heating & Vent. Engrs. Jl., vol. 28, no. 3, Apr. 1922, pp. 298–308 and (discussion) 308–310, 8 figs. History of development, details of present type, and notes on operation.

Marine Boilers. Water-Tube Boiler with Underfeed Stoker for Shipboard. Engineering, vol. 113, no. 2941, May 12, 1922, pp. 581–586, 7 figs. Introduction of water-tube boilers in place of Scotch type makes mechanical stoker possible. Results obtained from installations.

STREET RAILWAYS

Cars, Light-Weight Interurban. Light Weight Interurban Cars, C. T. Dehore. Gen. Elec. Rev., vol. 25, no. 6, June 1922, pp. 352–359, 10 figs. Results from use of light-weight cars by number of different companies.

Edinburgh, England. Edinburgh Tramways Inquiry. Tramway & Ry. World, vol. 51, no. 18, Apr. 13, 1922, pp. 188–190, 2 figs. Gives evidence taken in favor of overhead equipment proposed by municipality and objections raised against it.

Standardization. Standardization Work of the German Society of Street Railways, Etc. (Die Normungsarbeiten des Vereins Deutscher Strassenbahnen, Kleinbahnen und Privateisenbahnen E. V.). Verkehrstechnik, special number, May 1922, pp. 256–274, 32 figs. Standards in effect Apr. 1, 1922, as to rails, poles and track construction, and rolling stock.

STRUCTURAL STEEL

Testing. The Blow Bending Strength and Blow Hardness of Structural Steel (Schlagbiegefestigkeit und Schlaghärte legierter Konstruktionsstähle), W. Muller. Forschungsarbeiten auf dem Gebiete des Ingenieurwesens, no. 217, 1922, 38 pp., 74 figs. partly on supp. plates. Describes test steel and method of carrying out experiments; results of breaking tests, bending tests, hardness tests; connection between mechanical properties and alloying of steels.

SUPERHEATED STEAM

Specific Heat. Specific Heat of Superheated Steam for Pressures of 20 to 30 Atmos. and Saturation Temperature of 350 Deg. Cent. (Die spezifische Wärme des uberhitzten Wasserdampfes für Drücke von 20 bis 30 at und von Sättigungstemperatur bis 350° C), Osc. Knoblauch and Erwin Raisch. Zeit. des Vereines deutscher Ingenieure. vol. 66, no. 17, Apr. 29, 1922, pp. 418–423, 9 figs. Describes experiments carried out in laboratory of Munich Technical High School.

Temperature Measurement. Measurement of Superheat, B. O. Snyder. Power Plant Eng., vol. 26, no. 10, May 15, 1922, pp. 515–516, 2 figs. Types of thermometers used; precautions in taking readings; making corrections.

SUPERHEATERS

Design. Advantages and Calculation of Size of Superheaters As Well As Flue Gas and Waste Steam Preheaters (Vorteile und Grössenberechnung von Dampfüberhitzer sowie Rauchgas- und Abdampfvorwärmer). Wärme- und Kälte-Technik, vol. 24, no. 9, May 1, 1922, pp. 101–102. Mainly deals with superheaters.

T

TAPERS

Standardization. Shall We Standardize Tapers? Am. Mach., vol. 56, nos. 15, 16 and 17, Apr. 13, 20 and 27, 1922, pp. 551–552, 595–597 and 627–629. Opinions of many firms making and using tapered members. Nearly all want a standard.

TEMPERATURE MEASUREMENT

Accuracy. Accuracy in Temperature Measurements, Horace C. Knerr. Forging & Heat Treating, vol. 8, no. 5, May 1922, pp. 235–237. Accuracy sseential because of variations in steel; potentiometer pyrometers recommended; cold junction compensation; remarks on thermocouples with reference to standardization.

TESTING MACHINES

Penetrometer. Apparatus for Comparing the Hardness of Pitches and Bitumens. Engineer, vol. 133, no. 3456, Mar. 24, 1922, pp. 338–339, 2 figs. Describes the Hall-Marriott automatic penetrometer, designed to exclude human element in determination of consistency of plastic substances used in road construction.

TEXTILE MACHINERY

Maintenance. Maintenance of Textile Machinery, Edwin H. Marble. Mech. Eng., vol. 44, no. 5, May 1922, pp. 311–312. Purpose of ball bearings and importance of proper lubrication. Common abuses and suggested corrections.

Revolving Flat Cards. Modern Shop Practice in the Building of Revolving Flat Cards, F. E. Banfield, Jr. Mech. Eng., vol. 44, no. 5, May 1922, pp. 301–304, 310, 14 figs. Details of special machines developed for work. Production cost per unit lowered by efficient shop arrangement, careful machine designing and standardization.

TIRES, RUBBER

Cord. The Superiority of Cord Tyres, C. M. Gautier. India-Rubber Jl., vol. 63, no. 18, May 6, 1922, pp. 7–8, 4 figs. Superiority of this type shown by experiments with appliances which subject tires to conditions actually met in service.

TINNING

Hot Tinning. Hot Tinning, S. R. Gerber. Metal Industry (Lond.), vol. 20, nos. 16 and 17, Apr. 21 and 28, 1922, pp. 369–371 and 396, 2 figs. Description of reorganization of department for tinning steel cans.

TOOLS

Calculation of Circular. The Calculation of Circular Form-Tools: An Empirical Formula, Mech. World, vol. 71, no. 1847, May 26, 1922, pp. 375–376, 4 figs. Development of simplified empirical formula for circular form tools.

Ring. The Economical Design of Ring Tools, H. Baker. Machy. (Lond.), vol. 20, no. 504, May 25, 1922, pp. 236–238, 2 figs. Formulas for figuring labor costs in consideration of circular form tool.

W

WAGES

Payment Plans. Wage-Payment Plans—A Discussion, Harrington Emerson. Management Eng., vol. 2, no. 6, June 1922, pp. 370–372, 1 fig. Exposition of six plans of payment with some detail of author's plan.

WASTE HEAT

Utilization. The Utilization of Waste Heat From Electrical Generating Stations, F. H. Whysall. Practical Engr., vol. 65, no. 1823, Feb. 2, 1922, pp. 69–70. Possibility of locating industrial plants about generating stations to use waste heat, and difficulties arising. Paper read at joint meeting of Instn. Elec. Engrs. and Instn. Heat. & Vent. Engrs.

WASTE UTILIZATION

Metal Waste. Using Wastes of the Metal Industry (Nutzbarmachung von Abfällen in der Metallindustrie), Karl Micksch. Bergbau, vol. 35, nos. 12 and 13, Mar. 23 and 30, 1922, pp. 416–419 and 447–449. Discusses remelting of metal scrap of various kinds, also sheet metal for detinning.

MECHANICAL ENGINEERING

Volume 44 September, 1922 No. 9

The Oil Supply of the World

Estimates of the Oil Resources of the Various Regions of the Earth The Economic Future as to Oil in the United States—Measures Necessary to be Taken in Order to Increase and Conserve the Domestic Supply

By DAVID WHITE,[1] WASHINGTON, D. C.

THE question is asked, Why is the United States, whose market is now suffering from a slight excess of oil supply, especially concerned about how much oil there is in our own country and the world? Are we trying to corner the world's oil? Do we fear harmful competition from countries more richly supplied? Are we running short of oil, or is there oil famine in other parts of the world that threatens to draw too heavily on our supplies in competition with our own people, with consequent raise of oil prices to levels harmful to the consumers of this country? The concern of the public in the economic problem of oil supplies arises from the following outstanding features of the situation, which give the question an incisive significance to every American user of oil.

To date the United States has furnished nearly two-thirds of all the oil yet taken from the ground in the world—5.5 billions of barrels out of a total of 8.5 billions. Our American fields are now pouring out 62 per cent of the world's annual supply, while our country is using over 75 per cent of that total supply. In other words, the United States requires over 115 million barrels more than it produces; for, whereas our output now approximates 470 millions yearly, our requirements, even during the business stagnation of 1921, called for 525 millions. Our autovehicle program, already passing 10 million cars, is still growing; our merchant ships must burn oil to compete with those of other nations; there are bound to be more tractors and trucks, pumps, small machinery and miscellaneous equipment; and air service is destined to become an everyday necessity. Everywhere, except perhaps in the Navy, the demand for even more oil is in evident prospect. Nothing can check the increase more than momentarily, except high prices due to scarcity of oil or high costs of production or importation—that is, the greater expense of obtaining the oil.

Where will the oil to satisfy these requirements come from year after year, and how long can we keep up the pace? These are plain, common-sense business questions, predicted on our present oil requirements as an established fact and on the suggested possibility that our prodigal spending of our petroleum heritage may cause its too rapid depletion if not its early exhaustion in the midst of our spendthrift career, and at some untoward moment send us as beggars to foreign countries for the precious fluid necessary not only to satisfy our extravagant habits, but even to sustain our industrial prosperity, our standards of living, and our civilization.

Obviously there is only one first thing to be done, and that is for the nation to proceed in the nation's business just as the business man proceeds under similar conditions in his private business, namely, to take account of stock, to find out how much oil there is left in the United States and then to learn as nearly as possible how much oil there is in the rest of the world and where the principal deposits or reserves are located, due consideration being given to probable availability and conditions of production of these reserves.

No apology, therefore, is needed for the searching appraisal and careful estimate recently made of the oil reserves remaining in the ground recoverable by present methods in the United States, nor for its publication for the information and advice of the industry and the country at large. The justification of the formulation of estimates of the oil reserves in other countries, based upon long and painstaking studies of the available data relating to the oil reserves and relative oil possibilities of those other regions of the world, is evident. Such information is indispensably requisite for understanding the present economic situation.

Known Oil Resources of the World

The oil reserves to be found in the regions of the earth where oil has already been proved to exist in commercial amounts were in 1920 estimated by Eugene Stebinger and the author at 43 billions of barrels, as listed in Table 1. This calculation is based upon a review of the available data as to the regional geology the structure, the character and composition, thickness, relations, and alteration of the sedimentary deposits of the different basins, the information as to local and minor folding, and as to surface indications of oil, and finally the records as to developmental tests or actual production. The consideration of the geology of other regions in which oil has not yet been proved to be present in commercial amounts led to the formulation of an additional estimate of 17 million barrels for these regions, placing the total estimate for the world's oil reserves in the ground and recoverable by present methods at 60 billions of barrels. As stated at time of publication, these estimates are necessarily highly speculative and, in spite of the care and study given to their preparation, are subject to great range of error, especially with reference to non-producing countries and to those concerning which the geologic information is meager. They are avowedly conservative. From data subsequently reviewed and on consideration of further information in hand, the author is disposed to regard the estimates for eastern Siberia, Sakhalin, India, Assyria, and Arabia as much too low, with the probability that the oil content of South America will exceed 13 billions of barrels. He accordingly believes that an estimate of 70 billion barrels for the world's total resources is conservative.

TABLE 1 OIL RESOURCES OF REGIONS OF THE WORLD KNOWN TO CONTAIN COMMERCIAL DEPOSITS, AS ESTIMATED BY EUGENE STEBINGER AND DAVID WHITE

Country or region	Millions of barrels
United States and Alaska	7,000
Canada	995
Mexico	4,525
Northern South America, including Peru	5,730
Southern South America, including Bolivia	3,550
Algeria and Egypt	925
Persia and Mesopotamia	5,820
S. E. Russia, S. W. Siberia and the region of the Caucasus	5,830
Roumania, Galicia and western Europe	1,135
Northern Russia and Sakhalin	925
Japan and Formosa	1,235
China	1,375
India	995
East Indies	3,015
Total	43,055

The most important oil regions outside of the United States are believed to be located in Mexico, Venezuela, Colombia, Bolivia, Argentina, Russia, Mesopotamia (together with western Persia), Assyria and Arabia, the East Indies, China and Eastern Siberia (including northern Sakhalin), the Japanese Empire, India, and probably northern Africa. A forecast as to the proportions of light and heavy oils in these great regions would be extra hazardous, but a review of the results of exploration, combined with the consideration of the regional geology, the character of the formations and the stages of alteration, tends to confirm the very natural assumption that the

---

[1] Chief Geologist, U. S. Geological Survey.

Presented at the Regional Meeting of the Local Sections of The American Society of Mechanical Engineers, Kansas City, Mo., March 6 and 7, 1922. Slightly abridged.

production of all of these regions will include moderately light, and in some regions very light, oils as well as, in nearly all cases, fuel oils.

A review of the map compiled by Mr. Stebinger and used in numerous discussions, including the author's paper in the Annals of the American Academy of Political and Social Science for May, 1920, indicates a concentration of the world's oil resources in the northern subtemperate and tropical regions of the earth. Many of the great reserves are distributed along the north Pacific border, the region of the Indian Ocean, and the western Atlantic. Most of them are easily tributary to the principal routes of maritime world trade. It is likely that further investigation will show considerable reserves not only in North Africa, but along the west African coast and in Brazil—in other words, on the borders of the south Atlantic.

Concerning the restrictions by which the nationals of the United States are excluded from free participation in the development of the oil deposits of a large part of the world, and in the Eastern Hemisphere especially, to which the author has given some attention, authentic information will be found in two statements prepared by the Department of State.[1] Most American readers are aware of the efforts of our Government to secure entry for American oil companies in Mesopotamia and again in Djambi, which represents the Dutch East Indies. A satisfactory compilation of concessionary as well as political control of the oil resources outside of North America is at present nearly impossible, but it appears practically certain that two-thirds of the world's oil reserves outside of the United States are not open to development by American companies. In some countries the "open door" is not so open as it appears to be. Some of these reserves may in time of peace be available, if needed, to our citizens at a price, but priority of right, if not permanent reservation, will be given to the navies and militaries of the different countries. Undoubtedly whenever our citizens become dependent for oil on foreign reserves in the hands of rival nationals, they will restore with ample interest all the profits enjoyed through many years by the American exporter. Any protection that we may then need should be assured in advance.

Oil Resources of the United States That Are Recoverable by Present Methods of Exploitation

Having considered the wealth of oil in foreign countries which, according to the very conservative calculations given above, is sufficient to meet the present rate of consumption requirements of the aggregate countries outside of the United States for 215 years, we come to the important question as to the sufficiency of the oil deposits of our own country to meet the whole or a considerable part of our own requirements for the future. In other words, what is the economic future as to oil in the United States? Are our supplies ample and shall we be independent, continuing our role as the world's great producer and distributor of petroleum and its products, or are our reserves so rapidly becoming exhausted that we are in the way to become a mendicant for oil among the nations which we have served with such prodigal generosity?

To answer this question, an appraisal of the domestic oil resources in the ground recoverable by present methods of exploitation has just been completed. Taking advantage of the great expansion of oil-field exploration in the United States in the last few years, the results of widespread wildcatting in regions of merely possible as well as probable territory, the proving of entire oil fields as well as pools, the training of hundreds of geologists and engineers specialized in the problems of the geologic occurrence of petroleum, and desiring to apply the best methods as well as the experience developed through oil-field examination and estimation in appraisal or depletion, in accordance with the requirements of existing tax laws, the United States Geological Survey, a year ago, invited the American Association of Petroleum Geologists to appoint from its membership representatives to serve with the oil geologists of the Survey in a joint committee for the estimation of the oil resources of the United States. With the joint committee thus promptly formed, there worked in heartiest coöperation, through sub-committees covering different areas or states, or in direct collaboration, a large number of state geologists, consulting specialists and company geologists especially familiar with the stratigraphy, structure, and mode of occurrence of oil in the different fields. After nine months of compilation, study and discussion, the estimates were reviewed and revised in joint conference, and in January of this year were made public by the Director of the Geological Survey as given in Table 2.

TABLE 2 ESTIMATED OIL RESERVES OF THE UNITED STATES BY STATES OR REGIONS

	Millions of Barrels
New York	100
Pennsylvania	260
West Virginia	200
Ohio	190
Indiana and Michigan	70
Illinois	440
Kentucky, Tennessee, northern Alabama, and northeastern Mississippi	175
Missouri, Iowa, North Dakota, Wisconsin, and Minnesota	40
Kansas	425
Oklahoma	1,340
Northern Louisiana and Arkansas	525
Texas, except Gulf coast	670
Gulf coast, Texas and Louisiana	2,100
Colorado, New Mexico and Arizona	50
Wyoming	525
Montana, Nebraska and South Dakota	100
Utah, Nevada, Oregon, Washington, and Idaho	80
California	1,850
Eastern Gulf Coastal Plain and Atlantic Coast States	10
Total	9,150

These estimates are, naturally, most accurate in those parts relating to proved territory, for which data invaluable for such calculations are now available. In that part relating to probable territory they represent the balanced judgment of a group of chosen specialists including geologists particularly familiar with the regions and their history. The greatest errors may fall in those portions of the total which relate to merely "possible" territory, especially in regions and states in which oil has never yet been proved to be present in commercial amounts. As stated by the author in a discussion of the subject at the New York meeting of the American Institute of Mining and Metallurgical Engineers, in February, the errors of excess in the estimates for disappointing regions are likely, on the whole, to be balanced by the deficiencies in others.

It may be of interest to engineers, who represent the great oil-consuming industries, to note that of the 9 billion barrels which, as of March 15, 1922, should remain in the ground recoverable by present methods, rather more than 4 billion barrels belong to the heavy group containing the fuel oils. Of the class containing the lighter oils about 725 million barrels are believed to remain in the Appalachian states, and 40 million barrels in the Lima-Indiana region. The fuel oils are largely to be found in the Pacific Coast, the Rocky Mountain and the Gulf states.

Economic Situation of Oil as It Affects the United States

In the United States we have at the present moment produced a total of $5\frac{1}{2}$ billion barrels of oil. We have therefore used up more than one-third of our estimated original heritage of oil. In 1921, a year of stagnation of American oil production, we drew out nearly 470 million—practically half a billion—barrels of oil from our reserves, which are now calculated at 9 billion barrels. Contrasted with our more than 5 per cent rate of annual depletion, the rest of the world withdrew in 1921 not much over 280 million from its store of over 60 billion barrels, or less than half of one per cent of its reserves recoverable by present methods. In other words, the reserves of the rest of the world would stand the present rate of drain for over two centuries. From the standpoint of world distribution of oil and the relations of our reserves to those of the rest of the world, an error of 2 or 3 billion barrels—4 to 6 years' supply—in the committee's estimates of the oil reserves of the United States is comparatively insignificant.

The coöperative committee expressly affirms—and it is well known in the profession—that not all the oil pools in the United States will have been discovered a generation hence. On the other hand, the committee takes great care to point out that while our reserves would not meet our present rate of consumption demands for 20 years, if they could be taken out of the ground fast and cheaply enough to supply our market (a conditioning clause that has gen-

Restrictions on American Petroleum Prospectors in Certain Foreign Countries. Message from the President of the United States, May 16, 1921. Senate Document 11, 67th Congress, 1st session.

Oil Prospecting in Foreign Countries. Message from the President of the United States, June 13, 1921. Senate Document 39, 67th Congress, 1st session.

erally been lost sight of by the press and the public), this country will be producing oil for as long as 75 years to come.

Since oil cannot so rapidly be located and taken from the ground, it follows with certainty that, according to the laws of oil production, the annual oil output of the United States must at an early date pass its peak and enter upon a long-drawn-out period of general though fluctuating decline to ultimate exhaustion, except so far as fields in great numbers may be rejuvenated by better methods of mining. Opinions differ as to how soon the production peak will be passed; but most geologists believe that within a few years, perhaps less than five, we shall in the normal course enter on a period of waning fields in increasing number, with discoveries more infrequent and in general more costly. The date of passage of the peak depends largely on the demand for oil and the reflected oil prices. If supplies from foreign sources continue adequate and cheap for a long time the passage of the peak may be insensible though early; but should they be seriously curtailed or largely cut off for a considerable period in the near future, we probably shall then see our operators driven by high prices to the greatest maximum, in which an overoptimistic industry will eventually have found it has passed the peak.

A large portion of the public does not yet fully recognize that the United States is already dependent upon foreign oil to meet its still growing requirements. Our oil importations which were 18 million barrels in 1913, grew to 38 million in 1918, 53 million in 1919, 106 million in 1920, and 125 million in 1921. A small part only (9 million barrels) of this amount is offset by exportation of crude petroleum from the United States. In short, in a period of industrial depression we have imported one-fourth as much as we produced. Nearly all of this oil comes from Mexico, and that is why Americans are so profoundly interested in Mexican oil.

The present production in Mexico, amounting to about 195 million barrels in 1921, is mostly drawn from a relatively small number of wells located along a single axis of folding in which a thick limestone, the Tamosopo, is caverned by solution and, in the structurally high points, gorged with gas and oil under most tremendous pressure of salt water. No wells of such enormous production are known in any other part of the world. It is common knowledge that most of these wells have gone or are now going to salt water, and on the basis of this fact as differentially interpreted in the light of other geologic conditions in the field, it is believed by many oil geologists, including some of high repute, that the greater part of Mexico's present phenomenal production is on the verge of approximate extinction. It is practically certain that, while some new discoveries of Tamosopo oil may come to the aid of the rapidly failing pools, sooner or later the production of oil from the world-record-breaking Tamosopo limestone gushers will wane, and the remaining portion of Mexico's 4 to 5 billion barrels of oil reserves, as estimated, must be won by the sweat of the oil operator's brow from wells of the ordinary type. The magnitude of the task of developing enough oil fields of the "common or garden variety" in Mexico to take over the load of an annual production of 195 million barrels which was produced from less than 300 wells in 1921, may be inferred from the fact that in 1908, when for the first time the production of oil in the United States amounted to so much as 175 million barrels, over 140,000 wells contributed to the output. This number is, of course, subject to sweeping and radical discount for rapidity of development and freshness of production. It would take over 10 Haynesvilles or a group of 4 Mexias or 14 Salt Creeks, all running full blast, simultaneously, and all continuously maintaining their January rates of production, which, of course, is impossible. It is difficult to estimate the oil price stimulus necessary to develop a production of 200 million barrels of oil in Mexico from wells of the ordinary type under existing transportation, climatic, and industrial conditions within five years. The prices requisite would certainly be most encouraging for the production of oil from shale in this country.

The collapse, or better, the great slump, in Mexican production, which seems sooner or later inevitable, can hardly fail to react on our own oil-field production, probably driving it to the limit; and it is likely that in the early period of this strain the annual output of petroleum in the United States will pass its peak. Beyond this point our need for more foreign oil is likely to spring up from our decreasing domestic production more than from further growth of our consumption requirements. In this period relief must come from other foreign oil fields and from the production, by distillation, of shale oil, on whose adequacy and on whose yet undetermined cost we may be obliged to rely for protection against transoceanic importations at transoceanic prices beyond our control. Too great an advance in price will, of course, check our use of oil and bring it within the bounds of practicably available supplies from all sources, at prices then viewed as practicable. The oil we cannot afford to buy we will do without.

The extent to which failure of Mexican production may be disastrous to this country depends on the completeness of the slump. It depends also, especially in the early stages, on the extent to which the American oil companies have developed or can rapidly develop considerable available production in other foreign regions on the one hand, and, on the other hand, on the extent to which, as the results of scientific research and energetic commercial application, better methods of oil mining are developed and proportions of the oil not recoverable by present methods of extraction are then taken for the ground. As is well known, in most fields and sands the larger portion of the oil remains locked up in the pores of the reservoir sands, even when the fields are "played out" and abandoned. It is believed by engineers who have given most study and experimentation to the subject that an additional recovery of 40 to 80 per cent over that obtained by present methods will ultimately be possible in many of the fields.

Economic Deductions

Around the constructive economic deductions to be drawn from a review even so superficial and elementary as this summary of the high points of the situation as to oil resources, it is to be seen that—

1 The need of foreign oil reserves available for continued use in the United States is obvious.

2 Waste in producing, in transporting, and in using oil should be prevented or curtailed as far as is economically practicable.

3 Increased concentration of thought and experimentation on the more efficient use of the oil now available and on the production of commodities of greater efficiency are economically urgent. On every occasion consideration should be given to the general abandonment of oil to generate steam, in favor of the three-times-as-efficient Diesel motor or some other still more effective substitute.

4 More intense and more widespread researches in the production of liquid hydrocarbons through processes—so-called low-temperature carbonization—aimed at the more efficient use and the wider adaption of our bituminous and lower-rank coals are important.

5 The development on a commercial scale of an oil-shale industry deserves earnest and wise consideration. Naturally there will be waste and loss of this shale through mining first the richest beds, just as takes place in our coal fields. As has been pointed out by Requa and others, the production of oil from oil shales is a matter of mining and retorting ton by ton and predicates the gradual building up of an industry which, to replace one-third of our present petroleum output, would require men, cities, mining plants, machinery, transportation, water, etc., roughly equal to one-third of our bituminous-coal-mining industry. It is a gigantic task requiring years and enormous capital. Above all it requires planning through research, through experimentation, and through patient trial on a commercial scale, with the closest attention by engineers of all kinds to costs as well as products, with the object of placing the industry on a successful basis as a going concern as soon as prices of crude petroleum and conditions as to prospective supplies permit. Studies should be made to show what prices for crudes of different grades will justify the systematic development, in different regions, of oil-shale production. Shale oil, by which is meant artificial petroleum obtained by distillation of oil shale, may be looked forward to as a stabilizer of domestic prices as well as an economic backstop in oil. Eventually, and especially as foreign supplies available to the United States becomes scarcer or too costly, it should guarantee our ultimate independence in oil, and, to this extent, our industrial and social prosperity as well.

6 The recovery of a much larger portion of the oil in the reservoir rocks than is obtained by present methods is an imperative necessity, demanding the faithful, the intelligent, and the immediate consideration of the states and of the Government, as well as of the oil industry.

Mechanical Refrigeration of Railroad Cars

The Technical, Economic and Operating Aspects of Various Attempts to Employ Mechanical Refrigeration in Railroad Refrigerator Cars, Together with Details of a Proposed Dense-Air System for That Purpose

By W. M. Baxter,[1] Chicago, Ill.

THE subject of mechanical refrigeration as applied to railroad equipment is fraught with tremendous difficulties. First, the physical achievement of a successful mechanical process which will meet the multifarious demands of modern railroad transportation has not yet become a fact. Second, the economics of the problem are such as to lead the author to believe that it will be some time before a practical refrigerating machine can be applied to individual refrigerator cars. Third, from a railroad operating viewpoint any mechanically refrigerated railroad equipment must be held in specified traffic. This is a serious drawback because of the lack of universality of its use, and especially in its acceptance in interchange.

Again, being mechanical, such equipment must have the attention of attendants who must be specifically and practically trained in its maintenance and operation, and even with the most practical achievements along these lines it would be a long time before such a piece of railroad equipment would be heralded by the American railroads.

Fig. 1 Arrangement of Machinery of Absorption-Refrigerating System at End of Car

Refrigerating Machines

Refrigerating machines, or heat pumps, are machines which will carry heat from a cold to a hotter body. (This statement is not at variance with our knowledge that heat does not flow of itself from a cold body to a hotter body.) This, as the second law of thermodynamics asserts, cannot be done by a self-acting process, but it can be achieved by the expenditure of mechanical work. Any heat engine will serve as a heat pump or refrigerating machine if it is forced to operate in such a way as to trace its indicator diagram backward so that the area of the diagram represents work *spent on*, instead of *done by*, the working substance. Heat is then taken in from the cold body and is rejected to the hot body.

The standard systems of mechanical refrigeration are:

1 *The Dense-Air System*, so called because the air which is the refrigerating system is never allowed to fall to atmospheric pressure. This is done in order to reduce the size of the cylinders and pipes through which a given weight of air may be circulated. This process does not depend upon the liquefaction of the air, as it is not liquefied but simply compressed and expanded adiabatically.

2 *The Compression System*, using ammonia, carbon dioxide, sulphur dioxide, ethyl chloride, methyl chloride, etc., so called to distinguish it from the third system because a compressor is used to raise the pressure of the vapor and deliver it to the condenser and there liquefy it, after removing it from the evaporator or expander.

3 *The Absorption System*, using ammonia and so designated because a weak water solution removes the vapor from the expander or evaporator by absorption. The richer aqua ammonia so formed is pumped into a high-pressure chamber (called a generator) in communication with the condenser where the ammonia is discharged from the liquid solution, or rich liquor as it is called, to the condenser by heating the generator, to which the solution is delivered by the only moving part in the process, namely, a slow-moving pump.

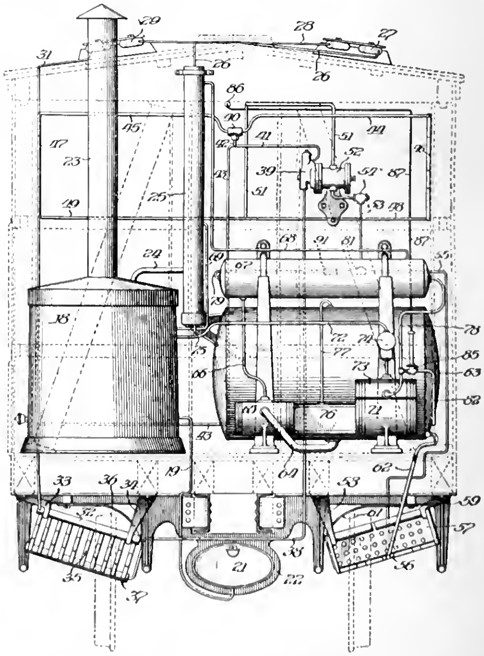

Fig. 2 Later Modifications of Car-Refrigerating System Shown in Fig. 1

The coefficient of performance of refrigerating machines is expressed by the ratio:

$$\frac{\text{Heat extracted from the cold body}}{\text{Work expended}}$$

This ratio may be employed in estimating the merits of a refrigerat-

[1] President, Baxter-Stewart Refrigerator Transport Co.; Vice-President, Ideal Truck Equipment Co.

Abridgment of paper presented at a joint meeting of the Metropolitan Section of the A.S.M.E., and the American Society of Refrigerating Engineers, New York, May 16, 1922. All papers are subject to revision.

ing machine from the thermodynamic point of view. When the limits of temperature T_1 and T_2 are assigned, it is very easy to show that no refrigerating machine can have a higher coefficient of performance than one which is reversible according to the Carnot cycle; for let a refrigerating machine A be driven by another, B, which is reversible and is used as a heat engine in driving A, then, if A had a higher coefficient of performance than B, it would take from the cold body more heat than B (working reversed) rejects to the cold body, and hence the double machine, also purely self-acting, would go on extracting heat from the cold body in violation of the second law. Reversability, then, is the test of perfection in a refrigerating machine, just as it is in a heat engine.

When a reversible refrigerating machine takes in all its heat, namely, Q_2 at T_2, and rejects all, namely Q_1 at T_1, then, representing the heat equivalent of the work done by $W = Q_1 - Q_2$, the coefficient of performance is as already defined:

$$\frac{Q_2}{W} = \frac{Q_2}{Q_1 - Q_2} = \frac{T_2}{T_1 - T_2}$$

hence—and the inference is highly important in practice—the smaller the range of temperature, the better the performance. To cool a large mass of any substance a few degrees will require a much smaller expenditure of energy than to cool, say, one-fifth of the mass through five times as many degrees, although the amount of heat extracted is the same in both cases. If it is desired to cool a large quantity of water or air, for example, it is better to do it by the direct action of a refrigerating machine working through the desired range of temperature than to cool a portion through a wider range and then let it mix with the rest. This is only another instance of a general principle that any mixture or contact of substances at different temperatures is thermodynamically wasteful, because the interchange of heat between them is irreversible.

The foregoing explains why it is mechanically more efficient to produce refrigeration on a large-quantity basis than on a small. In consequence, the amount of energy and machinery in proportion to the refrigerating effect had from a small machine on a refrigerating car is thermally out of proportion to the work done.

European Attempts at the Mechanical Refrigeration of Railroad Cars

The year 1912 marks approximately the beginning of serious attempts at mechanical refrigeration of railroad cars. The first effort that achieved any degree of success was that attempted by the chief of motive power and rolling stock of the Moscow-Kazan Railroad of Russia. Here a semi-absorption process was employed, consisting of refrigerating or expander coils located in the roof of the car and a connection on the outside leading from a drum of anhydrous ammonia, with a suitable expansion valve interposed. The other end of the refrigerating coil was conducted to a crude absorber located underneath the car. This absorber was in reality nothing more than a water tank having an aspirator tube placed therein. To start the process in operation it was only necessary to open the expansion valve and expand the gas in the refrigerating coil; the affinity of the water for the gas in the absorber maintained the back pressure and created the low-pressure side of the machine. It was the intention of the railroad to take the aqua ammonia thus formed in the absorber to a stationary regenerating plant and there distill off and reliquefy the anhydrous ammonia and charge it into suitable receptacles or drums which would be kept on hand and reapplied to equipment passing these points, which latter would virtually perform the same function as re-icing stations. This process failed because it was considerably cheaper to use natural ice for cooling purposes.

While attached to the American Army of Occupation as a major of engineers, the author was on one occasion sent to Poland where he saw in Warsaw an interesting car built in 1912 at Cologne, Germany, for the Russian Government Railways from the designs of M. Humboldt. In the central compartment of this car was a 10-hp. oil engine which drove an ammonia compressor of 4 tons refrigerating capacity. The condensing coils were placed under a sunshade roof on top of the car. No water was used for condensation, the day temperature of the atmosphere being depended upon to wipe off the heat of compression and thus liquefy the ammonia. The liquefied ammonia was passed to various expansion valves, one being located in each of the four refrigerating rooms into which the car was divided—two at each end of the engine compartment. By manually controlling these expansion valves different temperatures could be maintained in each of the various rooms if desired. According to a German railroad official in Warsaw, the cost of operating this car was about 80 per cent more than it would have been had natural ice been employed.

At Mayence on the Rhine, the headquarters of the French Army of Occupation, the author observed a rather new departure in car refrigeration, consisting of three insulated cars placed ahead of a central car provided with a refrigerating plant which was followed by two insulated cars. These cars were built and tried out in 1913. The traffic handled was butter and the service was from Kurgan on the Siberian border to Riga on the Baltic, a distance of about 1500 miles. The temperature maintained in the cars was about 35 deg. fahr. Brine was pumped through piping and coils from the central plant which consisted of a complete refrigerating unit designed by the Linde Company, of Wiesbaden, Germany, one end of the car being partitioned off to serve as a sleeping room for two attendants. The machinery consisted of two double-acting ammonia compressors direct-connected to Diesel engines, ammonia condensers, a brine cooler, and two pumps for brine and for cooling-water circulation, respectively. A fan ventilator in connection with the condenser was set in operation when the train was standing, as otherwise the air passing through the louvres in the upper side walls of the car was not sufficient. A reservoir of cooling water was located beneath the car, as also were water-cooling radiators for the motors.

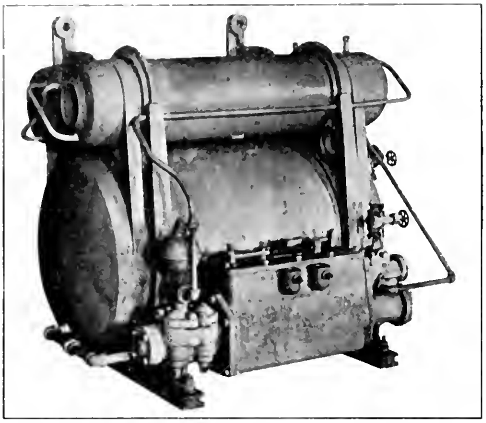

Fig. 3 Secondary Absorber and Temperature Exchanger of Fig. 2

The Author's Earlier System of Mechanical Car Refrigeration

In 1913, when connected with the Canadian Pacific Railroad at Montreal as assistant to the general manager, the author began the study of mechanical refrigeration for railroad cars and built an absorption-system car, which was followed by two more cars constructed by him in the United States. The condenser and absorber were located underneath the car and the source of energy was a slow-burning charcoal fire.

Fig. 1 shows the arrangement of the machinery. The tank on the right is the secondary absorber, while on the left is placed the generator enclosed within an asbestos-insulated jacket. Resting on the generator is seen a portion of the charcoal magazine, which occupies the entire space across the upper end of the car and holds 1500 lb. of charcoal, or enough for twelve days' continuous operation. In the center on the floor is seen the specially constructed ammonia gas-driven circulating pump of the author's design. Above it is located the float regulator which controls the level of the liquor in the generator.

Fig. 2 shows the modifications later made in National Refrigerator Co. Car No. 1003. It was found necessary to add an analyzer and increase the temperature-exchanger capacity. Charcoal was

also abandoned as a fuel in favor of petroleum. The analyzer is shown at 26, while 63 is the secondary absorber, 57 the primary absorber, 67 the temperature exchanger, 35 the condenser, 18 the generator, and 25 the petroleum tank. Fig. 3 shows photographically the secondary absorber and temperature exchanger of Fig. 2.

The construction of the generator is shown in Fig. 5. This consisted of a conical coil of pipe surrounding a kettle hung by means of a trunnion and provided with one central large flue. The rich liquor was pumped into the conical coil first, and as the ammonia gas was distilled off it passed up through three take-offs from various points in the coil to a dome. The other end of the coil was led into the top of the kettle of the generator and there further fractional distillation carried on, the gas passing off through the dome to the analyzer and the condenser. A pipe led out from the generator kettle at the height it was desired to hold the weak-liquor level. This ran to the valve-controlling mechanism of the pump and thence to the power end of the pump, which was driven by the weak liquor and some additional gas.

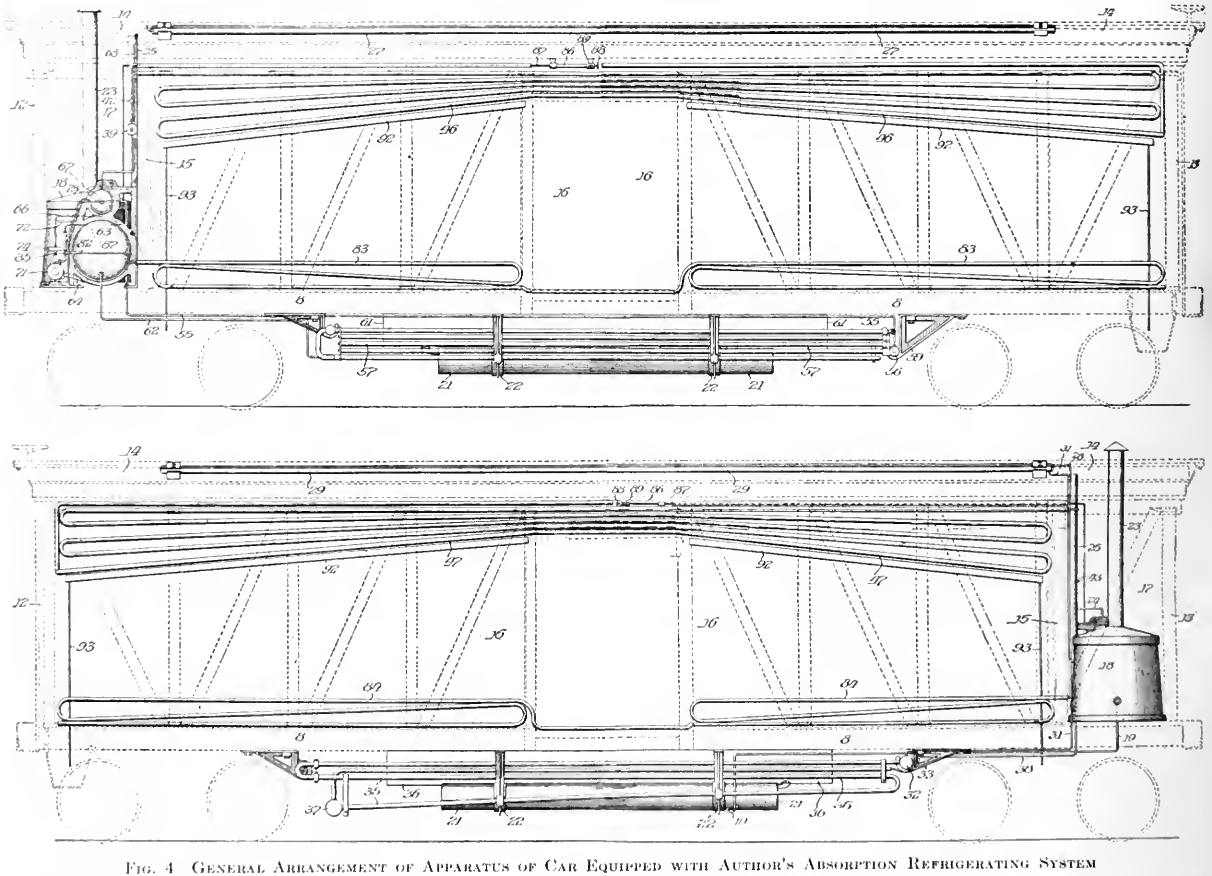

Fig. 4 General Arrangement of Apparatus of Car Equipped with Author's Absorption Refrigerating System

(Upper figure shows absorber underneath car; lower figure, of opposite side of car, shows condenser underneath car. Refrigerating coils are shown on upper side walls and heater coils at lower; superheat-dissipating coils on roof of car, operating mechanism at end.)

Fig. 4 shows the general placement of the various elements of the apparatus. Underneath the car in the upper view is seen the absorber, while in the lower view—of the opposite side of the car—is seen the condenser. Within the car itself on the upper side walls are located the refrigerating coils, while the heater coils are positioned along both sides the lower sides of the side walls. On the roof of the car are placed the superheat-dissipating coils, and in one end of the car is located the operating mechanism.

This car operated successfully on one occasion for nine consecutive days without attention, standing still. The temperature was very evenly maintained at between 32 and 34 deg. fahr. and as low as 26 deg. was reached with an outside temperature of 80 deg. The car was empty.

Fig. 6 shows a diagrammatic plan of the process. Functioning as a refrigerator the operation is as follows: The charcoal magazine is first filled with crushed charcoal; the generator *B* is then filled with a rich charge of aqua ammonia and the secondary absorber to about one-third of its capacity. The fire being lighted, fractional distillation takes place and the gas thus expelled passes to the analyzer through pipe *F*, where a certain amount of dehydration takes place. The gas passes on to the condenser *G* and is liquefied in the header which connects to the automatic expansion valve *H*, the latter not opening until 15 lb. gage pressure has been reached. This retains enough pressure to start the pump automatically. The liquefied ammonia passes through the expansion valve and is expanded in the refrigerating coils *I*, *I*, passing from there to the absorber *J*. The weak liquor leaves the generator through the pipe *K* which projects into the kettle of the generator sufficiently high to obtain the minimum level of liquid desired. This hot weak liquor is conducted to the temperature exchanger *L*, where it meets the cold rich liquor coming from the absorber *J* and which is being pumped by the pump *C*. It gives up its heat to this rich hot liquor and is cooled by the countercurrent of cold strong liquor. It is then sprayed into the primary absorber *N* by means of a nozzle *M* and is further cooled by radiation by the coils *O*, *O*. It is thence conducted to the top of the absorber *J* and sprayed into this chamber. The pump is gas-and-weak-liquor driven and is controlled by the float regulator *Q*. The exhaust from the pump is conducted to a secondary counter-current temperature exchanger where most of its heat is absorbed by the cold rich liquor on its way to the primary temperature exchanger *L*, which liquor is finally conducted into the absorber tube *N* and thence taken up. The operation is continuous and automatic.

To convert the machine into a heater, the thermostat located

in the ceiling of the car functions the thermostatic valve. This opens a direct connection between the hot liquor of the generator and the heating coils *S*. After throwing off the heat imparted to the liquor by the fire, the fluid is conducted directly into the refrigerating coils, where additional heat of absorption by chemical action is further generated, assisting in warming the car, and the liquor passes on to the absorber in the usual way. The working of the machine is unaltered in all of its other operating functions. When the car has risen sufficiently in temperature the thermostat closes the thermostatic valve and the machine is again a refrigerator.

While this car from a construction point of view was a success in that it stood rough usage, met all the requirements of the Master Car Builders' Association, was cheap to build and economical in operation, nevertheless it was difficult to keep the pipe joints tight and leakproof. The real cause of failure, however, was due to boil-overs or foaming as soon as the car was switched or put in motion. The author devoted much time to this feature but was never able to prevent it. Of course, as soon as this occurred the car became inoperative, as liquor passed to the condenser and no anhydrous ammonia remained to expand in the refrigerating coils.

The Dense-Air System of Car Refrigeration

In 1917 the author abandoned all ammonia processes and attempted to achieve the result by means of the dense-air process. In this he has been quite successful. Fig. 7 shows a large refrigerated motor truck equipped with a one-ton dense-air refrigerating machine and having a capacity of 30,000 lb. of dressed beef at a load. The temperature maintained is 36 deg. on a 90-deg. day. A fleet of these trucks have been in continuous service for four years in the stockyards district of Chicago, handling traffic in a radius of 24 miles.

Fig. 5 Construction of Generator of Fig. 2

Fig. 8 shows diagrammatically the process as used on two of these trucks. The plant has a refrigerating capacity of 1000 lb. Its source of energy is a gasoline engine and the refrigerating medium is the air. With this combination the only operating supplies necessary are gasoline and oil. The refrigerating mechanism is located in a space occupying 2 ft. of the length of the body on the front end, leaving a receiving chamber for perishable goods 23 ft. 6 in. long, 7 ft. 4 in. wide, and 6 ft. 2 in. high. The refrigerating coils are located in the roof of the car and are fastened to the steel-plate and angle-iron carlines, which makes it possible to swing carcasses from the coils by meat hooks. The refrigerating machine is adjusted thermostatically to maintain the temperature of 36 deg. fahr. It can also be adjusted to reasonably lower room temperatures if desired, it being possible to carry the expanded air temperature of the refrigerating medium to 30 deg. below zero.

The Refrigerating Machine. The dense-air process is based upon the fact that a perfect gas under pressure, expanding adiabatically and performing external work will suffer a drop in temperature proportional to the mechanical energy produced. Its fundamental advantages lie in these characteristics: There is an unlimited supply of the agent everywhere, as air is the medium; it is readily dried by the use of deliquescent salts, it is innoxious, non-poisonous, and its explosive force lies only in its expansibility under pressure; a leak may be readily sealed and the air, once dried, becomes a perfect medium of refrigeration at temperatures much lower than is possible with any agent except CO_2.

The refrigerating unit consists of a compressor employing two cylinders (5 in. bore by 5 in. stroke), and an integral expander consisting of two cylinder ($4^3/_8$ in. bore by 5 in. stroke), both sets of cylinders operating from the same crankshaft. The unique feature of this design lies in the valve mechanism and means for controlling the expander unit. The exhaust valve is a rotary valve functioning both cylinders. The inlet valves are controlled and timed by a compound rotary cam whose length is adjustable by thermostatic control, thus making it possible to alter and control by thermostat the ratio of expansion, and therefore the resultant temperature. Castor oil is used as a lubricant in both the compressor and expander sides and the oiling system is in itself a closed cycle. The expander mechanism is oiled from the oil separator in the exhaust from the compressor and fed under pressure of the high side to the cams, valve mechanism and pistons of the expander. The compressor pistons are lubricated by splash from the crankcase and an oil separator in the low side returns the oil to the crankcase.

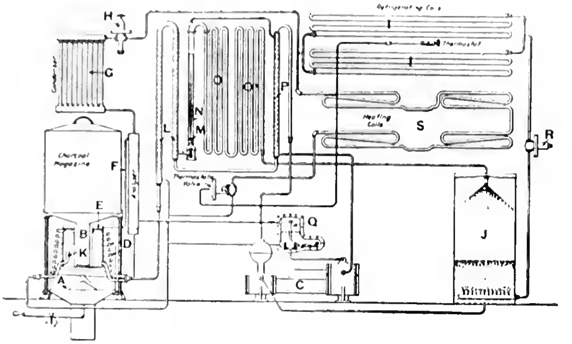

Fig. 6 Diagrammatic Plan of Car-Refrigerating System Shown in Figs. 2–5

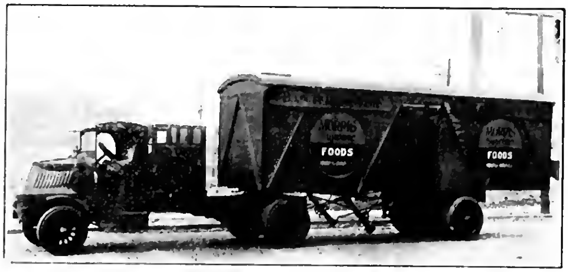

Fig. 7 Large Refrigerated Motor Truck Equipped with a One-Ton Dense-Air Refrigerating Machine

In operation the machine require $1^3/_4$ hp. which is furnished by an air-cooled engine of the Henderson motorcycle type. The engine also drives an exhaust fan of approximately 4000 cu. ft. capacity which produces a rapid flow of air across the compressed-air cooler, the compressor cylinders and gasoline engine cylinders. Proper ducts are provided to connect the various members to be cooled.

The Thermodynamic Cycle. In order to illustrate the system

and to set forth the simplicity of the refrigerating process and the incidental mechanism, attention is again called to Fig. 8 in which *A* is the refrigerating unit, *B* the gasoline engine which supplies the power, *C* the compressed-air cooler and *D* the refrigerating coils.

The device is primed by the use of the hand pump *E* connected with the drier *F*, operation of the hand pump being continued until the gage indicates the density required, as the capacity of the machine depends upon the densities of the two sides, regardless of the ration of expansion. Priming, therefore, is necessary to increase the relative capacity of the device.

In operation the compressor cylinders *G* take air through their pistons from the crankcase and discharge into the cooler *C* first through the oil separator *H*, thence through the drier *F* which removes the entrained moisture, converting the hydrous content into a fixed brine and allowing the anhydrous air to pass on to the cooler *C* where the thermal coefficient of the mechanical energy performed and the specific heat due to change in volume are removed, the cooler serving to bring the temperature of the compressed air down to a point approximately 27 deg. higher than the weather temperature of the day.

The compressed air which has been cooled now passes through the secondary drier *J* to the expander, the secondary drier serving as a precautionary device to remove any moisture which may have passed the drier *F* because of high temperature at that point. In the expander *K* the air is expanded adiabatically at the ratio of expansion determined by the position of the control piston in the cylinder *L*, which is in turn controlled by the thermostat *M*. The expanded air, of extremely low temperature, is carried to the oil separator *N* in which any oil is removed before it may enter the refrigerating coils *D*, as oil in the coils produces a decided loss in efficiency. The oil extracted in the separator *N* is returned to the return pipe from the refrigerating coils *D* by a crossover *O*, both oil and air being finally returned to the crankcase from which the compressor cylinders take their supply.

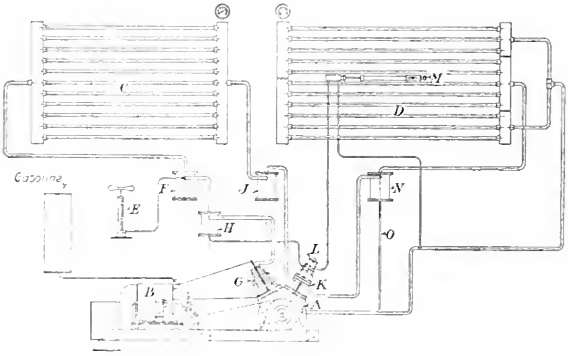

Fig. 8 Diagram Showing Process Employed on Motor Truck of Fig. 7

The thermostatic control of the ratio of expansion is accomplished by means of a piston whose position determines the length of the cam face, which in turn determines the proportionate time of opening and closing the inlet valves, and therefore the ratio of expansion. The position of the control piston is determined thermostatically by a leak-off connected with the thermostat, by which high-pressure air is allowed to escape to the low-pressure side and move the piston proportionately to its rate of escape.

In a device having extremes of temperature such as the one under consideration it is highly important that lubrication be effective and automatic. Castor oil is used because of the fact that its viscosity is not greatly affected by either the high temperature of the compressor or the extremely low temperature of the expander. The compressor cylinders take their air from the crankcase and lubrication of the compressor cylinders is effected by the splash of the crank. It follows that a comparatively large amount of oil is carried with the air into the compressor cylinders, where not only the cylinders but the valves and valve mechanism are amply lubricated. This oil is separated from the compressed air by the separator *H*, and being under the pressure of the high side is fed through a tube to the cam pocket and valve head of the expander mechanism. This constitutes a crossover for the oil. Some portion escapes around the pistons into the crankcase. The remainder is carried with the expanded air to the separator *N* where it is removed centrifugally and by-passed and returned through the tube *O*.

The Ethyl Chloride System

In addition to the systems described there is another, of the compression type, using ethyl chloride as the medium. Ethyl chloride boils at 54.5 deg. fahr. and liquefies at the low pressure of 15 lb., with condenser water at 65 deg. fahr. Its critical temperature is 365 deg. fahr., which is sufficiently high to preclude the danger of generating permanent gases. Being a neutral gas, it is possible to use thin seamless drawn copper tubes, and the joints may be soldered if desired.

As the boiling point of ethyl chloride is so low, a partial vacuum is necessary on the low side of the machine to produce the required temperature in the car. The medium is handled by a valveless rotary compressor.

The machinery is located in the end of the car and the method of operation is as follows: The medium is evaporated in the refrigerator pipes in the refrigerating compartment. The gas is then drawn to the compressor and forced into the condenser where it is liquefied. The condenser consists of a series of copper tubes placed vertically in the compartment with the compressor. The heat of compression is removed by means of a small spray of water fed to the top of the condenser, and this water is cooled by a fan so arranged that the current of air is distributed equally over the entire surface of the condenser. The power to drive this mechanism is taken from the axle of the car by means of a belt and countershaft below the compressor. Between the countershaft and the truck axle are interposed two idler pulleys upon a common guide, these pulleys being held together by springs and placed upon a guide in order that they may operate in either direction. The arrangement is such that in whichever direction the car is running the machine automatically takes up its refrigerating work. The water for cooling the condenser is carried in a tank underneath the car, from which it is pumped by a small rotary pump attached to the main shaft of the compressor. An oil engine is provided for the purpose of continuing the operation of refrigeration when the car is standing still, thus making it possible to set the car out of the train when necessary. The water for cooling the cylinder of the engine is carried in a small tank on the roof of the car.

Conclusion

As stated at the beginning of the paper and for the reasons there mentioned, it will be some time before mechanical refrigeration will be adopted on American railway cars. However, the author believes that it can be accomplished by equipping refrigerator cars with a thermosiphon system and providing a tank in the roof of the car with two compartments, one for receiving ice from regular icing stations and the other for holding a weak brine solution into which is submerged a refrigerating coil; the source of energy for cooling this brine to come from a central refrigerating-plant car carried in the train and having a capacity sufficient to refrigerate ten cars. The brine cooled in this central car would be pumped under a pressure of two or three pounds to the refrigerating coils in the various refrigerator cars, and even remove the latent heat of the brine in the tanks, if necessary, thus freezing it, thereby storing refrigerating work to be used if the car should be set out; or if the car is to be used in traffic where it is not operated from the central-plant car, then, as previously mentioned, it may be iced in the usual way, and by means of the thermosiphon system a rapid automatic circulation of the secondary refrigerating coils will take place whether the car is standing or in motion. It should be possible to store enough latent-heat energy to operate one of these cars at least 72 hours without re-icing or reconnection to the central-plant car.

This central-plant car should have installed within it a dense-air refrigerating machine of 30 tons refrigerating capacity for a ten-car unit. This machine may be driven by any of the standard forms of gas or oil engines, preferably of the Diesel type, and the entire operation can be so designed that no water need be provided to carry away the heat of compression.

The Helicopter and the Variable Pitch Propeller

Notes on Some of the Problems That Are Involved and the Present Situation of Development, Particularly in the United States

THE helicopter differs from the aeroplane in that it obtains its lift directly from the propellers and not through a component of resistance of the air acting on planes inclined at an angle to the direction of the motion of the machine.

The helicopter idea is at least as old as, if not older than, that of the aeroplane, and toy helicopters flew long before Langley and the Wright brothers. The fact that the aeroplane reached practical developments long before the helicopter is, however, due to the much greater difficulty of the solution of the latter problem.

The immediate advantage of the helicopter over the aeroplane is uncertain, depending in the end on its development. Its most important apparent advantage is its ability to rise vertically from a standing start and to hover over a given spot. On the other hand, at least as far as the helicopter has been developed to date, it would appear that its ability to maintain itself in the air is entirely dependent on the engine, and should the latter stop, the helicopter would come down like a stone. Commander J. C. Hunsaker, Aircraft Division, U. S. Navy, was asked whether he considered the present aircraft engine sufficiently reliable for the hazardous service of helicopter flying and he emphatically stated that he did not. We shall see later the ways by which it is attempted to increase the safety of the helicopter in this respect.

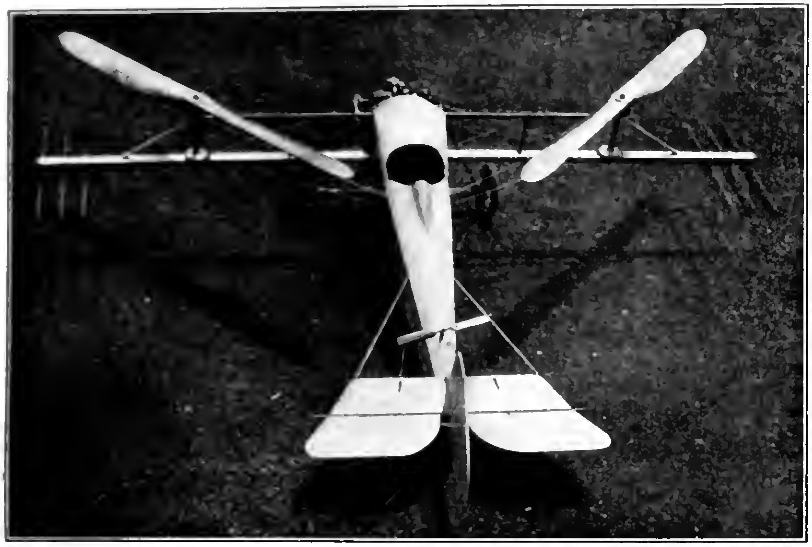

Fig. 1 The Berliner Helicopter

The Four Helicopter Problems

The riddle of the helicopter may be considered as comprising four different problems. The first is that of getting off the ground. This is the simplest and easiest part. With modern large propellers a lift of 15 lb. per horsepower can be easily obtained and as aircraft engines weigh around 2 lb. per horsepower, there is ample margin for the weight of the structure, pilot and supplies for a flight of considerable duration.

The question of getting safely back to the ground in case of engine failure is much more difficult. An aeroplane volplanes; the conventional helicopter would drop like a stone. Several unworkable devices have been suggested, such as the use of parachutes, balloons, etc. The most promising suggestions to date appear to be the use of propellers with extremely wide blades (Damblanc, Fig. 2), the angles of which may be changed so that the propeller would spin like a windmill driven by the air pressure during the descent. With propellers of proper size and design the velocity of descent might be considerably retarded, but would still remain too high to be either safe or comfortable. Another proposal (Leinweber Brothers) involves the use of planes somewhat like those in an aeroplane built up of movable shutters affording large openings during the ascent but acting practically like aeroplane planes during the descent. Whether such a construction will prove practical with the increased weight and mechanical complications, only time will show.

The next problem is that of keeping the helicopter right side up. In the Petroczy-Karman helicopter stability is insured by tethering the helicopter to the ground by cables. This, of course, can be done only with captive helicopters. In the Leinweber helicopter the control of position is secured by varying the angle of the propeller shafts (Fig. 3) with the axis of the machine. Proper balance can undoubtedly be secured in this way, providing the methods of control are sensitive enough.

In the Berliner helicopter (Fig. 1) control is secured by the use of three movable fins under each of the propellers, movable about in the stream of air projected by the propeller. The longitudinal control is secured by the little variable pitch propeller shown in the rear of the fuselage of the machine. In the Damblanc helicopter, control is secured by varying the angle of any of the blades of either propeller independently of the rest. In this way more lift can be secured from one side of the helicopter than from the other. Here again the balance will depend on the sensitiveness of the controls and also on the natural tendency of the machine towards positive or negative stability.

If the above three problems were properly solved the helicopter would be capable of rising, hovering, and coming down. To make it a transportation device it must also become capable of horizontal travel in any desired direction. This can be obtained either by tilting the whole helicopter so that the propellers pull it both forward and upward (which is accomplished in the Berliner helicopter by the use of the little variable pitch propeller), or by the use of an auxiliary propeller for horizontal drive, or, finally, by varying the pitch of the propellers as suggested by the Leinweber Brothers.

Some Foreign Helicopters

As regards helicopters of which the development has advanced far enough to give a fair idea of their construction, it should be stated at the outset that the information available is somewhat sketchy. The designers of some of the helicopters, for example, Brennan, in England, have absolutely refused to give any information to the public. Others have permitted inspection of their machines and given information but with material reservations.

Helicopters attracted some attention of Austrian army authorities as a means of replacing captive balloons for observation purposes. Helicopters, if properly developed, might prove to be quite valuable for this purpose, since in the first place they offer a much poorer target to enemy fire, and second, have fewer vital points to be hit and are not inflammable. Because of this, during the recent war, Lieutenant Petroczy and Professor Karman were authorized to build captive helicopters, one of which was equipped with electric power and the other with two LeRhone motors. The total weight of the captive helicopter and fuel for one hour,

but not including the observer, is about 1300 kg. (2860 lb.) After about 15 successive flight tests lasting up to an hour, at wind velocities up to 8 m. (26.3 ft.) per sec., the machine had a breakdown in landing. Observations proved that in addition to the fundamental demand for ample excess of thrust, the position of the center of gravity in its relation to the plane of rotation of the propeller is of great importance.

In the Karman helicopter the propellers are superimposed.

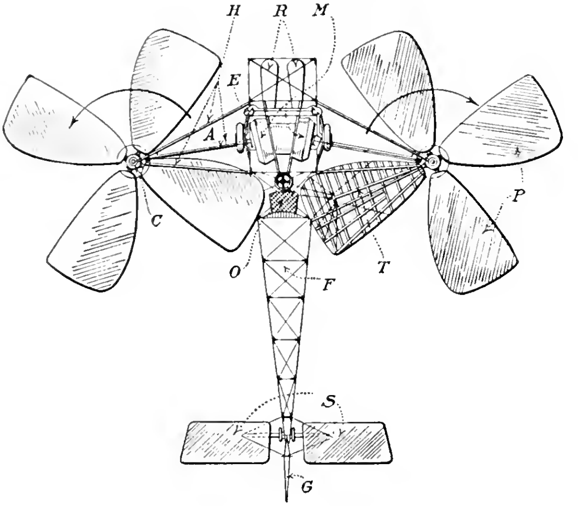

Fig. 2 The Damblanc Helicopter

In the Damblanc helicopter (France) (Fig. 2) there are two rotating wings, each formed of four blades having an area of about 5 sq. m. (53.8 ft.) In addition to this there are two stabilizing planes situated to the rear of the fuselage and controlled by a metallic cable. There is an interesting warping gear for the blades comprising articulated elbow levers acting on the blades of the wings by means of metal cables operated from a control stick. The total area of rotating wings is 40 sq. m. (131 sq. ft.) and the speed of rotation 160 r.p.m.; the weight per square meter of lifting service is 30 kg. (6.2 lb. per sq. ft.) So far as information is available only laboratory tests on this machine have been made.

In the Oemichen-Peugot machine (France) sustentation is partially derived from a hydrogen-filled balloon of fair size. It has two lifting screws driven by belts and disposed symmetrically on the upper part. The screws are each formed with two blades of a special profile, very large towards the root and very thin towards the tips. Their diameter is 21 ft. The machine is driven by a motor developing 25 hp. and weighs 740 lb. The balloon supplies a net lift of 156 lb., while the propellers have to deliver a lift of 495 lb. which is quite a good deal for a motor of 25 hp.

American Helicopter Designs

A good deal of valuable work, both development and research, is being carried on on this problem in the United States. The National Advisory Committee for Aeronautics just completed an extensive investigation of some features bearing on the helicopter problem.

Of the machines actually constructed in this country may be mentioned the helicopters built by Emil Berliner and his son Henry, in Washington, D.C., the Leinweber Brothers in Chicago, Ill., and the late Peter Cooper Hewitt, in association with Prof. F. B. Crocker. Of these the Berliner machine has two main propellers 14 ft. 10 in. in diameter running at 540 r.p.m. and an auxiliary control variable pitch propeller 3 ft. in diameter, running at 1700 to 1800 r.p.m. The machine is driven by a 110 hp. LeRhone motor and weighs complete with pilot and fuel from 1350 to 1400 lb. Henry Berliner stated that all the flights undertaken hitherto have been made at comparatively low altitudes, around 6 ft. and not to exceed 20 ft., this being done mainly in order to avoid unnecessary danger during the experimental period. He also stated that flights were made in a horizontal direction to the extent of several hundred yards.

The Leinweber Brothers machine has so far flown only in the vertical direction, being used for experimental purposes, merely as a captive helicopter. Its main features of construction appear fairly well from the photograph (Fig. 3).

It has a length 25 ft., width from propeller tip to tip 22 ft., weight 1500 lb.; uses two Gnome engines of 100 hp. each, two 10-ft. propellers and also four three-bladed propellers size 2–9 ft. 6″ on top and 2–6 ft. propellers at the bottom. In addition to that, however, the designers have developed a system of control for the propellers operating essentially in the following manner:

The active members of the control consist of two weights freely suspended as pendulums each operating a four-way valve controlling a compressed-air motor, which, in its turn, regulates the position of the shafts carrying the propeller blades. The device is somewhat similar to numerous devices used in aeroplane stabilizers where, however, their operation is apt to be considerably disturbed by centrifugal force arising when an aeroplane makes a sharp turn. When this fact was mentioned to William Leinweber he agreed with the possibility of it, but stated that the helicopter would not be supposed to take as sharp turns as an aeroplane.

An American design which attracted a good deal of attention towards the end of the war was the Hewitt-Crocker helicopter, jointly developed by the late Peter Cooper Hewitt and Prof. Francis Bacon Crocker. In this machine there are two propellers, an upper propeller revolving in a normally horizontal plane and another propeller revolving in a parallel plane 7 ft. below, each propeller being 51 ft. in diameter. The motor speed is 1400 r.p.m. and the propeller speed 100 r.p.m. which means a speed reduction of 14 to 1, this being obtained by a gear train consisting of a gear 30 in. in diameter and a pinion 2 in. in diameter. The gears are designed so as to avoid their springing out of mesh. The propeller blades of the Hewitt-Crocker helicopters have the form of aeroplane wings, not only in cross section but also in aspect ratio and other proportions. The actual section of the propeller blades is Eiffel No. 63, the thickness of which is one-tenth of the chord. The width of the blade is 30 in. and the thickness 3 in. This section and these dimensions are uniform throughout the length of a blade which is 12 ft.

For turning the machine so as to enable it to face in different directions two planes are provided, located at the extremities of two arms. These planes are capable of being tilted about a horizontal axis passing through their centers, and are located below the

Fig. 3 The Leinweber Helicopter

propeller blades so as to receive the downdraft therefrom. These planes may be used to correct any tendency of the car to rotate as a result of unequal action of the propellers.

The Variable Pitch Propeller

The development work on the helicopter is likely to lead to an intensive interest in the improvement of the variable pitch propeller. In the first place, variable pitch propellers are already used on some of the helicopters, as, for example, in the auxiliary propeller of the Berliner machine and the main propellers of the Damblane machine. In the next place, one of the main advantages of the helicopter lies in its ability to rise and descend vertically though this latter cannot yet be considered to have been accomplished to any material extent. The aeroplane of today requires, on the other hand, quite a considerable field for rising and landing, and with many designs can effect a landing only at high speeds, which makes the operation of landing to a certain extent more hazardous than average flying. If, however, really reliable and easily operated variable pitch propellers were available, the landing speeds on aeroplanes could be cut at least in half. This is exemplified by tests made at McCook Field, Air Service, War Department, with machines equipped with the Dicks steel variable pitch propeller. In landings with the propeller at constant pitch the machine came to a full stop in 625 ft. and the same machine landed in 239 ft. when the variable pitch propeller was used. In this way the aeroplane is given one more chance to defend its position against possible competition on the part of the helicopter, providing this latter should be developed to the commercial stage.

Of course, variable pitch propellers are also of great importance in connection with high altitude flying, which is likely to become a feature of aerial transportation of the future. There, the value of the variable pitch propeller lies in the following: The engine loses power with elevation, because of the reduced content of oxygen in the volume of air inducted into the cylinders, and the resultant ability to burn less fuel. In other words, the engine at higher altitudes acts as if it were partially throttled. Supercharger devices precompress the air delivered into the induction system of the engine and in this way restore the engine power delivered to the propeller. Since, however, the medium in which the propeller operates is of reduced density, the increase in speed by itself does not produce a corresponding increase in thrust, unless the propeller pitch is varied. Because of this the variable pitch propeller becomes a natural adjunct to the supercharged aeroplane engine.

The problem of the variable pitch propeller is quite simple at first glance, it being only necessary to provide some kind of a gear device to turn the blades about their longitudinal axis. The difficulty of the problem lies, however, in the fact that in a variable pitch propeller, the blades must be separate from the hub. At the same time, the stresses induced by centrifugal forces in the propeller are so high that it becomes extremely difficult to secure a method of connection between the propeller hub and the blades that could withstand these stresses. During the war Mr. Hart of California developed a wooden blade propeller having the variable pitch feature. This propeller was taken over by the Air Service, War Department, and a great deal of experimental Work and design was applied to it at McCook Field with what are said to be highly gratifying results.

Of late an all-metal variable pitch propeller has been developed, a problem of considerable difficulty, as it was believed that structures operating under the conditions of aeroplane propellers and made up of steel would be subject to crystallization of the metal and subsequent failure.

The Dicks propeller developed by Thomas A. Dicks of Pittsburgh is shown in Figs. 4 and 5 as mounted on an aeroplane at McCook Field. It is said to be the only variable pitch propeller actually operated on the 12-cylinder Liberty motor. The blades of the Dicks propeller are machined out of a special alloy steel so as to fit over a taper mandrel. A series of specially designed reamers are used to give each section the exact dimensions. The blade is then compressed to size over a series of mandrels. The gear for turning the blades and thus varying the pitch is shown in the illustration. An interesting arrangement for holding the blades in the hub is used, not subject to publication at the present time.

In flight tests on a DH plane with Liberty motor, the same speed was developed with the variable pitch steel propeller as with the permanent pitch wooden propeller, but the ground run on landing was cut practically in half. The Dicks propeller is somewhat heavier than the standard wooden propeller, which, under certain conditions, may prove to be a handicap by displacing the center of gravity too far forward. If it should prove to be possible to use lighter alloys, such as duralumin, for the blades, instead of steel as at present, not only the weight of the unit but the centrifugal stresses produced by the blades on the hubs and connections would be materially reduced.

A special system of controls has been developed for this propeller, as well as means for regulating the carburetor throttle in conjunction with the variations of the propeller pitch. These cannot be described at the present time.

Fig. 4 Dicks Variable Pitch Steel Propeller

Development Problems of the Helicopter

Coming back to the question as to the probable field of application of helicopters, one must start with a clear understanding that any prediction as to this must be made dependent on the development of the helicopter. Thus, for example, the question of safety of flight will play an important part, as well as the ability of the machine to land on extremely restricted grounds. This latter, together with the ability of the helicopter to hover, might make it extremely valuable for military purposes for operation in connection with the Navy, as well as for commercial purposes, by enabling the helicopters to act as connecting links between ships at sea, a service which aeroplanes tried to perform, but for which they have not hitherto proved entirely suitable.

On the other hand, however, engine failure, as has been stated above, would leave the helicopter powerless against the action of gravity. There is, of course, a simple remedy to meet this situation applicable, however, only to large machines, and that is, to use more than one engine. Thus, for example, the Leinweber Brothers state that they are designing a helicopter that would use 12 engines, while Professor Crocker is willing to compromise

on the more modest number of four engines. There are good reasons to believe that helicopters if they become at all available in any form similar to that of the machines now being built would be primarily a large size machine of a type where at least two, probably four, engines might be legitimately used.

Whatever may be the development of the helicopter, there is no doubt as to its value in giving us a better understanding of aerodynamic phenomena, and, in particular, of the operation of large-diameter comparatively-slow-revolution propellers.

In this connection, Edward P. Warner, of the National Advisory Committee for Aeronautics, points out as a curious fact that whereas the aeroplane has been developed almost entirely by young men not previously noted as inventors, engineers, or scientists, the fortunes of the helicopter have been more in the hands of those with reputations previously acquired in other fields. Mr. Edison has long been a believer in the future of the helicopter as the best means of air transportation and some of the important contributions to helicopter design and invention in America have been made by the late Peter Cooper Hewitt, the inventor of the mercury arc light, and by Doctor Berliner, originally responsible for the disc talking machine. In England, important work is being done by Brennan, known as the inventor of the monorail railroad. This may perhaps be explained to a certain extent by assuming that the majority of men of achievement in the nineteenth century "knew" that aeroplane flight was impossible and therefore did not bother with it, leaving the field to visionaries like Santos Dumont and the Wright brothers. There is no question today that sooner or later a workable helicopter will be built and that it is merely a matter of design, additional information and perhaps a leaven of mechanical genius that are necessary to solve the problem, and the problem itself is big enough to be attractive to men who have already won their spurs in other fields of achievement.

Fig. 5 The Dicks Variable Pitch Propeller Partly Showing External Gear for Moving Blades

There are three sets of problems that confront the designers of helicopters of the future. The first are of a purely mechanical character. Variable pitch propellers, method of installing and holding large propellers, layout of the helicopter frame subject to heavy stresses, and yet so different from the aeroplane frame, and the thousand and one details involved in this novel structure will tax the mechanical skill of the designer. As in the case of the aeroplane, this is going to be a matter of slow development, the designers learning by previous failures, and while a great amount of ingenuity will be needed, there does not seem to be anything that would be impossible of solution.

The next great problem before the designers of the helicopter of the future will be to secure the scientific information necessary. It is not so much the genius of aeronautical engineers that made the present plane so safe, efficient and powerful, as compared with the flimsy machines of 1908 and 1909 but the immense amount of aerodynamical information gathered in such laboratories as the Eiffel, National Physical at Teddington and numerous wind tunnels in America. Some of this information will of course prove applicable to helicopter design but the conditions of operation of the helicopter and the elements of its construction are so different from those incorporated in aeroplanes that a vast amount of additional information will be needed. Thus for example, we have learned in the last ten years from numberless tests on the stand, in the wind tunnels, and in actual flight a good deal about the laws governing the performance of comparatively small high-speed permanent pitch propellers, but we have only scant and uncertain knowledge as to the operation of large low-speed propellers and still less as to the effect of slight variations of pitch under different conditions of operation.

It is a fortunate matter as far as the United States is concerned that we have in this country at present research facilities that can hardly be matched by any other country in the world. The wind tunnels at Massachusetts Institute of Technology, Langley Field, McCook Field, Leland Stanford, Jr. University, not to mention smaller institutions, are excellently equipped, and what is more important manned by engineering staffs who have already shown their ability to carry on difficult path-bearing research in a highly skilled manner. In the development of aeronautical instruments and methods of investigation the United States probably leads the world. Just as an instance might be mentioned the fact that under the auspices of the National Advisory Committee for Aeronautics there have been developed recently methods for determining the pressure on every part of an aeroplane in actual flight which will rapidly eliminate the great uncertainty still prevailing as to this important factor.

The development of the helicopter is also apt to bring about changes in engine design. Most of our aeroplane engine design is still under the influence of war conditions. For military purposes single machines of maximum output for a given plan are preferable to multiple units because while single machines carry a lower general factor of safety they have a higher military factor of safety, the idea being that if one of two machines fails the flyer under actual conditions would still be able to safely reach the ground with the other engine. Under war conditions, however, the failure of a single engine would reduce the safety of the plane so as to place the flyer at the mercy of his faster adversary.

Helicopter conditions of operation from the engine point of view are, however, vastly different. As far as one can see now the safety of helicopter flight will depend on engine performace although of course unforseen developments in design can meet these conditions in a manner of which we know nothing about today. As far as we can see now, however, if the engine power of the helicopter should stop the machine would come down to the ground faster than would be desired from the point of view of at least comfort if not safety of the flyers. It has been suggested already that this difficulty might be at least partially solved by using multiple units, e.g., by Professor Francis Bacon Crocker who suggested the use of four engines.

It is an interesting fact that while important progress has been made in the design of large aeroplane engines, the field of smaller engines has been comparatively neglected and it is rather significant that practically all experimenters with helicopters are using engines dating to the early days of the war, the favorite in America being the LeRhone 110-hp. rotary.

If multiple units are to be used on helicopters these units will be comparatively small which will mean a demand for small, light and yet efficient units. Some work in this direction, called forth however by a different set of conditions, is being done already. Small engines with an output of not to exceed 60 hp. are being vigorously developed in Germany, one having been placed on the market last spring by the Siemens-Halske Company. The interest of the Germans in small engines is due to the fact that for the next two years at least, beginning with May, 1922, no civilian machines will be permitted to fly in Germany under the Treaty of Versailles if powered with more than 60 hp.

Acid-Resisting Metals and Alloys

An Account of Research Work Carried Out on Various Non-Ferrous Metals and Alloys, with Especial Reference to Their Use in the Manufacture of Mine Pumps and Chemical Apparatus

By GEORGE A. DRYSDALE,[1] INDIANAPOLIS, IND.

FOR many years past, there has been a great demand for true acid-resisting metals, more especially in the chemical and coal-mining industries. In fact, their production has become one of the great metallurgical problems of the day, for up to the present time no metal or alloy giving satisfactory results, in a broad sense of the term, has been discovered. However, a great deal of thought is now being given to the subject and much experimental work is being carried on by large manufacturing corporations interested in developing such metals. Also the United States Government, through its Bureau of Mines at Pittsburgh, Pa., is conducting a series of tests on the various known metals and alloys, to determine their acid-resisting properties.

Wherever ferrous or non-ferrous metals are used, attacking or destructive agencies in the nature of oxidation, corrosion, erosion, etc., are always present and have their detrimental effects in varying degrees. Mine pumps and apparatus for chemical industries have been made of either steel, cast iron, brass, bronze, lead, or a combination of these metals. Brass and bronze, under ordinary working conditions, have been found in the majority of cases to be superior to steel or cast iron, and lead or antimonial lead superior to brass or bronze. However, none of the metals mentioned gives satisfaction when used in the manufacture of mine pumps; in other words, none of them will stand up for a reasonable period of time against corrosion and erosion.

CONDITIONS GOVERNING THE PRODUCTION OF PRACTICABLE ACID-RESISTING METALS AND ALLOYS

It is common knowledge that an alloy containing approximately equal parts of cobalt and tin is practically acid-proof (aqua regia included), but such an alloy would be too brittle for mine pumps or chemical apparatus, and its cost would be almost prohibitive. Alloys of copper, nickel and tungsten are also highly resistant to sulphuric acid in different strengths; high-silicon ferrous alloys (14 to 15 per cent Si) are also resistant to sulphuric, nitric and other acids, but on account of their excessive hardness and brittleness their use is limited, and therefore none of them complies with the four major conditions which must be the basis of consideration in perfecting a true acid-resisting metal and placing it on a commercial basis. These conditions are:

1 The metal or alloy must be good from the foundry standpoint—a metal or a perfect alloy that gives a very dense structure, is free from a tendency toward segregation on cooling, pours well, does not excessively oxidize in melting, does not burn the sand in pouring, takes a good impression of the mold, has a normal shrinkage, and makes castings that are easily cleanable.

2 The metal or alloy must machine well and not be too hard. Some acid-resisting metals, especially ferrous, pour well but are too hard and brittle to machine, and consequently their field of usefulness is limited.

3 The metal or alloy must have certain physical properties which are under control and which enable the manufacturer to comply with any reasonable specifications that may be called for, such as degrees of toughness, malleability and strength.

4 Such a metal or alloy in the form of castings, bar stock, plates, etc., must be reasonable in price. Therefore, outside the cost of the virgin metal used for such a metal or alloy, the other three major conditions have a great deal to do with the cost of the parts made.

Three or more years ago the Midwest Engine Company requested its metallurgical department, of which the author has charge, to conduct experimental work for the purpose of developing an acid-resisting metal for use in pumps which the company supplied to coal mines in the anthracite and bituminous regions; consequently the tests dealt more especially with sulphuric acid. Heretofore most of the pumps were made of so-called acid-resisting bronzes, but their life was short, especially in certain districts where the mine water was very bad. For example, in mine waters with free acid (as sulphuric) ranging from 13.67 grains per gallon in one particular instance to 91.96 grains in another, and mineral matter from 74 grains per gallon to 479 grains, it is with apparent difficulty that these mines retain a pump in good working condition for any reasonable length of time, withstanding the action of the acid and also the erosion from mineral solids in suspension in the water. Laboratory tests were therefore started with the purpose of finding a metal or alloy that would comply with the four major conditions stated above.

Experience along these lines first taught the author that when comparative tests are run on acid-resisting metals, it is best to divide the samples into three classes, namely: rolled and drawn stock; that cast under pressure, using very heavy risers—these sometimes weighing more than the casting itself (which is expensive); and castings poured in the ordinary way or following along the lines of usual procedure in a brass foundry. This is done for the reason that widely different results are obtained both as to the acid-resisting qualities and the physical properties. As an example, an alloy well known under the trade name of monel metal may be cited. In testing out this metal in sulphuric acid of different strengths and temperatures, it was found that the degree of resistance was greater in the rolled and the cast-under-pressure stock than in the ordinary cast metal. The physical properties were high in the first and second instances, but low in the third. The average results from a number of test bars poured under pressure were as follows: Yield point, 37,000 lb. per sq. in.; ultimate tensile strength, 72,000 lb. per sq. in.; elongation in 2 in., 34 per cent; reduction in area, 32 per cent. When cast not under pressure the tensile strength was 25,750 lb., with low percentages of elongation and reduction in area. Monel metal gives the highest test results when poured under the highest pressure. This has also been noted with various other alloys, consequently it is now the practice of the company to only pay attention to the physical properties of test bars which give the true working conditions under which the castings are made. It has also been noticed that the rolled and drawn metal and that poured under pressure and with chills resist the corrosive and erosive action of mine water to a greater degree than do metals cast in the ordinary way. This is of course on account of the finer structure or closer grain in the former; in other words, when the cast metal is in the granular form, the corrosive action is much greater than when in the more dense or fibrous form of structure, where the penetration is naturally more difficult.

A very good example of the penetration and absorption of an acid solution in a coarse-grained metal, and the care which must be exercised to eliminate, before weighing, any salts or adherent acid, is a sample of an acid-resisting metal that was immersed in a concentrated solution of sulphuric acid for 500 hours. When the test was completed the sample was removed from the solution, carefully washed in the usual manner in distilled water, and weighed. The loss in corrosion was 1.460 per cent. However, within 24 hours after this weighing the dry sample showed a slight incrustation of sulphates on the surface. It was then placed in a beaker of distilled water where it remained for 24 hours to remove any remaining acid or salt formation. The water at the end of this time was distinctly acid, and when the sample was again dried and weighed the loss from the original weight was 2.003 per cent, the difference from the first weight after the test being 0.543 per cent. As this instance demonstrates, great care must be exercised to obtain a

Presented at a meeting of the Indianapolis Section of THE AMERICAN SOCIETY OF MECHANICAL ENGINEERS, Indianapolis, Ind., October, 28, 1921. Slightly abridged. All papers are subject to revision.

clean sample after tests are made, otherwise the results obtained will be incorrect. It also demonstrates the fact that this particular piece had an exceedingly open or coarse structure at the center, or perhaps some segregation.

Acid-Resisting Qualities Due Largely to Fineness of Grain

In consequence, the conclusion has been reached that the structure or grain of the metal or alloy is the major point in its acid-resisting qualities. This applies to ferrous and non-ferrous metals alike. With metals such as copper, tin, lead, zinc, nickel, antimony, etc., their structure may be referred to as dense and, in most instances, *fibrous;* while the cast alloys made up of these metals may be referred to as fine, medium or coarse *grained* in the majority of cases; and because of this coarseness of grain many acid-resisting alloys do not work out satisfactorily. It has also been found that the different alloys when poured in a chill mold resist the action of corrosion and erosion to a greater extent than when poured in a green mold; and when poured in a green-sand mold, more than in a dry mold. In the first instance the grain is finer than in the second, and in the second instance finer than in the third. As an example of the difference in their resistance to acid, in testing the metals separately, virgin copper, when placed in concentrated sulphuric acid (sp. gr. 1.84, 66 deg. B.), at room temperature, was readily attacked within 24 hours; when placed in a 30 per cent solution (sp. gr. 1.224, 26.5 deg. B.) the action in 30 days was almost negligible, and in a solution of 10 per cent sulphuric acid (sp. gr. 1.070, 9.5 deg. B.) the action in 30 days was very slight. The same conditions were found to exist with nickel, tin and antimony. Zinc was readily attacked by concentrated sulphuric acid, however, more especially so in the 30 per cent and 10 per cent solutions. When these metals are cast in different combinations, for example,

	Copper	Tin	Zinc	Lead
Standard bronze	88	10	2	..
Standard red brass	85	5	5	5
Yellow brass	59	3	38	..

also alloys with copper or nickel base plus zinc, with small percentages of iron and silicon, etc., it has been observed that within 24 hours they are readily attacked in the same strengths of acid solutions mentioned.

As another example, two samples, designated as A and B, of approximately the same weight were obtained from an acid-resisting alloy and were so machined that sample A exposed more of the outside or closer-grained part, and sample B more of the inner or coarser grain. They were then forwarded to the chemist of a mine in West Virginia, so as to enable him to test them out in the running mine water, which test is believed to be much nearer to the actual working conditions of a pump than laboratory tests. The results obtained were as follows:

	Sample A	Sample B
Loss in 14 days, per cent	1.78	3.68
Loss in 28 days, per cent	2.35	4.63

In other words, the loss from the coarser-grained sample was approximately twice that from the one of finer grain.

The company has succeeded in producing an alloy of a very dense structure, which is practically immune to the action of sulphuric acid of different strengths and temperatures; this metal has also been tested in the worst kind of mine water, with very gratifying results. Tests were made on this metal, designated as M-3, similar to the tests on the samples A and B previously mentioned, covering periods of 14 and 28 days. The loss in 14 days was 0.05 per cent, and in 28 days, 0.13 per cent. The tests are being continued for 90 days or a longer period, as long as interesting results are obtained. The alloy complies with the four major conditions mentioned earlier, with one exception. At the present time it has not been found possible to give this metal the strength necessary to withstand the ordinary wear and tear of mine pumps. Consequently it is not as yet a good commercial proposition.

In dealing with synthetic alloys a great deal of trouble has been encountered with segregation, especially in the larger castings. An example of such segregation would be, for instance, in an alloy of copper, nickel and zinc (placing it in the german silver group), which, if the casting has any free zinc segregation, is immediately attacked by sulphuric acid and in a short time becomes useless.

In dealing with metals used in mine pumps, it is found that the laboratory tests and the actual working conditions are vastly different. In the first instance there is but one destructive agency to be dealt with, namely, corrosion, while in the actual workings of a mine pump there are two, corrosion and erosion, and sometimes electrolysis. Therefore laboratory tests have a tendency to give results which cannot always be relied upon. For instance, two samples of acid-resisting metal were cut from the same piece in the same manner. Laboratory tests covered the immersion of one of these samples in the mine water received from a mine in West Virginia, the loss over a period of 90 days being 1.200 per cent. The second sample was forwarded to the mine and placed in the running water for a period of 14 days, with a resultant loss of 1.78 per cent.

Again, in the pumps made of the company's acid-resisting metal known under the trade name of Meco, it is found from experience that in pumping sulphuric acid of various strengths and temperatures the conditions are not as severe as when pumping mine water.

Tests on the Rate of Corrosion of Various Metals and Alloys

A series of tests on the rate of corrosion for a definite period of time, by weight, at room temperature, in concentrated sulphuric acid (sp. gr. 1.84), and a 10 per cent solution of the same acid (sp. gr. 1.07), on various metals and alloys, gave the results presented in Table 1. The samples were of approximately the same size and weight, about 15 grams, and the acid was renewed after every 100 hours' run.

TABLE 1 TESTS ON THE CORROSION OF VARIOUS METALS AND ALLOYS IMMERSED IN DILUTE AND CONCENTRATED SULPHURIC ACID

500 Hours in Sulphuric Acid—10 per cent Solution:

Metal or alloy	Base	% Loss	Condition of piece	Remarks
New Meco	Copper	6.851	Copper vigorously attacked	Cast, fairly dense
Meco	Copper	3.551	Copper and nickel vigorously attacked	Cast under pressure
Monel	Nickel	3.066	Copper and nickel vigorously attacked	Rolled, very fine
M-3	Lead	0.606	Copper and tin slightly attacked	Cast, medium grain
Lead	Lead	0.0317	Very slightly attacked	Cast, very dense
Lead (90%) and Antimony (10%)	Lead	0.019	Very slightly attacked	Cast
Tobin bronze	Copper	1.447	Moderately attacked	Rolled
88–10–2	Copper	2.980	Vigorously attacked	Cast, medium grain
M–3–1	Lead	0.506	Slightly attacked	Cast

500 Hours in Concentrated Sulphuric Acid:

Metal	Base	% Loss	Condition of piece	
C-New Meco	Copper	0.580	Slightly attacked	....
O-Meco	Copper	0.994	Mildly attacked	....
M-3	Lead	1.584	Moderately attacked	....
F-Monel	Nickel	1.027	Moderately attacked	....
Lead	Lead	1.104	Moderately attacked	....
Lead and Antimony	Lead	1.105	Moderately attacked	....
Tobin bronze	Copper	4.834	Vigorously attacked	....
88–10–2	Copper	4.612	Vigorously attacked	....
M–3–1	Lead	1.467	Moderately attacked	....

These figures clearly demonstrate that lead-base alloys are more resistant to dilute sulphuric-acid solutions than copper- and nickel-base alloys. The nickel-base alloy (monel) and the copper-base alloy with nickel (Meco) are more resistant to the concentrated acid than to the diluted form. Copper-base alloys with tin and zinc (88–10–2) also copper-base alloys with zinc (Tobin bronze) are readily attacked in both solutions.

An example of the very detrimental effect of a mine water on various metals and alloys follows, with the analysis of the mine water showing a trifle less than 479 grains of mineral matter and a little less than 92 grains of free acid (as sulphuric) per gallon. When placed in a ditch of this running water for varying periods the losses were as follows:

	Period of immersion, days	Loss per cent
Bronze (acid-resisting)	42	1.38
Ordinary brass	13	2.04
Monel metal	27	3.73
Bronze (acid-resisting)	14	3.89
Cast iron (acid-resisting)	7	7.45
Cast iron (acid-resisting)	14	11.26

Numerous tests have also been made with different metals and alloys to note their acid-resisting properties in solutions made up

Tests on Welded Cylinders

By E. A. Fessenden,[1] Troy, N. Y., and L. J. Bradford,[2] State College, Pa.

In order to compare the methods of constructing cylinders for handling anhydrous ammonia, four types of construction were tested, namely: Flange-steel shell, acetylene-welded longitudinal seam, concave heads forge welded to shell; seamless-pipe shell, convex head acetylene welded to shell; seamless-pipe shell, concave heads forge welded to shell; and flange-steel shell, acetylene-welded longitudinal seam, convex heads acetylene welded to shell. This paper describes the method of conducting the tests, presents the data obtained, and discusses the results.

The authors conclude that vessels having forge-welded heads are the least reliable and that burnt steel is often present in the weld. Also that the principal defects in acetylene welds are the course granular structure and the occasional porous spots and pinholes that develop with high pressures and the poor adhesion of the welding material to the original plate. Reasonable practical remedies for these defects are given.

AT THE request of a large machinery-manufacturing company, the following impartial tests on the five welded containers described below, were conducted by the authors.

The tests were carried on without interference or suggestions from outside sources, and the idea uppermost was that the results should indicate the relative merits of the containers under consideration.

The object of the tests was to compare several different methods of constructing the cylinders for handling anhydrous ammonia in refrigerating-plant practice. The cylinders tested involved the following four types of construction:

a Flange-steel shell, acetylene-welded longitudinal seam, concave heads forge welded to shell
b Seamless-pipe shell, convex heads acetylene welded to shell
c Seamless-pipe shell, concave heads forge welded to shell
d Flange-steel shell, acetylene-welded longitudinal seam, convex heads acetylene welded to shell.

All of the dished cylinder heads were hot pressed from flat disks in a large press or flanging machine manufactured by R. D. Wood & Co., Philadelphia, Pa.

Methods Used in Making Welds

In making the forge-welded heads the shell and head were heated to the welding heat in an ordinary forge fire and the welds were made by hand hammers and sledges. Fig. 1 shows the construction of one of these forge-welded heads.

The following description of the method of making a cylinder of seamless pipe will indicate the methods used for all the acetylene-welded cylinders.

A piece of seamless pipe of the required length to make the shell is cut off by an acetylene torch. The ends of this shell piece are not scarfed, the heads being welded directly to the ends as they are left by the cutting torch. The head is made of flange steel pressed into the dished shape, convex outward, commonly used for cylindrical vessels made to withstand internal pressure. The edge of the flange of the head is turned so as to make a square face and then the outer corner is beveled off to form a scarf. The shell and the head are then placed close together but not touching, the distance between the end of the shell as left by the cutting torch and the nearest edge of the scarf on the head being about $^1/_8$ in. Fig. 2 is a detail of the method of scarfing for making the joint and Fig. 3 shows a head in the process of welding.

When the torch is applied the metal of the shell and the head are first heated until they melt into a viscous fluid which flows down and closes up the gap between the two edges. Most of this material is taken from the shell, so that this melting-down process is practically equivalent to scarfing the edge previously left by the cutting torch. The metal from the welding wire is introduced not by melting it off the end of the wire and dropping it into the crevice between the parts to be welded as in a soldering operation, but by stirring the end of the welding wire in a little pool of molten material formed from the metal of the shell and head. Welds made in this manner are often called "ripple welds." Only very rarely was the hottest part of the torch flame allowed to play upon the welding wire, material from the wire being almost invariably introduced into the weld by the puddling process just outlined.

For longitudinal seams the welding operation was carried on in the same manner as that described for girth seams, the process being as follows: The plate used to form the cylindrical shell is rolled into shape so that the edges of the longitudinal joint nearly touch, the shell being laid longitudinally with the joint uppermost. The seam is then started at one end and welded for a distance of about 2 in. For the remainder of the seam the edges are spread apart and held in position by a jack. The amount of spreading is about $^1/_2$ in. to $^3/_4$ in. per ft. length of seam and thin shells are spread the most. As the welding progresses toward the end where the jack is placed, the strain on the edges is gradually reduced so as to allow the edges to be welded to approach each other. This device is used to eliminate as far as possible temperature stresses due to a high temperature of the welded seam.

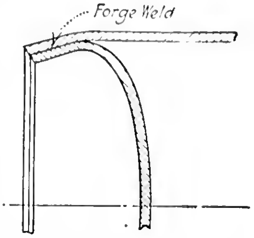

Fig. 1 Construction of Forge-Welded Head

Method of Conducting Tests

The cylinder under test was blocked up on a light truck and filled with water through openings left for the purpose. The diameter was then carefully measured at five points equally spaced along the length of the cylinder. In the cylinders made of seamless pipe these diameters were measured only horizontally as the cylinder lay in the testing rack, but in the cylinders rolled out of flange steel vertical diameters were also measured at all of the five points where the supporting blocking did not interfere with the use of calipers. Careful measurements were also made to determine the contour of each cylinder head.

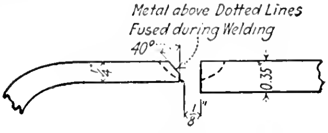

Fig. 2 Scarfing method for Making the Joint

The cylinder was then connected to a hand-operated hydraulic-testing pump, with a new and calibrated hydraulic-pressure gage in the connecting pipe line. The pressure was then gradually increased, stopping occasionally to observe carefully the condition of the cylinder and to repeat the measurements indicated above whenever it seemed desirable to record changes in the shape of the cylinder. This was continued until the cylinder failed to such an extent that the defects which developed caused leaks which made it impossible to operate the pump rapidly enough to cause further increase in the pressure.

When a cylinder had failed a number of samples were marked on the cylinder and ordered to be cut out for microscopic, metallurgical and physical tests. These samples were later shipped to the authors at State College, Pa., where they were properly prepared and examined as to their physical properties and microscopic structure. The tension tests were made by Prof. Thomas S. Patterson (Assoc-Mem. Am.Soc.M.E.), of the Department of Mechanics and Materials of Construction in the School of Engineering at The Pennsylvania State College. The microscopic and metallurgical examination was made by Prof. O. A. Knight (Mem. Am. Inst. Mining and Metallurgical Engineers, American Electrochemical Society and American Society for Steel Treating), of the Department of Metallurgy in the School of Mines of the Pennsylvania State College,

Abridgment of a paper presented at the Spring Meeting, Atlanta, Ga., May 8 to 11, 1922, of The American Society of Mechanical Engineers. The paper is an amplification of one presented by E. A. Fessenden at the May, 1921, meeting of the American Society of Refrigerating Engineers. All papers are subject to revision.

whose report is published in an appendix to the complete paper.

Test Results on Cylinder No. 1

The construction of cylinder No. 1 is shown in Fig. 4. The shell was made of flange steel, $^1/_4$ in. thick, with the longitudinal seam acetylene welded. The heads were pressed from $^1/_4$-in. flange-steel plate to a dished shape, and with a straight cylindrical flange about $2^1/_2$ in. long. The heads were inserted into the end of the shell with the convex side inward and the edge of the flange of the head forge welded to the shell, the depth of the weld being from 1 in. to $1^1/_2$ in. in the case of this cylinder. The welded ends were then crimped over to reinforce the weld as shown previously in Fig. 1.

Fig. 3 Partly Completed Acetylene Weld

The cylinder set up for testing is shown in Fig. 5. The outside diameters, measured before testing on the lines between the numbered sections, were as follows:

Between sections	1–2	2–3	3–4	4–5	5–6
Horizontal diameter, in.	12.17	12.28	12.34	12.34	12.28
Vertical diameter, in.	...	12.41	12.38	...	12.44

The following observations were made during the test at the pressure indicated:

500 lb. per sq. in. The concave head of section 1 began to reverse curvature, becoming completely convex shortly afterward.
700 lb. per sq. in. The concave head of section 6 began to reverse curvature, and very rapidly became completely convex.
950 lb. per sq. in. Leakage began through forge weld at head of section 1.
1350 lb. per sq. in. Forge weld at head of section 6 began to leak slightly.
1450 lb. per sq. in. Very bad leak through weld at head of section 6. Complete failure.

Fig. 6 shows the head of section 6 after complete failure had occurred at 1450 lb. per sq. in. internal pressure. The defective spot in the forge weld which caused final failure is on the upper left-hand quadrant.

This illustration also shows very clearly the final shape of the head after complete reversal of curvature had taken place. Accompanying the deformation of the heads the ends of the shell which were crimped over to reinforce the weld were straightened out by the bending stress on the flange of the head. As a result, after the head had completely reversed its curvature it was found that the crimping had nearly all disappeared. This obviously introduced a circumferential tensile stress upon the weld that probably contributed to the final failure. The spreading of the crimped end can be seen by a comparison of Figs. 5 and 6 and is particularly noticeable along the upper side of the shell.

During the test measurements were taken to give the contours of the heads in order to show their progressive deformation under increasing pressures. These readings were later plotted.

The factor of safety may be considered to be any one of a number of values, depending upon what is considered to be the point of failure of the cylinder. The cylinders were similar to those used by the company for holding anhydrous ammonia at an internal working pressure of 185 lb. per sq. in. gage. Using this as a basis the authors find the following factors of safety:

a If failure is considered as occurring at the first indication of deformation of the concave heads, the factor of safety is 2.70.
b If the vessel be considered to have failed as soon as the first leakage occurred, the factor of safety is 5.13.
c On the basis of the maximum pressure attained in the test with complete failure of the forge weld, the factor of safety is 7.85.

At the maximum pressure attained in the test the stress in the material forming the shell was 34,400 lb. per sq. in. of cross-section, computed on the basis of the original mean diameter of the shell. If the effective thickness of the weld is considered to be the same as that of the shell material, this value is also the stress safely withstood by the acetylene-welded longitudinal seam. On the samples cut out of this cylinder for physical tests the actual mean thickness of the weld itself was carefully measured, and for welds made in $^1/_4$-in. plate the average thickness was found to be 0.350 in. Hence the actual stress withstood by the acetylene-welded seam during the test without any sign of failure was 24,500 lb. per sq. in. This amounts to 8590 lb. per linear inch of acetylene-welded seam. The stress which caused final failure of the forge-welded seam was one-half of this or 4295 lb. per linear inch of seam.

Four samples were cut from one of the circular flange-steel blanks such as are used for making the dished heads. The results obtained when tested for tensile strength are presented in Table 1.

TABLE 1 TENSILE-STRENGTH TEST OF CYLINDER NO. 1 SPECIMENS

Sample	Dimensions, in.	Area, sq. in.	Load, lb. Yield point	Load, lb. Ultimate	Tensile strength, lb. per sq. in. Yield point	Tensile strength, lb. per sq. in. Ultimate
A	0.243×2.00	0.486	17,000	24,500	35,000	50,400
B	0.242×2.01	0.486	17,580	25,100	36,200	51,750
C	0.241×2.01	0.484	17,690	25,180	36,500	52,000
D	0.242×2.025	0.491	16,950	25,520	34,500	52,000
Average					35,425	51,538

The ultimate strength of the plate tested was thus somewhat below that specified for flange steel as set forth in the Boiler Code of The American Society of Mechanical Engineers (p. 11, Par. 28, edition of 1918), where the requirement is given as 55,000 to 65,000 lb. per sq. in. The elastic limit, or yield point, is above the requirement which states that at the yield point the stress shall have a minimum value of one-half the ultimate tensile strength, i.e., 27,500 to 32,500 lb. per sq. in. The fractures were typical flange-steel fractures showing a very fine grain. The amount of elongation and the reduction in area were not determined.

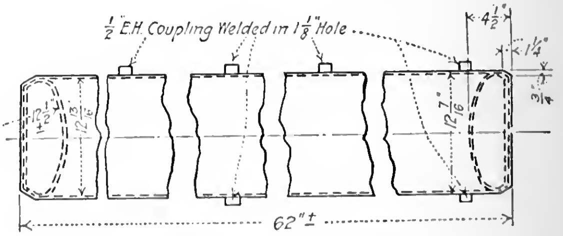

Fig. 4 Construction of Cylinder No. 1

Three samples containing sections of the acetylene-welded longitudinal seam were cut out of the cylinder and subjected to tension tests. Professor Patterson's report upon these specimens gave the results presented in Table 2.

The average ultimate strength was slightly above the value of 28,500 lb. per sq. in. specified by the Boiler Code of The American Society of Mechanical Engineers, for properly made forge welds (p. 45, Par. 186, edition of 1918). The average ultimate strength per linear inch of acetylene-welded seam was 10,097 lb.

The fractures occurred in every case through the body of the weld

TABLE 2 TENSION TEST OF CYLINDER NO. 1 SPECIMENS

Sample	Dimensions at weld, in.	Area at weld, sq. in.	Ultimate load, lb.	Tensile strength, lb. per sq. in.
E	0.362 × 1.452	0.526	13,800	26,250
F	0.333 × 1.504	0.504	13,820	32,000
G	0.334 × 1.734	0.611	17,810	29,000
	Average			29,083

itself, practically at the center line of the seam. In every case the fracture started with a crack which grew larger as the tension was increased. The final fracture did not occur suddenly and with a strong pronounced snap, as would be the case with a good flange steel, but was slow and gradual, as might be expected from a loosely knit, coarse, granular material, and was very similar to that obtained when a piece of putty is pulled in two. The elongation was not measured, but if any occurred it was very slight indeed. There was no apparent reduction of area. The fractured surfaces exhibited a very coarse granular structure quite similar to cast iron, with occasional brighter crystalline areas and flaws. There was evidence of poor adhesion between the metal of the shell and the welding material, especially along the bottom edge of the seam below the bevel of the scarf.

In Fig. 6 the horizontal lines chalked on the shell and the radial lines on the head indicate approximately the boundaries of sections later cut out for microscopic and metallurgical examination. The section containing the leak in the forge weld which caused final failure was cut into small pieces for examination and designated as specimens *PO*, *PI*, *PE* and *PZ*. These samples were cut in the order given reading from left to right in Fig. 6, *PE* being the small sample containing the crack which caused final failure. (See Appendix to complete paper for examination report.)

Cylinder No. 2

The construction of cylinder No. 2 is shown in Fig. 7. The shell was made of seamless-steel pipe approximately 0.34 in. in thickness. The heads were of dished form, with a straight cylindrical flange of the same external diameter as the shell and about 1¹/₄ in. long. The heads were welded to the shell by the acetylene torch with the convex face outward.

The cylinder was set up for testing like cylinder No. 1 and marked off into sections. Outside diameters (in inches) were measured only in the horizontal plane, before and during the test, as follows:

Between sections	1–2	2–3	3–4	4–5	5–6
Before test	12.65	12.73	12.78	12.78	12.73
At 2550 lb. per sq. in.	13.08	13.05	13.05	13.05	13.05

Fig. 5 Cylinder No. 1 Ready for Testing

The following observations were made during the test at the pressures indicated:

600 lb. per sq. in. Faint cracking sounds heard at end of section 6.

1200 lb. per sq. in. Scale cracks were observed in the forge scale on each head at the sharp bend where the flange is formed on the head. These scale cracks are shown very clearly in Fig. 8, and indicate that sufficient deformation of the convex head to crack the scale had occurred.

2000 lb. per sq. in. A very slight leak through the acetylene-welded circumferential seam joining the cylinder head to the end of section 1. This leakage was so slight, more in the nature of barely perceptible seepage, that during the entire test not more than three or four drops of water escaped.

2550 lb. per sq. in. A small leak occurred where a ½-in. extra heavy pipe coupling was acetylene welded to the shell in section 5 of the cylinder.

2600 lb. per sq. in. The leak observed at 2550 lb. per sq. in. where the coupling acetylene welded to the shell in section 5 became so large as to constitute complete failure.

The progressive approach toward the truly hemispherical head was quite apparent.

The factor of safety, computed on the same basis as for cylinder No. 1, may be taken as one of the following figures:

a If failure is considered as occurring when the first indication of deformation was observed (the cracking sounds heard near the head of section 6), the factor of safety is 3.24.

b If the vessel is considered to have failed at the first apparent leakage, the factor of safety is 10.81.

c On the basis of the maximum internal pressure reached, the factor of safety is 14.06.

Assuming the effective thickness of the weld to be the same as that of the shell material, i.e., 0.34 in., the stress in the circumferential seam at a pressure of 2000 lb. per sq. in., when the first very slight leakage was observed, was 17,700 lb. per sq. in. on the basis of the original mean diameter of the shell. This amounts to 6020 lb. per linear inch. On the same basis and the maximum pressure reached during the test, the stress on the seam was 23,000 lb. per sq. in. or 7830 lb. per linear inch of seam.

Fig. 6 Head of Cylinder No. 1 After Test, Showing Forge Weld Which Failed. Point of Failure Marked by Arrow

Two test pieces containing circumferential-seam samples were cut out for tension tests. Careful measurements of the actual mean thickness of the seam gave an average value of 0.442 in. Using this figure instead of the nominal thickness of 0.34 in., the stresses withstood by the seam during the test were as follows:

At the first slight seepage	13,620 lb. per sq. in. of seam
For the maximum pressure	17,690 lb. per sq. in. of seam

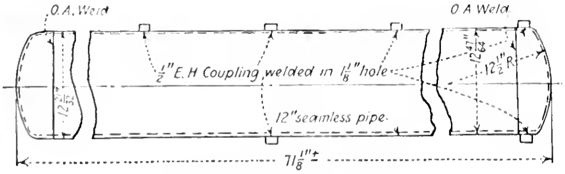

Fig. 7 Construction of Cylinder No. 2

A number of samples were cut from this cylinder for tension tests. They were located as follows:

Sample H was cut from the head of section 1. This sample may be located by reference to Fig. 8. It contained the letters GC shown at the top of the head. The very small seepage leak was also in this sample.

Sample I was similar to sample H and was cut out of the head at the end of section 6.

Sample J was a circumferential section cut out of the shell. The location was about 5 in. to the right of the coupling that caused final failure.

Fig. 8 Head of Cylinder No. 2, Showing Scale Cracks Indicating Distortion

Sample K was a longitudinal sample cut from the shell at a point about 6 in. away from the coupling that caused final failure and on the back side of the cylinder.

Professor Patterson's results for the tension tests of these samples are given in Table 3. For the shell material the elastic limit and the ultimate strength were each above the value specified for boiler-plate steel in the Boiler Code of The American Society of Mechanical Engineers. The elongation and reduction in area were not measured but were considerably less in amount than were obtained for the flange steel used for the heads in the tests described in connection with cylinder No. 1. The fractures were fine-grained.

TABLE 3 TENSION TEST OF CYLINDER NO. 2 SPECIMENS

Sample	Dimensions, in.	Area, sq. in	Load, lb. Yield point	Load, lb. Ultimate	Tensile strength, lb. per sq. in. Yield point	Tensile strength, lb. per sq. in. Ultimate
H	0.46 ×2.38	1.094	...	28,200	...	25,820
I	0.424×2.05	0.87	...	25,850	...	29,750
	Average of acetylene-welded seams					27,785
J	0.345×1.55	0.535	27,000	35,620	50,500	66,700
K	0.341×1.51	0.515	21,000	33,310	46,700	64,700
	Average of shell material					65,700

The average ultimate strength of the acetylene-welded seams was slightly below that specified by the Boiler Code for good forge-welded joints. On the basis of the average ultimate strength of the acetylene-welded seam, it would require a load of 12,010 lb. per linear inch of seam to detach the head from the shell. The fractures of the acetylene-welded joints exhibited in general the same characteristics as were described for the acetylene-welded joints of cylinder No. 1, except that in sample H the welding material pulled away from the head, opening up the spot where the slight leakage occurred. At this point the color was somewhat darker than for the remainder of the fracture. All the indications thus point to poor adhesion at the junction of the head and the welding material, probably due to oxidation.

Cylinder No. 3

The shell was made of the same kind of seamless pipe as that used in the shell of cylinder No. 2, but about 6 ft. long. The heads were similar to those used in cylinder No. 1 and were forge welded to the shell in the same manner.

The ends of the shell were crimped over to reinforce the forge weld, and like the other two cylinders, the shell was marked off into sections. The outside diameters (in inches) of the shell measured in the horizontal plane before and during the test were:

Between sections	1–2	2–3	3–4	4–5	5–6
Before test	12.64	12.76	12.81	12.81	12.75
At 550 lb. per sq. in.	12.66	12.76	12.83	12.81	12.75
At 1300 lb. per sq. in.	12.70	12.76	12.81	12.80	12.75

The following observations were made during the test at the pressures indicated:

200 lb. per sq. in. The concave head in the end of section 1 began to show tendency to reversal of curvature, distortion beginning at a place where the head had been somewhat flattened (presumably) during the process of forge welding to the shell.

550 lb. per sq. in. The concave head in the end of section 1 completely reversed in curvature.

1000 lb. per sq. in. The concave head in the end of section 6 became convex. The distortion of the head in the end of section 1 had increased markedly.

1300 lb. per sq. in. The head at section 1 was stretching rapidly and slight leaks appeared through the forge-welded joint at both heads.

1380 lb. per sq. in. Complete failure resulted from excessive leakage through the forge weld joining the head to the shell at the end of section 1. The leakage was so great that it was not possible to increase the pressure further with the pump available.

During the test, measurements were taken to show the progressive distortion of the cylinder heads. The final shape of the head of section 1 is shown in Fig. 9, and the excessive distortion in the upper left-hand quadrant coincides in position with the flattened area previously mentioned as being present in the head before the test was started and presumably caused accidentally during the forging of the joint. The final failure of the welded joint occurred in this same quadrant at a point about 30 deg. above the horizontal diameter and on a radius through the region of most excessive distortion. This is the result that would be expected, since the greatest peeling action on the weld would occur where the distortion is the maximum.

No samples were taken from this cylinder for further tests. The failure was quite similar to that of cylinder No. 1, and there was no reason for believing that further examination of the forge weld which failed would yield results differing materially from those found for the joint in the first cylinder. There was no open crack similar to that in cylinder No. 1 but the welded joint very clearly opened up to the outer edge of the joint. The opening could be distinguished easily by the naked eye.

The factor of safety, computed on the same basis as for cylinder No. 1, may be taken as one of the following figures:

a If failure is considered as occurring when the first sign of deformation of the head of section 1 was observed, the factor of safety is 1.08.

b If the cylinder is considered to have failed at the first apparent leakage, the factor of safety is 7.03.

c On the basis of the maximum internal pressure reached during the test, the factor of safety is 7.46.

The stress withstood by the forge-welded joint was 3920 lb. per linear inch of joint on the basis of the first apparent leakage, and 4040 lb. per linear inch when the leakage became so great as to constitute complete failure.

Cylinder No. 4

The shell was made of $^1/_4$-in. flange steel rolled to an average outside diameter of approximately $12^{11}/_{16}$ in. and with the longitudinal seam acetylene welded. The shell construction was thus practically

Fig. 9 Final Shape of Head of Cylinder No. 3, Showing Forge Weld Which Failed

identical with that of cylinder No. 1. The heads were pressed out of $^1/_2$-in. flange steel, and of the same construction as those of cylinder No. 2, being acetylene welded to the shell with the convex face outward.

Like the others, this cylinder was marked off into sections and the outside diameters (in inches) of the shell measured before and during the test were as follows:

Between sections	1–2	2–3	3–4	4–5	5–6
Horizontal, before test	12.19	12.38	12.41	12.41	12.31
Vertical, before test	12.55	12.52	12.44	...	12.39
Horizontal, 800 lb. per sq. in.			12.44		..
Vertical, 800 lb. per sq. in.			12.41	...	...

The following observations were made during the test at the pressures indicated:

1000 lb. per sq. in. Scale began to crack at bend of flange in head at end of section 1.

1200 lb. per sq. in. Distortion of head at end of section 1 continued; head at end of section 6 began to show distortion.

1400 lb. per sq. in. Considerable distortion apparent in both heads. The head at the end of section 1 showed an increase in diameter in the part flanged over into cylindrical shape as indicated in Fig. 10.

1700 lb. per sq. in. Complete failure occurred suddenly by tearing the acetylene-welded longitudinal seam. Failure apparently began by the material which had been added from the welding wire tearing away from the plate for a distance of about 3 in. Then the tear extended in both directions through the body of the weld itself until the total length of the tear was about 16 in. The broken surface exhibited a very coarse granular structure. Fig. 11 shows the final fracture. The part which is thought to have failed first is below and to the right of figure 2 in the photograph. Where the tear left the weld and extended into the shell material at the left-hand end is also shown.

The factor of safety, computed on the same basis as for cylinder No. 1, may be taken as one of the following figures:

a On the basis of the first noticeable distortion of the cylinder head, the factor of safety is 5.41.

b On the basis of final complete failure, the factor of safety is 9.18.

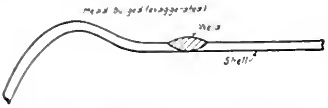

FIG. 10 DISTORTION OF HEAD AT THE END OF SECTION 1 OF CYLINDER NO. 4

For the pressure at which the acetylene-welded longitudinal seam failed and assuming the effective thickness of the weld to be the same as that of the shell material, the stress in the seam was 40,500 lb. per sq. in. Measurements on samples of the weld cut out for tests showed the average actual thickness of the weld to be 0.358 in., so that the actual ultimate strength of the weld was 28,300 lb. per sq. in., or 10,140 lb. per linear inch of welded seam.

FIG. 11 FINAL FAILURE OF ACETYLENE-WELDED LONGITUDINAL SEAM OF CYLINDER NO. 4

Three samples were cut from the longitudinal seam at a point well removed from the section which failed and subjected to tension tests by Professor Patterson. The results are given in Table 4.

TABLE 4 TENSION TEST OF CYLINDER NO. 4 SPECIMENS

Sample	Dimensions at weld, in.	Area at weld, sq. in.	Ultimate load, lb.	Tensile strength, lb. per sq. in.
L	0.336×1.919	0.645	22,710	35,200
M	0.373×1.670	0.623	17,590	28,200
N	0.365×1.924	0.693	18,170	26,200
	Average			29,870

The average ultimate strength is above the requirement of the Boiler Code of The American Society of Mechanical Engineers for good forge welds. The fractures exhibited the same characteristics as were described for the test pieces of cylinder No. 1, except that one specimen, sample L, failed by pulling the welded-in material away from the shell material instead of tearing through the center of the weld. The other two specimens showed a discolored region in the fracture that indicated the same poor knitting together at the bottom of the scarf already commented upon in the description of the fractures of weld specimens in connection with cylinder No. 1.

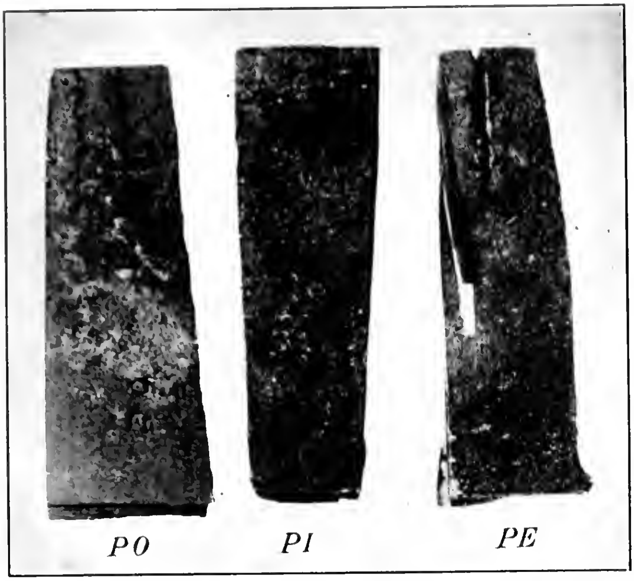

FIG. 12 CRACKS IN SPECIMENS OF CYLINDER NO. 1 REVEALED BY ETCHING AND THE CRACK IN SPECIMEN *PE* WHICH PROBABLY CAUSED FAILURE; MAGNIFICATION 1.5

The average ultimate strength of the acetylene-welded seam per linear inch of seam computed from Professor Patterson's tests, is 10,770 lb.

CYLINDER NO. 5

The shell of this cylinder was made of seamless pipe $12^3/_4$ in. in outside diameter, with pressed dished heads acetylene welded to the shell with the convex face outward, the construction being the same as that of cylinder No. 2, except that the finished cylinder was only about 3 ft. long instead of 6 ft.

A short time before finishing the tests on the first four cylinders already described, it was decided to test an additional cylinder taken out of stock. Therefore, cylinder No. 5 was chosen from a pile in the welding shop. One of the welded girth seams did not appear to be as good as those in some of the other cylinders, a second course of welding apparently having been run around the seam.

As this cylinder was tested simply as a check to compare the workmanship on stock cylinders with those submitted for test, it was not considered necessary to take detailed observations during the test. The cylinder behaved in practically the same manner as cylinder No. 2, except that no leakage through the circumferential seams was observed. Final failure occurred at a pressure of 1900 lb. per sq. in. by serious leakage through an acetylene weld securing a pipe coupling in one of the heads. The scale cracks along the bend of the flange of the head and the tendency of the head to assume a hemispherical shape were also noticeable.

On the basis of final failure and assuming that the working pressure for which the cylinder was designed was 185 lb. per sq. in. as in the other cylinders tested, the factor of safety is 10.28.

Using the same initial diameter as in cylinder No. 2 and assuming that the effective thickness of the acetylene-welded circumferential seam is the same as that of the shell material, this seam safely withstood a stress of 16,820 lb. per sq. in. of cross-section without any sign of leakage or distress. If the actual thickness of the weld is taken to be 0.442 in. as was found on carefully measured

specimens of similar welds in cylinder No. 2, the stress safely withstood was 12,930 lb. per sq. in. The stress per linear inch of seam safely withstood was 5715 lb., without any sign of leakage or distress of any kind.

Summary

Table 5 summarizes the results of the tests. It is somewhat difficult to make a comparison between the acetylene-welded and the forge-welded seams on the basis of tensile strength, because the stress on the acetylene-welded seam is a direct tension while that on the forge-welded seam is shearing. Possibly the fairest comparison is the load which the seam will carry, expressed in pounds per linear inch of seam. Table 6 gives the strength of the several joints, using the results of the tests on the five cylinders as well as those obtained by Professor Patterson. Even this is not an entirely fair comparison, because some of the acetylene-welded seams are thicker than others. The average stresses per linear inch of seam are as follows:

	At first leakage through seam, lb.	At final failure of seam, lb.
Forge-welded seams.............	3365	4168
Acetylene-welded seams..........	8080	10754

Discussion and Recommendations

In considering the results here presented it must be borne in mind constantly that the object of the investigation was to compare different methods of constructing containers for anhydrous ammonia for use in refrigerating-plant practice. Even a comparatively small ammonia leak is sufficient to make the room in which it occurs untenable. If the leak occurs in a confined space where ventilation is poor, as, for example, on shipboard, the results may be quiet serious. In boiler practice absolute tightness is not nearly so important as adequate strength against serious rupture, but it should be emphasized that in the case of containers for anhydrous ammonia, *leakage constitutes failure.*

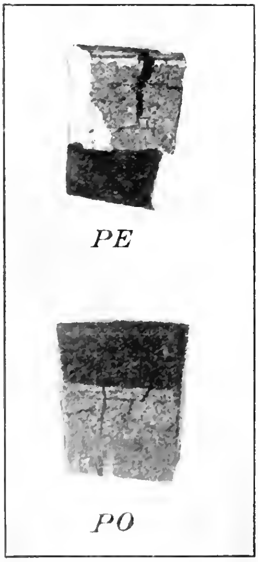

Fig. 13 End Views of Specimens *PO* and *PE*, Showing Cracks Extended Deeply into Metal; Magnification 1.5

From all of the data secured by the tests themselves and also by subsequent investigation and analysis it appears that the vessels having forge-welded heads are the least reliable. The entire circumference of the weld is likely to have incipient cracks where the union between the flange of the head and the end of the shell is imperfect. If the common shape of dished head is used it obviously must be inserted in the shell with the concave side outward in order to make a forge weld. Under the action of heavy internal pressure the curvature of the heads is reversed and this sets up a tearing or peeling action which increases the incipient flaws in the weld and leakage follows. This result is still further aggravated by the opening out of the crimped ends due to the spreading action of the head during reversal and the consequent expansion of the material just at the weld. Furthermore, it is quite likely that the dished heads are more or less distorted during the forge-welding process. Surfaces that are subjected to pressure on the convex side are in a state of unstable equilibrium and even slight initial distortion will result in excessive distortion at much lower pressures than would be carried safely. This was shown in the case of cylinder No. 3, in which one head was somewhat flattened when received at the testing floor. This head began to reverse curvature at 200 lb. per sq. in. The initial distortion undoubtedly contributed to its low resistance.

TABLE 6 STRESSES PER LINEAR INCH OF SEAMS

Cylinder No.	At first observed leakage through seam during test, lb.	At maximum pressure reached in test, lb.	At failure of joint by tension test, lb.
1 (forge-welded).....	2810	4295	....
3 (forge-welded).....	3920	4040	....
1 (acetylene-welded).	....	8500[1]	10097
2 (acetylene-welded).	6020	7830[1]	12010

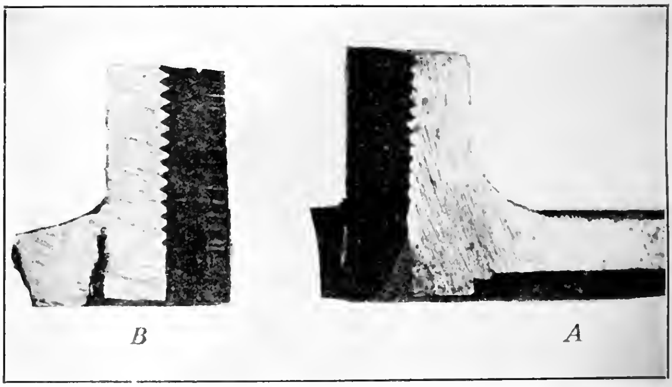

Fig. 14 Two Pipe-Coupling Specimens. *B* is the Nipple of Cylinder No. 2 Which Leaked Through the Weld. *A* is Sound Nipple Welding That Did Not Leak; Magnification 1.5

In the forge-welded specimens examined microscopically, evidence of burnt steel was found in all cases. In general, burnt steel may be expected in forge welds because the burning temperature and the welding temperature for steel are quite close together. Some time must elapse, and hence some cooling takes place, between the instant the pieces are removed from the forge and the time at which the welding actually takes place. It is essential that the pieces be at the welding temperature at the time the blows are struck. The comparatively thin pieces in question lose heat rapidly and this leads to their requiring a higher forge temperature than pieces of more compact form, thus increasing the danger of burnt steel. Burnt steel and overheated steel are very weak and brittle as compared to steel not treated so. When burnt steel is forged, cracks like those in specimen *PE* (Fig. 12) are formed. This action renders leakage under pressure and consequent failure easy.

Steam Utilization in a Modern Newsprint Mill

An Analysis of the Conditions Obtaining in a Modern Paper Mill Manufacturing Newsprint, Dealing with the Selection of a Prime Mover, Electric vs. Rope Drive for Paper Machines, the Drying of Paper, Ventilation Requirements, Etc.

By S. W. Slater[1] and J. E. A. Warner,[2] Cape Madeleine, Que., Canada

The purpose of this paper is to show the heat required in the manufacture of newsprint on a modern basis. It is, in general, a detailed study of the concrete conditions found to exist in a modern paper mill with which the authors have been associated. Other conditions found to exist in paper mills have been treated, however, with a view of showing their bearing upon the different subjects which are covered herein, and also to facilitate comparison by other mills whose installations are different from the one cited.

In general, the importance of heat conservation has not been appreciated in this industry and, in view of the national movement to conserve natural resources, all newsprint paper mills are in duty bound to study their own particular problem, so that their coal or fuel-oil requirements may be reduced to a minimum. It is hoped, therefore, that this paper may be of assistance to those who, no longer content with operating by rule of thumb, desire to analyze their heat load, in order to assist in conservation and to reduce the cost of manufacture.

A survey made as of January 1, 1922, shows that the United States and Canada have a combined daily output of about 8500 tons. The tonnage produced during the year 1921 was approximately 2,038,095 tons, and the value of this tonnage, at a representative figure of $100 a ton, would be $203,809,500.

On the basis of the familiar statement that "One ton of coal is required to produce one ton of paper," the newsprint industry has a yearly fuel demand equivalent to about 2,040,000 tons of coal. In the United States, it has been quoted as occupying sixth place in capital invested and value of product, while in horsepower installed it probably ranks fourth.

Description of Mill Investigated

The building housing the two paper machines is 288 ft. long by 88 ft. wide and has a total height of 45 ft. It is of standard brick and steel construction, with concrete floors and roof, the latter being waterproofed with tar and felt. The paper machines are carried on an operating floor which is 27 ft. from the roof. Underneath is a basement having a height of 18 ft. and its floor at grade level. Only the northeast side is exposed, other buildings adjoining the remaining side and ends. The openings in the exposed wall have a total area of 3000 sq. ft.

The greater part of the driving mechanism for this installation is located in the basement. The prime movers are steam turbines of the single-stage non-condensing type, direct-connected through flexible couplings to reduction gears, and have a rated capacity of 400 b.hp. at a speed of 2675 r.p.m. This gives a speed reduction of about 7 to 1. The turbo-gears in turn drive an English system of rope transmission, in which each section of the paper machine has its own jackshaft, carrying a cone pulley and sheaves.

By means of belts, power is transmitted from the cone pulleys on the jackshaft to the cone pulleys driving each section of the paper machine. The cone pulleys transmit through a friction clutch and herringbone gears to each of the sections. In the case of the drier sections further spur gears are used to drive from one drier to the next in the section.

The Paper Machines

The paper machines are of the Fourdrinier type, are 166 in. wide and have three presses. The drier sections consist of one fore drier, 24 in. in diameter by 162 in. face; 32 driers, 60 in. in diameter by 162 in. face; and two felt driers, one for each section, 48 in. by 162 in. All driers are of cast iron, bored on the inside, and turned and polished on the external surfaces. Each drier is equipped with a dipper, to remove the water of condensation. These machines are designed for a maximum speed of 700 ft. per min.

Newsprint consists of from 70 to 85 per cent of ground wood and the remainder sulphite pulp. After the mixture has been reduced to a consistency of about $^1/_2$ per cent, it is caused to flow onto the wire of the paper machine in amounts carefully regulated so as to finally produce finished paper weighing 32 lb. per ream of 500 sheets, size 24 by 36 in.

The web is formed by the oscillating motion of the Fourdrinier section. Water is removed through the wire, assisted by the capillary attraction of the table rolls, which also act as carriers for the wire. The suction boxes remove a large quantity of water and assist in closing the sheet. The paper then passes between the couch rolls, which press out additional moisture.

In passing through the press sections the sheet is carried on woolen felts between weighted rolls, further reducing the moisture content.

The paper is then ready to enter the driers, where water is removed from the sheet by contact with steam-heated cylinders and is carried through same on canvas felts. The last drier is equipped for cold-water circulation, so as to dampen the sheet before it passes through the calender stack for ironing and polishing, prior to cutting to specified size and winding on cores.

Heat Required for Newsprint Manufacture

In order to show more clearly the heat required for newsprint manufacture, simultaneous tests were conducted on one of the previously mentioned machines to determine the heat demand for driving, drying and ventilating.

The data pertaining to the turbine test are given in Table 1. The steam supplied to the turbine was the same as that used by the driers. In other words, the turbine water rate balanced the drier heat demand and no auxiliary live steam was required.

TABLE 1 TURBINE TEST

Initial steam:	
Pressure, lb. per sq. in. abs.	160.7
Temperature, deg. fahr.	401.3
Total heat per lb., B.t.u.	1217.3
Exhaust steam used by driers:	
Pressure, lb. per sq. in. abs	23.7
Temperature, deg. fahr.	248.1
Total heat per lb., B.t.u.	1164.7
Lb. steam per hour	16,822.00
Lb. steam per min.	280.37
B.t.u. per min. to turbine	14,747.30
Equivalent B.t.u. per b.hp. (as given by manufacturers)	44.17
B.hp. developed	334.00
Water rate, lb. per hp-hr	50.37

In selecting a suitable prime mover the governing factor is the amount of steam required for drying the paper; consequently it does not follow that the engine or turbine having the lowest water rate is the most suitable.

The water rate of the prime mover, in conjunction with the initial steam pressure and quality, must also be such as to insure approximately dry exhaust steam, at drier pressure, as it is undesirable to have steam of a high moisture or superheat content entering the driers.

Fig. 1 has been prepared to show the effect of the water rate of the turbine upon the quality of the exhaust. It will be noted that for the rate existing at the time of the test the exhaust was superheated 11 deg. fahr., and that when 45 lb. were used per b.hp. per hour the exhaust steam would be dry-saturated.

In the past it has been very difficult to obtain data showing the horsepower requirements of paper machines, but with the advent of motor drives more information is becoming available. It is impossible to give a formula that will cover all installations, for the power requirements will vary with the type and mechanical design

[2] Asst. Engr., St. Maurice Paper Co., Ltd. Assoc-Mem. Am.Soc.M.E.

Paper to be presented at the Springfield Regional Meeting of The American Society of Mechanical Engineers, Springfield, Mass., Sept. 25–27, 1922. Slightly abridged. All papers are subject to revision.

of the machine, the conditions under which it is operated and the efficiency of transmission. The following, however, is cited to show approximately the power demand of the variable-speed drive, and is based on a speed of 100 ft. per min. and 100 in. width:

1	Modern high-speed motor-driven machines, having four presses, forty 72-in. driers and operating at speeds varying between 700 and 1000 ft. per min.	25 to 30 hp.
2	Turbine-driven machines, rope-drive transmission, having three presses, thirty-two 60-in. driers, and operating at speeds of 550 to 700 ft. per min.	30 to 34 hp.
3	Engine-driven machines, Marshall drive, three presses, thirty-two 48-in. driers, and operating at speeds of from 350 to 600 ft. per min.	33 to 38 hp.

ELECTRIC DRIVES FOR PAPER MACHINES

Much attention of late has been given to electric drives for paper machines, and in some recent installations the electric energy for driving is generated by a hydroelectric plant. The steam required for the driers is then obtained from high-pressure steam reduced through a pressure-reducing valve to a lower pressure, with consequent superheat; as will be shown later, however, superheat is not suitable for use in the driers.

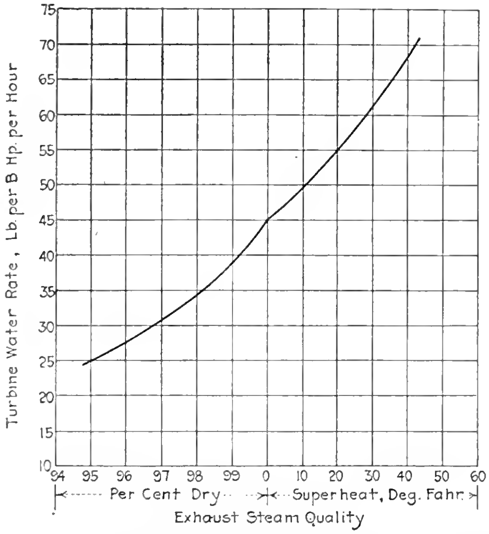

Fig. 1 Curve Showing Effect of Water Rate on Quality of Exhaust

Further, unless electrical power can be purchased at a cheap rate, it is not thought that such an installation is economical, and for the purpose of illustrating this point the following computations have been made to determine at what price electrical energy would have to be purchased to be the equivalent of steam assumed to cost $0.75 per 1000 lb.

Referring to Fig. 2, which is based on the test given in Table 1, straight line *A* (205.1 B.t.u.) represents the heat of the drier condensate, and line *C* (1217.3 B.t.u.) the total heat of one pound of steam under the conditions given. Curve *B* shows the relation between the water rate of the turbine and the heat contained in the exhaust available for drying.

AC (1012.2 B.t.u.) therefore represents the heat per pound of steam which would be available for drying if a pressure-reducing valve was used. *BC* (52.6 B.t.u.) represents the amount of heat abstracted from the initial steam in doing work in the turbine.

It will be seen that the quantity expressed by *BC* is small in comparison with that represented by *AB* (959.6 B.t.u.), and that the exhaust steam contains nearly as much heat as the initial steam.

From the preceding data and based on 7600 operating hours per year, to develop one brake horsepower-year, 20,136,000 B.t.u. are required. This is equivalent to 19,900 lb. of steam which, at an assumed cost of 75 cents per 1000 lb., makes the steam cost of a horsepower-year, approximately $15.

Assuming the efficiency of the electric drive to be 95 per cent and that of the drive described to be 75 per cent, the cost of purchased electrical power must not exceed $19 per hp. year.

This comparison does not take into consideration interest and depreciation on capital invested or the maintenance and operation costs; but as the initial cost of the electric drive is approximately two and one-half times that of a turbine rope-drive installation, it is thought, that if these costs were considered, the comparison would be favorable to the turbine rope drive.

The electrical installation, however, offers many advantages from the standpoint of operation, and with the development of high-speed machines will no doubt become the most acceptable type of drive. It is the opinion of the authors that the application of the motor drive will prove most economical when the necessary electrical power is developed by a turbo-generator, the exhaust from which would be utilized for drying the paper.

The bleeder or extraction type of turbine would have the advantage of greatest flexibility in that a minimum amount of steam would be wasted during periods of light loads, when practically no steam is required in the driers.

DRYING PAPER

In the drying of paper it is requisite that the moisture be removed gradually to prevent scorching and cockling of the sheet, and this requires a definite temperature gradient through the machine. It is also necessary that the temperature of the paper be kept within certain limits to produce a good, strong sheet.

The authors believe that the logical method to employ in these heat calculations is to base all figures on the pounds of moisture removed from the paper, instead of on the actual production. This is due to the fact that the moisture content is variable, depending upon the number and efficiency of the machine presses and the amount of moisture desired in the finished sheet.

The amount of moisture in the paper entering the drier section generally varies from 65 to 76 per cent, with an average of about 72 per cent. The amount of moisture in the finished sheet varies from 5 to 10 per cent, with an average of about 8 per cent. It is important that enough moisture remain in the finished sheet to insure proper finish and strength.

By the use of the following formula the number of pounds of moisture to be removed per pound of finished paper can be readily determined:

$$W = \frac{M_1 - M_0}{100 - M_1}$$

where W = pounds of moisture removed per pound of dried paper
M_1 = percentage of moisture in sheet entering drier section, and
M_0 = percentage of moisture in dried sheet.

It is important that as much moisture as possible be removed from the sheet before it enters the driers. It should be understood, however, that there are limitations to the amount of moisture that can be removed by mechanical means, namely, the possibility of crushing the delicate web of newsprint and the effect on the life of the press felts. Each mill, by considering the above in conjunction with the cost of steam, should determine the most efficient point of moisture removal.

In order to determine the economical life of machine clothing, in relation to steam cost for drying, a study of results obtained in several mills was made. This showed that the relation between life of felts and the percentage of moisture entering the driers followed a straight line, and that it is the combined felt-days of all the press felts which determines the moisture in the sheet entering the driers. This is a fortunate relation, in that the operating days of each of the three press felts is seldom the same at any one time.

Fig. 3 shows the relation between the combined felt-days of the three press felts and the average percentage of moisture leaving the presses for the period considered; this period being taken as one-third of the combined felt-days.

Table 2 is self-explanatory and shows the relation between combined felt-days of the three presses and the cost per day, in dollars, for steam and felts. The calculated costs do not take into account the labor and the loss of production due to changing clothing. Further, this study only applies for a particular period of fixed steam and machine-clothing costs, and should be revised as conditions change.

Some plants, thinking to economize, have tried to dispense with

drier felts. This procedure has not proved satisfactory, for the reason that intimate contact of the sheet with the drier surface is of vast importance in heat transfer. The drier felt also assists in the removal of moisture.

TABLE 2 COST OF STEAM AND FELTS

Note. 8 per cent moisture in dried paper. Steam cost assumed at $0.75 per 1000 lb. No tests are available for moisture entering driers with complete new press clothing, but from a study of results which might be expected, it is assumed that moisture entering under these conditions would be 67.2 per cent.

It has been noted that a new drier felt results in a decreased steam consumption of about 300 lb. per ton of production as compared with an old one. This is due to the fact that as the felt ages, the meshes gradually become closed.

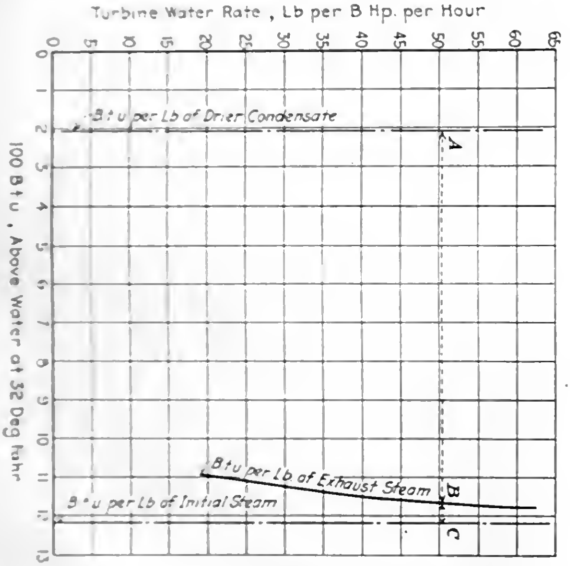

Fig. 2 Curve Showing B.t.u. per Lb. of Exhaust Steam Available for Driers

In investigating the action of the driers, that portion of them in intimate contact with the sheet has been termed the "effective" surface, while the remainder has been called "free" surface. In making comparisons between different machines the ratio of the effective surface to the total surface should always be stated.

The amount of radiating surface which does no direct useful work increases with the drier diameter, and to show the effect of diameter on effective surface, Table 3 has been prepared for a 166-in. drier with an actual working face of 156 in. This table is of interest in connection with the design of modern machines, where the high speed required must be obtained either through large diameter of driers or the greater relative speed of those of smaller diameter.

TABLE 3 EFFECT OF DRIER DIAMETER ON EFFECTIVE SURFACE

Diam. of driers, ft.	Total surface in sq. ft. (T)	Effective surface in sq. ft. (E)	Ratio $\frac{E}{T}$
4	199	104	0.523
5	257	130	0.506
6	317	156	0.492

To obtain the maximum value of the ratio E/T, the drier section should be designed so as to obtain as large an arc of contact as possible, consistent with ease of handling paper and changing drier felts. Experience shows that with an open pit under the drier section the life of the felts is materially increased, owing to the better ventilation afforded.

There are two methods in general use for removing condensation from driers, namely, siphons and revolving dippers; and opinions are at variance as to which is to be preferred. Unfortunately, neither system is capable of completely removing all the condensation, and there is always present a small depth of water in the bottom of the driers.

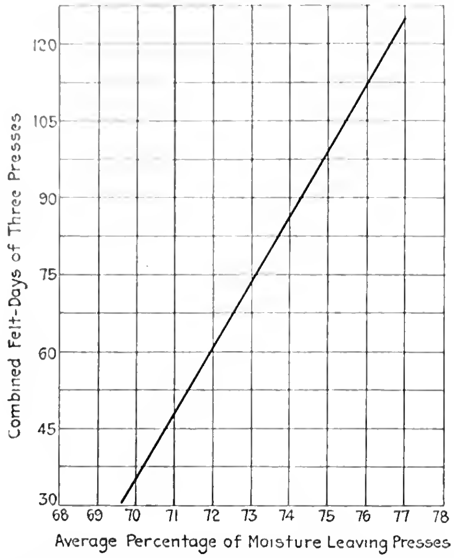

Fig. 3 Curve Showing Life of Felts in Relation to Moisture in Sheet Leaving Presses

Owing to the fact that the machines must be operated from the front side, it is the practice to locate the inlet and condensation outlet in the back side of each drier. This arrangement does not permit of a uniform or rapid circulation of steam within the driers. It is the authors' opinion that some system whereby a more rapid circulation of steam were made possible, would increase to a considerable extent the heat transfer. This could be accomplished, if it were possible to connect a number of driers in series in such a manner that the circulation of steam would follow the desired temperature gradient.

Air and other incondensable vapors, allowed to accumulate in the driers, retard heat transmission and also result in unequal temperature across the drier face. A suitable air valve should be installed to permit of rapid extraction, without allowing steam to pass.

Absolutely clean internal surfaces are required to obtain maximum heat transfer. With engine-driven machines the internal surface of the driers becomes coated with a film of oil, as oil separators do not completely remove all the lubricant from the exhaust. The turbine, however, requires no internal lubrication, and is therefore superior to a steam engine as a prime mover. The external surfaces must also be kept clean of all accumulations of dirt, grease and lint from the paper.

Superheated steam, while undoubtedly of great value for prime movers, is not desirable for drying purposes, in that it is similar in its properties to gases and parts with its heat much less readily than saturated steam. No doubt some will contend that superheated steam would tend to become saturated by contact with the

condensate, but it is thought that this would take place to a very limited extent. The amount of water in contact with the steam varying from time to time, would result in variations in temperature within the drier. Some expert papermakers contend that superheated steam produces an inferior quality of newsprint as compared with that dried by saturated steam.

The test of the drier part of the machine is given in Table 4. As shown by this table, 269,043 B.t.u. were absorbed by the driers, equivalent to 1342 B.t.u. per pound of moisture evaporated. It will be shown later that the air in passing through the drier sections absorbed 272,837 B.t.u. per min., equivalent to 1361 B.t.u. per lb. of moisture evaporated. The higher value has been used in subsequent calculations.

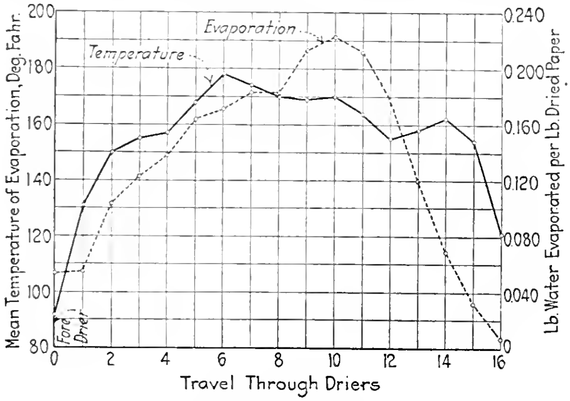

Fig. 4 Curves Showing Temperature of Evaporation and Water Evaporated in Driers

TABLE 4 TEST OF DRIER

Working width, inches, (deckle)	156
Speed, ft. per min.	650

Temperature of steam in driers, deg. fahr.	248.1
Total heat of steam supplied to driers, B.t.u. per lb.	1164.7
Heat of condensate, B.t.u. per lb.	205.1
B.t.u. absorbed by driers per lb. of steam	959.6
Lb. steam per hour to driers	16,822
Lb. steam per minute to driers	280.37
B.t.u. absorbed by driers per minute	269.043
B.t.u. absorbed by driers per lb. of moisture evaporated	1342

At the time that the test was conducted to determine the heat absorbed by the driers, data were also obtained giving the temperature gradient throughout the driers and the amount of moisture evaporated per pound of dried paper in each increment of travel, as shown by Fig. 4. By integration the theoretical amount of heat required to evaporate the moisture was determined, as shown by Table 5.

It will be noted in this table that 2.228 lb. of water were evaporated from the sheet in its complete travel, and that the theoretial heat required to do this work amounted to 2412 B.t.u. Therefore, the theoretical heat required to evaporate one pound of moisture from the sheet, under the conditions as shown, is 1083 B.t.u.

In making drier calculations it is well to remember that the only useful work performed is the evaporation of moisture from the sheet, and that therefore the theoretical amount, as determined by the conditions of the test, divided by the heat supplied, must give the efficiency of the driers.

Based on the figure of 1342 B.t.u., determined by the drier test, the efficiency is 80.7 per cent, while on the basis of 1361 B.t.u., derived from the air test, it is 79.6 per cent.

To dry paper efficiently the temperature conditions throughout the drier sections must be closely regulated. In the past, temperature control has been obtained by means of a thermostatic valve, which was dependent upon the temperature existing in one drier only. While this has given good results, the latest practice calls for sectional control, which has improved the ease of regulation.

[1] Condition of sheet entering the drier.

Without suitable experimental equipment it is very difficult to proportion the total heat transfer into that quantity absorbed by the sheet and that acquired by the surrounding air. It is thought that these quantities, once determined, would be of great assistance to the designers of paper machines, as at present, so far as the authors are aware, all calculations are based on an arbitrary figure.

Heating and Ventilating

Ventilating air supplied to a machine room may be considered as serving three distinct purposes:

1 It maintains such temperatures and humidities within the room that the operators may perform their work in comfort
2 During the period of low outside temperature it supplies sufficient heat to replace the radiation loss from the building
3 It acts as a carrier for the moisture liberated by the machine, so that this moisture is conveyed to the outside air without condensation taking place in the room.

The quantity of air supplied to a machine room depends to a large degree upon the desired machine-room temperature and humidity; and it will be found for the ordinary room, all other conditions considered, that the quantity of air insuring greatest economy is largely exceeded. This practice is only adhered to because of the resulting comfort of the operators.

Even under the best conditions the temperatures found in a machine room are quite high. Particularly is this true in the vicinity of the roof and in monitors, where the average temperature may vary from 80 to 100 deg. fahr. Further, the walls of a modern machine room contain a large glass area, resulting in a considerable heat transfer to the outside air. The radiation loss for the building under discussion may be calculated from the formula $y = 5.1 - 0.0583x$, where y is the radiation loss per pound of air in B.t.u., and x the outside or initial air temperature in deg. fahr. This formula is based on an exhaust-fan discharge of 5422 lb. of air per minute, and it shows that the radiation loss from the building makes a very appreciable demand upon the heating load for ventilation.

The air supplied for carrying away the moisture from the machine may be considered as ventilating the machine, apart from the ventilation of the room. This air, in its passage through the machine room, acquires from the wet end a certain amount of moisture, but no heat, and from the driers, both moisture and heat. It must, therefore, when expelled from the room, contain this moisture and heat, together with that which it contained whem coming in contact with the machine. Provided, therefore, that the initial and final conditions of the air are known, and also its quantity per unit of time, the amount of moisture and heat liberated by the machine can be readily calculated.

In order to determine these quantities, so that they could be used as constants in further calculations, a test, previously referred to, was conducted on a still day in summer when the machine-room windows were all open and air of a uniform temperature was supplied to the room. The advantage of making this test in summer, rather than in winter is apparent when it is considered that in winter considerable leakage takes place through openings from adjoining buildings and from the outside air, which renders it difficult to arrive at a representative value of the temperature and relative humidity of the incoming air. Also the outside tempera-

ture at the time being 83.3 deg. fahr., the radiation loss from the building could be neglected without introducing any appreciable error. The results of this test are shown in Table 6.

In making this test the discharge of hot air from each of the stacks was determined by dividing their rectangular cross-section into 24 equal divisions, and the velocity at the center of each of these divisions was determined by means of an anemometer. Wet- and dry-bulb temperatures were taken at the same time, and the discharge as computed in cubic feet per minute was converted into pounds per minute. Carrier's pyschometric charts were used to determine the moisture per pound of dry air and the total heat above 0 deg. fahr. per lb. of air. These charts were of great assistance in simplifying the calculations.

It is thus seen that the quantity of heat given up by the driers per minute as calculated on the ventilating-air basis, checked that as calculated on a steam basis within 1.5 per cent.

TABLE 6 VENTILATING-AIR TEST

	Stack No.	Dry bulb temp., deg. fahr.	Wet-bulb temp., deg. fahr.	B.t.u. per lb. of air above 0° F.	Grains moisture per lb. dry air	Lb. air per min.	Lb. dry air per min.	Lb. moisture in air	B.t.u. above 0° F. contained in air
Final air in stack	1	110	108.5	85	396	1788	1692	96	151,980
	2	118	107.0	82	360	1766	1680	86	144,812
	3	121	113.0	95	415	1868	1756	112	177,460
	Total					5422	5128	294	474,252
Initial air entering room		83.3	76	38.6	123.3	5218	5128	90	201,415
Difference in moisture and heat content between final and initial air								204	272,837

The difference between the moisture acquired by the air, 204 lb., and that liberated by the driers, 200.5 lb., can, in the opinion of the authors, be reasonably taken as the amount of moisture acquired by the ventilating air from the wet end of the machine, and in this case amounted to 3.5 lb., or less than 2 per cent of the total.

When, therefore, the machine is operating at 650 ft. per min. and 5422 lb. of air are expelled by the exhaust fans, the heat given up by the machine per minute is 272,837 B.t.u. and the moisture liberated in the same time is 204 lb.

If then values are assumed for the initial air condition, it is possible, by utilizing the above figures, to determine the final moisture and heat content of the air per pound, and by comparing the heat content of air containing this moisture with that of air containing the same moisture and at saturation, or 80 per cent relative humidity, it is possible to determine to what degree the initial outside air must be heated before entering the machine room, in order that it may function properly.

It must be borne in mind that the above statement presupposes that for low outside-air temperatures the ventilating air is preheated before admission to the machine room. Consequently, upon reaching the machine its temperature will be practically the same as applied when the test was made, and therefore the heat transfer from the driers, and the moisture absorbed from the wet end, will not, for practical purposes, be changed.

Table 7 has been prepared on a basis of initial air at 70 per cent relative humidity. From this table Fig. 5 has been plotted, which serves the purpose of estimating the machine heating load for various outside temperatures.

By referring to Fig. 5, it is seen that for the ventilation of the machine only, there is some critical temperature, in this case 66 deg. fahr., below which the outside or initial air must be preheated before coming in contact with the machine. In practice, however, this critical temperature would be slightly higher, as it is not common practice to expel the air from the machine room at a relative humidity (R. H.) as high as 100 per cent. If the final air had a relative humidity of 80 per cent, the critical temperature would be 78 deg. fahr.

By combining the quantity of heat per pound of air required by the machine with that necessary to replace the radiation loss from the building, the total heat per pound of air required for the purpose of ventilation can be determined.

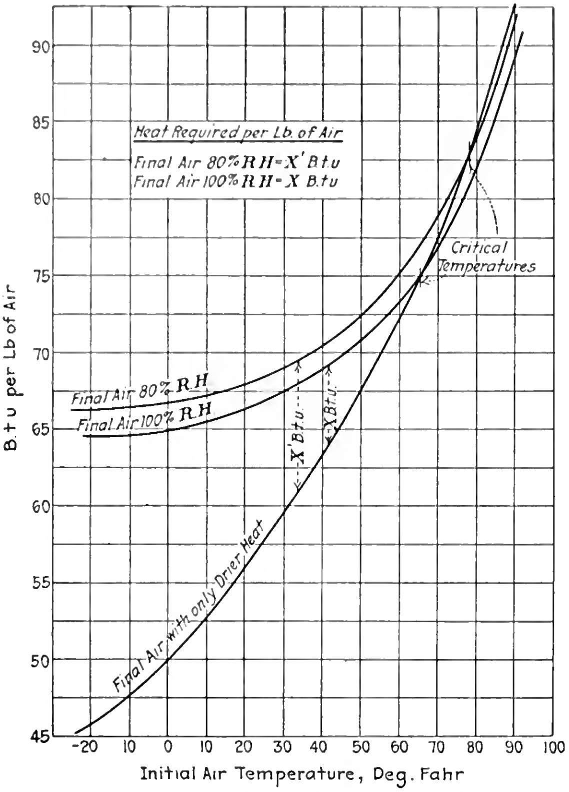

Fig. 5 Curves Showing Heat Required for Paper-Machine Ventilation

The important factor which influences the ventilating requirements of a paper mill is the amount of moisture liberated by the machine per unit of time. This in turn is dependent upon:

1 Speed of the machine
2 Moisture in sheet entering the driers
3 Moisture in sheet leaving the driers
4 Moisture absorbed from the wet end.

TABLE 7 SHOWING CHANGE IN AIR CONDITION WHILE PASSING THROUGH THE MACHINE

40	70	25.6	13.6	5218	5199	19	70965	3.5	200.5	272,837	5422	223	5199	301	343,802	63.3	69.0	70.5
50	70	37.3	17.9	5218	5190	28	93402	3.5	200.5	272,837	5422	232	5190	313	366,239	67.5	70.7	72.4
60	70	54.0	22.8	5218	5178	40	118970	3.5	200.5	272,837	5422	244	5178	330	391,807	72.2	73.3	75.2
70	70	76.0	28.3	5218	5162	56	147669	3.5	200.5	272,837	5422	260	5162	353	420,526	77.5	76.8	79.0
80	70	107.0	35.6	5218	5140	78	185761	3.5	200.5	272,837	5422	282	5140	384	458,598	84.5	82.3	84.2
90	70	149.2	44.2	5218	5110	108	230636	3.5	200.5	272,837	5422	312	5110	427	503,473	92.7	89.4	91.6

The old practice, therefore, of specifying paper-mill ventilation on a basis of so many minutes air change, without due regard to the moisture liberated, is not correct, as it is obvious that the amount of moisture liberated in two machine rooms of the same size might be entirely different.

Much of late has been written regarding the proper distribution of air in the machine room, but it is not the intention of the authors to discuss this further, except to state that, in their opinion, the greater part of the ventilating air should be delivered in the vicinity of the driers and the wet end, so that the moisture may be confined at its source. Further, that sufficient warm dry air should be supplied to the roof and all pockets, such as monitors, in order that the moisture-laden air shall not become chilled below the dewpoint, causing drip.

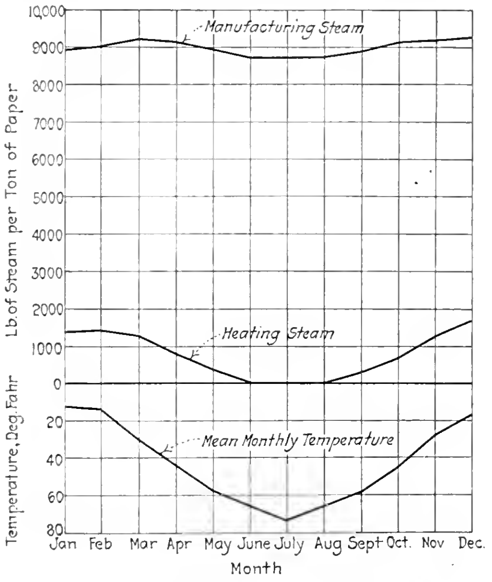

Fig. 6 Curves Showing Temperature and Steam for Manufacturing and Heating, by Months

The amount of heat lost to the process by the expelled ventilating air is in all probability the greatest unpardonable waste in the manufacture of paper.

By referring to Table 7, it can be seen that, with initial air at 10 deg. fahr. and of 70 per cent relative humidity, the total heat above zero deg. fahr. is 2.5 B.t.u. per lb., and the heat content of a pound of final air at 100 per cent relative humidity is 65.5 B.t.u. above 0 deg. fahr., the difference in the heat content per pound of air being 63 B.t.u.

Only 12.8 B.t.u. per lb., however, have to be furnished in order to preheat the incoming air, the balance of this difference being supplied by the driers. It is here that an economizer could be used to great advantage in reclaiming from the expelled air enough heat to condition the incoming air.

Owing to the high relative humidity of the outgoing air, a few degrees' drop in temperature in the economizer would be sufficient to supply heat necessary to preheat the incoming air, with the result that no live or exhaust steam would be required for ventilation.

The saving in operating cost which would result in winter from such an installation is apparent when it is considered that, for the conditions under consideration, at least 5900 lb. of dry steam, at 10 lb. per sq. in. pressure, would be required per hour for preheating the ventilating air when the outside temperature was 10 deg. fahr. and the relative humidity 70 per cent.

Fig. 6 shows for the period of one year the manufacturing and heating load in pounds of steam per ton of product, also the mean monthly temperature which prevailed. It is interesting to note the relative importance of the heating load, and it can be readily realized that the manufacturing cost could be considerably reduced if, by the installation of an economizer, this were done away with.

Conclusion

This paper does not make a complete survey of the subject under discussion, but the authors, in seeking to collect material for the subject-matter, have been impressed with the lack of detailed information which is available. It may be that some mills have studied their problems in great detail, but if so, the information is treated as strictly confidential. It can be understood that, once a paper machine is installed, the owners are reluctant to decrease production while making experimental tests. Therefore, paper-machine manufacturers are unable, in certain respects, to procure reliable operating data upon which to base their designs.

TESTS ON WELDED CYLINDERS

(Continued from page 586)

Oxide inclusions along the surfaces joined by forge welding are practically inevitable. Where an oxide inclusion exists the union between the two pieces welded together is obviously imperfect, thus weakening the weld.

If the forge-welding process is to be used it is recommended that decisive steps be taken toward much more careful temperature control.

The work also indicates clearly that the best type of vessel tested was that made up of a seamless-pipe shell with acetylene-welded dished heads, convex outward. This construction places the welds where they have to sustain a minimum stress and eliminates the danger of a failure such as occurred in the cases of cylinder No. 4.

In the five cylinders tested there were two acetylene-welded longitudinal seams and six acetylene-welded circumferential seams, a total of eight important acetylene-welded seams. The authors were able to rupture but one of these, a longitudinal seam. Very slight leakage was obtained at one other, a circumferential seam. Of the four forge-welded seams every one failed by excessive leakage at pressures considerably lower than those safely sustained by the acetylene welds.

There were a total of 28 pipe fittings acetylene-welded to the five cylinders. Leakage was observed through two of those, in each case finally resulting in failure.

The tests also indicate that the acteylene welds are likely to have occasional porous spots and that pinholes may often develop when high pressures are reached. They also indicate that the welds where fittings for pipe connections are joined to the vessel are almost as likely to cause failure as are the longitudinal and circumferential seams.

The acetylene welds also have non-metallic inclusions, but they are more globular in form than those found in the forge welds and are also scattered in all directions through the material instead of being concentrated along the contact surface. They are therefore less likely to cause leakage.

The principal defects in the acetylene welds examined seem to be the coarse granular structure and porous spots obtained and the occasional poor adhesion of the welding material to the original plate. Poor adhesion may be due to the plate cooling below a good welding temperature, or becoming oxidized along the surface before the welding material is added. These defects suggest the following possible remedies:

a The plate should be heated for as short a distance ahead of the fused-in material as possible. This should render cooling less likely and reduce the chance of oxidation.

b The work should be done as rapidly as possible in order to reduce the grain size to a minimum. As low a temperature as possible, consistent with good welding, is desirable for the same reason.

c The weld should be cooled as soon as possible after being made, in an effort to reduce the growth of ferrite crystals.

d Possibly oxide inclusions might be reduced by using a flame so adjusted as to be neutral or slightly reducing rather than oxidizing in nature. This would require some experimentation.

e Defects in welding attachment couplings to shells or heads, similar to those which caused the failure of cylinders Nos. 2 and 5 (see Fig. 14), could probably be avoided by scarfing the edge of the hole into which the coupling is set. While defects of this character can be avoided by careful workmanship, it would seem that scarfing would render the difficulty much less likely to occur. A scarfing tool similar to a pipe reamer could be devised easily.

f In the case of the samples of seams examined, poor adhesion was noticed in a number of cases, particularly at the bottom of the weld. This might be improved by scarfing both edges to be joined and carrying the bevel nearly if not quite to the bottom of the plate.

Progress in Synthetic-Gasoline Production

Particulars Regarding the Processes Employed—Results of Tests of an Improved Synthetic-Crude System—Comparative Costs of Manufacturing Gasoline by Different Processes

By DR. ROY CROSS,[1] KANSAS CITY, MO.

AT THE present time gasoline and other motor fuels have three principal sources, the chief of these being the gasoline found in natural crude petroleum, which amounts to about 70 per cent of the total production of the United States. The next most abundant source is synthetic gasoline, which supplies about 23 per cent of the total. The light gasoline obtained from natural gas amounts to about 5 per cent of the total, while coal furnishes about 2 per cent of the total in the form of benzol or naphtha.

Assuming that there may be no increase in the production of gasoline-bearing crude oil, we may consider the possible expansion in gasoline production on the basis of the present production of crude. Crude oil must first supply for other purposes about 26 per cent of its volume, consisting of lubricants (6 per cent), kerosene (10 per cent), and indispensable miscellaneous petroleum products and losses (10 per cent). With an average natural gasoline content of 20 per cent, 46 per cent of the natural constituents of crude oil is not an additional source of gasoline. Of the remainder (54 per cent), nearly 60 per cent, or 30 per cent of the original crude oil, can be made into synthetic gasoline, of which something like 5 per cent is now made. This makes a total of 25 per cent of the present crude production available for making gasoline and which is not now made use of. A sufficient amount of fuel oil still remains to take care of those industries which require fuel oil to the exclusion of coal. In other words, the possible production of gasoline with the present production of crude may be doubled without disorganizing other industrial requirements for oil.

It is quite apparent that the amount of gasoline from natural gas is limited. The supply of motor fuel from coal distillation is likewise limited by the requirements for the main products from coal. The immediate future source of gasoline, then, must come from cracking unless crude-oil production increases more rapidly.

Decomposition of Heavy Petroleums

When crude oil is subjected to ordinary distillation by fire the light products naturally present in the oil are distilled off as such up to a temperature of about 300 deg. cent. (572 deg. fahr.), comprising both the gasoline and the kerosene. Above this temperature the hydrocarbons undergo partial decomposition while distilling, with the result that some light products are produced and distilled along with the heavy products. Olefins as well as paraffin compounds of lower molecular weight than the oil being heated are formed. By vigorous firing, the entire oil residue may be distilled, leaving only a variable amount of residual carbon as a product of decomposition. The amount of carbon and gas formed by this pyrogenic decomposition is greater with the asphaltic or naphthene petroleums than with the paraffin-base petroleums.

This property of all heavy petroleums of decomposing into hydrocarbons of lower molecular weight by heating is generally known as "cracking." The chemical reactions involved in cracking are not definite. It was originally supposed that cracking involved the formation of a large amount of olefins according to the following reaction:

$$C_nH_{2n+2} = C_{n-m}H_{2(n-m)+2} + C_mH_{2m}$$

a specific illustration of which would be—

$$\text{Pentadecane} = \text{Octane} + \text{Heptylene}$$
$$C_{15}H_{32} = C_8H_{18} + C_7H_{14}$$

This reaction however, does not, accord with the facts, since gas and carbon are always formed in varying amounts. A reaction which corresponds to the yields as were found experimentally under certain conditions is the following equation:

$$2C_nH_{2n+2} = 2C_{n-m}H_{2(n-m)+2} + mCH_4 + mC$$

or as a specific illustration –

$$C_{15}H_{32} = C_8H_{18} + 7CH_4 + 7C$$
$$\text{Pentadecane} = \text{Octane} + \text{Methane} + \text{Carbon}$$

Yet under certain other conditions the amount of gas formed is very small, indicating that the following reaction was partly carried out:

$$(2m + 2)\ C_nH_{2n+2} = (2n + 2)\ C_nH_{2n+2} + 2(n-m)C$$

or as an illustration:

$$\text{Pentadecane} = \text{Octane} + \text{Carbon}$$
$$9C_{15}H_{32} = 16C_8H_{18} + 7C$$

The cracking of oil is not simply a decomposition of the hydrocarbon molecules. Both heavier and higher-boiling hydrocarbons as well as lighter and lower-boiling hydrocarbons are produced simultaneously. There must be polymerization to yield hydrocarbons of both higher boiling point and higher specific gravity. By continued cracking there may be made from water-white distillate, solid and ductile asphaltic cement of typical conchoidal fracture.

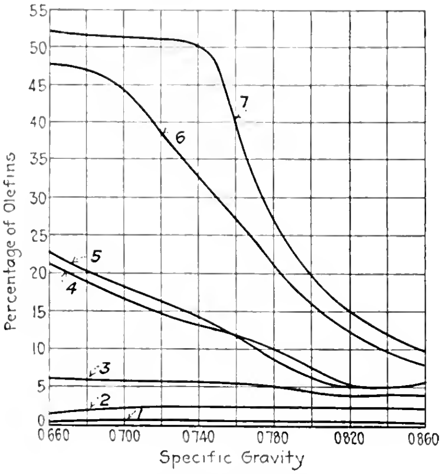

FIG. 1 Olefins or Unsaturated Compounds in Various Fractions Made by Different Processes

(1, Aluminum chloride process; 2, Burkburnett crude oil; 3, High-pressure cracking (750 lb.); 4, Burton process; 5, Low-pressure process; 6, High-temperature process; 7, High-temperature vapor-phase process.)

The gases produced by cracking likewise are not simple split-off hydrocarbons, but vary according to the method of cracking. In liquid phase cracking the chief variation is in the olefin and hydrogen content. In a general way there seems to be a tendency for low percentages of hydrogen to be associated with low percentages of olefins. A typical gas made in a Burton still gives the following percentage analysis: Methane and ethane, 82; olefins, 8.5; hydrogen, 9.5.

One of the problems in cracking is to limit the amount of hydrogen lost in the gas. This has been partly done by allowing the hydrogen to remain in contact with the cracked distillate under high pressure and at a temperature somewhat below the ordinary temperature of cracking.

Fig. 1 shows some of the relative properties of light hydrocarbons made by various processes used more or less in a commercial way for the production of gasoline from heavy oil. Gasoline made

---

[1] K. C. Testing Laboratories.

Abridgment of a paper presented at the Kansas City Regional Meeting of The American Society of Mechanical Engineers, March 6–7, 1922. All papers are subject to revision.

by the aluminum chloride process has the lowest percentage of olefins—even lower than gasoline made from natural crude oil. Gasoline made from synthetic crude comes next in order of quality. Gasoline by the pressure-distillate system is much superior to gasoline made by the high-temperature vapor-phase processes.

There are more than a thousand devices or processes relating to the production of synthetic gasoline on which patents have been issued by the United States Patent Office. Very few, however, are practical, and those that are have been made commercially successful only by extensive mechanical experiments.

Processes Employed in the Manufacture of Synthetic Gasoline

The most important matter in the commercial production of gasoline is that of cost. There are many organic substances from which gasoline may be made, including shale oil, vegetable oil and animal oil. In the laboratory it is possible to make high-grade gasoline from fish oil and the time may arrive when we shall depend upon this source for our gasoline, but at present the process is commercially impossible for obvious reasons. The most important processes for the production of gasoline commercially as well as from the standpoint of technical interest may be grouped as follows:

1 *Vapor-Phase Systems.* These are the outgrowth of the old processes for making Pintsch gas, oil gas, Blau gas and the like. They employ very high temperatures, usually above 1500 deg. fahr., and the products are of the nature of unsaturated compounds and aromatic compounds. Some of these processes use steam or natural gas mixed with the oil vapor, and various mechanical devices are employed to prevent the accumulation of carbon in the tubes. Some are operated under considerable pressure, among them being the Rittman process, which operates at a temperature of 950 deg. fahr. and upward, and the Hall (1100 deg. fahr. and upward). Others in this group are the Greenstreet and the Parker processes. By using lower temperatures, products containing a large amount of paraffin hydrocarbons or gasoline may be obtained, and some practical work is now being done in cracking oil vapors at temperatures as low as 800 to 950 deg. fahr.

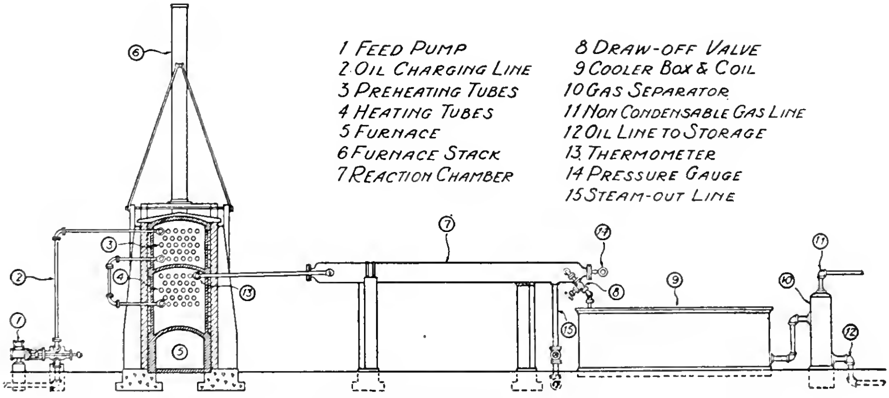

Fig. 2 Synthetic-Crude System in which the Heating and Reaction Zones Are Distinct

One of the most recent patents for cracking oil in the vapor phase provides for heating the vapor of gas oil as it comes from the crude still. The cracked vapor is then sent into a dephlegmator where the gasoline is separated and condensed. The uncracked portion is returned to the still. This method saves the fuel expense required to heat the gas oil for the second time. Electrical sources of heat have been used, but are considerably more expensive and therefore impractical. No truly catalytic processes have been commercially developed for the cracking of oil.

2 *Pressure-Distillate System.* Nearly all of the synthetic gasoline now placed on the market is made by the pressure-distillate system. The most outstanding example of it is the Burton process, the total still capacity of which in 1921 was 200,000 bbl., with an output of 2,000,000 gal. of gasoline per day. Other processes operating on this general system are the Dubbs, Coast, Jenkins, Isom, Adams, Fleming, Dewar and Redwood, Bacon and Clark, and E. M. Clark's modification of the Burton process. All of these systems operate under pressure, some with pressure on the condenser and some without, the pressure on the condenser being merely an economical means of condensing. The production of pressure distillates with this type of process is an operation necessity and refined distillate is obtained in practically none of them. The pressure distillate must be rerun and the crude benzine treated in essentially the same manner as a natural crude oil. It is in this type of process that litigation chiefly exists.

The chief disadvantages of this method of operation are the large fuel consumption, the large amount of oil under treatment at one time, the slowness of the conversion, and the expensive plant equipment.

3 *Chemical Methods.* When the heavy fractions of petroleum distillates such as kerosene, gas oil or paraffin oils are slowly heated with a small quantity of perfectly dry and active aluminum chloride, the salt dissolves, imparting a reddish to black appearance to the solution. If this dark liquor is then subjected to slow fractional distillation at a temperature below that at which aluminum chloride volatilizes, a sweet, water-white light distillate is obtained having all the properties of light high-grade gasoline that has been subjected to complete refining with sulphuric acid. Other chemicals which have essentially the same effect as aluminum chloride but to a lesser degree are anhydrous ferric chloride, tin chloride, manganic chloride, zinc chloride and phosphorus pentoxide. In the experience of the author, about 60 per cent of 55 deg. B. water-white naphtha can readily be obtained by this process with one distillation. The advantage lies in the fact that the product is completely refined. However, large quantities of hydrochloric acid gas are given off in the distillation, and the residue has very little value. The chief commercial disadvantages are the excessive cost of aluminum chloride, the loss of the fuel-oil residue, and the corrosive action of hydrochloric acid. Aluminum chloride requires the use of molecular chlorine, which cannot be made at this time at a sufficiently low price to allow its employment for competing with the straight heat processes for making gasoline.

4 *Synthetic-Crude Systems.* This method of operation presents at this time the greatest possibilities in reducing operating costs. There are three types:

a The intermittent-digestion type, in which a charge of oil is subjected to heat and pressure until reaction takes place and then is completely discharged. Representatives of this type are the Palmer and the Snelling processes. The disadvantages are the low yield per cycle, the time required for cooling, and inability to operate continuously.

b The type in which a body of oil is continuously charged and heated and more or less continuously discharged. The heating and reaction containers or zones are one and the same. The chief disadvantage is the limitation of the cycling time on account of the rapid accumulation of carbon in the reacting zone and its effect on the transfer of the furnace heat. The Hubbard patent is of this type.

c The third class is the type in which the heating and reaction zones are separate and distinct. This type is covered by one patent and provides for continuous operation and rapid conversion. Outstanding advantages are the long cycle (about one week) before cleaning—due to absence of carbon in the heating zone, the great speed of reaction (15 min.), the large ultimate yields (700 bbl. per day per unit), and the great capacity per unit of cost.

One or more units of the process may be added to any refinery merely as an adjunct, without any change in ordinary refinery

operation. With this process added a greater still capacity is necessary for a given amount of crude oil, or greater yields may be obtained with the same still capacity and with a smaller amount of crude oil available.

The scheme of operation is that shown in Fig. 2. The steam pump 1 forces the charging stock against the pressure in the apparatus through line 2, passing it from above downward through the preheating tubes 3 in the upper part of the furnace. No decomposition or cracking takes place in these upper tubes since they merely serve as fuel economizers, while the pressure in the apparatus is sufficient to maintain the oil in the liquid condition. The oil passes from these preheater tubes into the lower furnace tubes 4, starting in at the bottom. In this furnace the main absorption of heat takes place. The oil temperature is registered as it issues from the heating tubes at the point 13. The temperature of the oil and the character of the oil under treatment govern the rate of pumping. At the point 13 all of the heat has been applied to the tubes, but the oil has not yet been converted as the time element is lacking. It is therefore discharged into the reaction chamber 7, where it is held a sufficient length of time for an equilibrium to be reached between the vapor phase and the liquid phase. Ordinarily this requires less than 15 min. The discharge line through the valve 8 is set at the liquid level and perfectly controls this level without any other automatic device than an ordinary relief valve. The oil is then discharged through the cooling coil line 9 under a pressure of approximately 40 lb. and into the gas separator 10, from which the gas goes out through the line 11 and the oil is discharged through the line 12 to storage. This synthetic crude is run in the ordinary skimming plant in the usual manner.

A flow sheet for a complete gasoline plant in which all of the crude is made into gasoline and fuel oil is shown in Fig. 3. It is of course not advisable to run all of the residue into gasoline, as a point is eventually reached at which the fuel oil becomes so heavy that the gasoline yields are relatively poor.

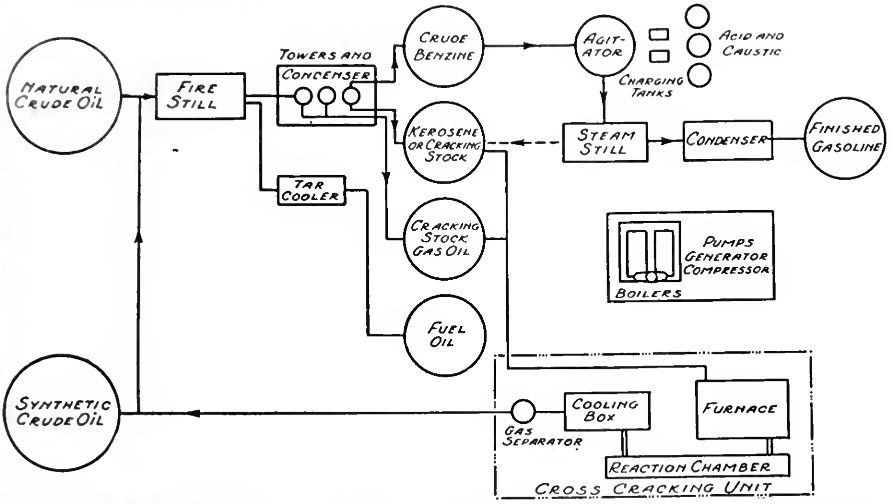

Fig. 3 Flow Sheet of Synthetic-Gasoline Plant in which All the Crude Oil is Made into Gasoline and Fuel Oil

Table 1 shows a typical run according to the synthetic crude process in which the heating zone and the reaction zone are kept separate. This plant is equipped with a forge-and-hammer-welded vapor chamber, which is being replaced in new plants now being built by reaction chambers made by the Midvale Steel & Ordnance Co. These chambers are approximately 38 in. in inside diameter and with walls 3 in. thick. With this chamber the cycle is one week, one day per week being required for cleaning. This is made possible by reason of the increased size, as the carbon accumulates in the reaction chamber and eventually fills it to such an extent that the plant must be closed down for cleaning.

TABLE 1 DATA OF RUN NO. 44 AT CRACKING PLANT NO. 1
(January 21–25, 1922)

Oil used, bbl	3030
Cracked oil delivered, bbl. (shrinkage, 4 per cent by volume)	2909
Gasoline produced, bbl.	727
Fuel used (1/8 bbl. per bbl. of gasoline produced)	91
Hours on steam	96
Hours on fire	98
Oil cracked per hour, bbl.	31.5
Fuel used per hour, bbl.	0.95
Maximum oil temperature, deg. fahr.	915
Average oil temperature, deg. fahr.	900
Maximum furnace temperature, deg. fahr.	1375
Maximum stack temperature, deg. fahr.	765
Average stack temperature, deg. fahr.	740
Pressure, lb. per sq. in.	600

The most severe strain on the apparatus is from the cooling of the reaction chamber when the plant is closed down for cleaning out the carbon. This strain tends to open welded joints but does not affect the body of the metal. All welded joints have now been eliminated with the use of the chamber forged from a single ingot.

A summary of total ultimate yields as obtained in plant No. 1 the same oil being recycled without the addition of fresh oil to the system, is as follows:

Gas oil used	10,475 bbl	= 100.0 per cent
Gasoline	6,789 bbl.	= 64.8 per cent
Fuel oil	2,600 bbl.	= 24.8 per cent
Loss	1,086 bbl.	= 10.4 per cent

As to the profits accruing from plant No. 1, the data given in Table 2 are representative of one month's operation.

Comparative Costs of Making Gasoline

While there is much variation in the absolute cost of making gasoline by any process, Table 3 outlines the comparative costs of operation of one unit of three principal systems. No satisfactory information is available for vapor-phase processes.

For convenience in estimating the cost of manufacturing gasoline the following formulas may be used as approximations. It is to be observed in these formulas that under present commercial conditions gasoline may be made by cracking methods very much more cheaply than by the skimming of natural crude.

TABLE 2 RESULTS OBTAINED FROM ONE UNIT, CRACKING-PROCESS PLANT NO. 1, FOR MONTH OF JANUARY, 1922

Charges:	
15,427 bbl. gas oil used @ $1.575	$24,297.53
420 bbl. fuel used @ $1.575	661.50
Total payroll charge for month	1,363.79
Storeroom charges for month	55.78
Fixed charge, 31 days @ $32.00	992.00
Steam, air, etc., 31 days @ $20.00	620.00
Distilling and treating 14,852 bbl. @ $0.35	5,201.70
Total charges	$33,192.30
Credits:	
4,186 bbl. gasoline @ $6.09	$25,492.74
10,622 bbl. oil returned @ $1.47	15,614.34
Total credits	$41,108.08
Less charges	$33,192.30
Estimated profit for month	$ 7,914.78

TABLE 3 COST PER BARREL OF MAKING GASOLINE BY THESE PRINCIPAL SYSTEMS

	Synthetic-crude system	Pressure-distillate system	Aluminum chloride system
Labor	$0.30	$0.90	$0.90
Materials	0.16	0.20	2.60
Fuel oil @ $1.00 per bbl.	0.10	0.40	0.40
Overhead	0.20	0.20	0.20
Fixed charges	0.25	0.75	0.60
Rerunning	1.20	1.20	0.00
Gas oil equivalent to converted gasoline	1.25	1.25	1.25
Refining loss	0.20	0.20	0.20
Degrading of gas oil	0.06	0.06	0.60
License charges	0.20	0.20	0.20
Cost per bbl.	$3.92	$5.36	$6.95

SURVEY OF ENGINEERING PROGRESS

A Review of Attainment in Mechanical Engineering and Related Fields

Thermo-Calorimetric Heating Values of Fuels

By J. Hudler

THE author brings out that a purely calorimetric determination of the heating value of a fuel is insufficient when dealing with fuels containing considerable quantities of moisture. If it should be desired to raise in a boiler the same amount of steam per hour with fuels containing high quantities of moisture as was previously done with coal, it is possible to attain such a result, but only by permitting a higher temperature in the smokestack. The lower production in units of steam per hour due to the burning on one part of the grate of wet fuels must be compensated for by an increased consumption of fuel on some other part of the grate. This can be done by burning more fuel per hour, in which case the initial temperature, owing to the greater amount of smokestack gases, falls off much slower, and the gases go to the smokestack with a higher temperature. Therefore the more moisture the fuel contains the lower will be the useful temperature head as the result of lower initial temperature and higher exhaust temperature, while the amount of exhaust gases per unit of heat will be greater. It is easy to understand what happens when burning fuels with a high percentage of moisture. It is this state of affairs that forced the adoption of larger grates on the new locomotive boilers in Austria.

At the same time, high moisture content of the fuel leads to placing the fuel in a low-grade classification, which, however, is not indicated calorimetrically. Because of this, purely calorimetric testing becomes insufficient. On account of the decisive influence of smokestack temperature on steam output per hour and furnace losses, it is impossible to obtain a clear idea as to the value of various fuels without considering the various furnace temperatures, as these are influenced by the composition of the fuels.

The author proceeds to indicate a method for determining the heating value of fuels which he claims is superior to the straight calorimeter method. The new values are of particular interest for the purpose of comparing fuels to be used for steam generation.

To do this he considers various fuels as being burned under the same boiler with the same excess of air and at the same air temperature, and with the same output of steam per hour, and then determines the useful heat per kilogram (2.2 lb.) of the fuel. This gives a series of values which the author calls thermo-calorimetric heating values. These values are not absolute for a given fuel, but show the comparative values of various fuels, which is just what is necessary to know in purchasing fuels.

If H_u is the calorimetrically determined heating value, W_A the heat loss through unconsumed carbon in the ash, W_V the loss through radiation and conduction of the boiler setting walls, and W_R the loss through smokestack gases, then the useful heat is $W = H_u - W_A - W_V - W_R$. H_u is given; W_A can be determined by ash analysis; W_V may be considered as known for a given installation; as regards W_R, we know the composition and volume of the smokestack gases, but not their outlet temperature. Recourse can, however, be had to an important factor which hitherto has not been sufficiently considered in furnace operation, namely, that each fuel has its specific initial temperature, to which for a given constant output of steam there must correspond a certain outlet temperature. This may not be observed in some cases: in particular, in comparisons between two fuels burned under the same boiler. This may be due to the fact that with fuels which give a higher steam output, lower outlet temperatures have been found to prevail for a given output of steam.

In determining his thermo-calorimetric series of values for the various fuels, the author started with a good grade of coal and assumed that in that event the smokestack gases leave the boiler heating furnace with the temperature of 300 deg. cent. (572 fahr.), whereas, the temperature of the boiler water is 183 deg. On this assumption the heat output per hour, which must be the same for all fuels, is so determined that in each case it becomes possible to compute the exhaust temperature of the gases.

Case of Coal Firing

It is assumed that the coal fired under a boiler has the following composition: Carbon, 0.760; hydrogen, 0.046; oxygen, 0.060; water, 0.040; ash, 0.095; H_u is 7456 large calories per kg.

The author has previously established the following formula:

$$W = C \frac{T_o - T_1}{\log \dfrac{T_o - t}{T_1 - t}}$$

where W is the heat in large calories per hour transmitted to the boiler; T_o the calculated initial temperature in degrees centigrade; T_1 the outlet gas temperature; t the temperature of the boiler water; and C a constant expressing the heated area and the coefficient of heat transmission. Since the actual initial temperature of combustion is smaller than the calculated temperature, an objection might be made to the above formula on the ground that it is apt to give the useful heat head greater than it actually is; but at the moment of its appearance the flame radiates amounts of heat on to the surrounding heated surfaces which are proportional to the difference between the temperatures of the respective surfaces and the temperature of the flame. This heat radiation produces a lowering in the temperature of the flame, whereas in calculation this temperature is determined on the assumption that no heat is being lost from it. Because of this, the temperature head computed on the basis of the temperature T_o determined by measurement would be too small as a basis for establishing the quantity of heat given up to the surrounding surfaces. On the other hand, since the computed temperature T_o is greater than the actual temperature by the amount of heat radiated at the instant of flame formation, the temperature head as determined by computation from this temperature is closer to what actually happens than that determined with T_o as found by measurement to start with.

Before the initial temperature is computed, it is necessary to determine the loss due to the residues of combustion. Thus, if the ashes contain 20 per cent of carbon, equivalent to $0.095/5 = 0.019$ kg., the loss of heat due to this source is equal to $0.019 \times 8100 = 154$ large calories per kg.

In the case of combustion with 50 per cent excess air, the following gases are sent up the smokestack:

$$\left.\begin{array}{l}\dfrac{0.760 - 0.019}{0.536} = 1.382 \text{ cu. m. } CO_2 \text{ with } 1.382\ O_2 \\[2ex] \dfrac{0.015}{0.09} = 0.500 \text{ cu. m. } H_2O \text{ with } 0.250\ O_2\end{array}\right\} = 1.632 \text{ cu. m. } O_2$$

$$\frac{0.010}{0.8} = 0.050 \text{ cu. m. } H_2O$$

$$\frac{0.060}{1.43} = 0.042 \text{ cu. m. } O_2.$$

The minimum oxygen required for combustion $1.632 - 0.042 = 1.590$ cu. m.; add to this 50 per cent excess $= 0.795$ cu. m., a total of 2.385 cu. m., which carries with it 8.768 cu. m. of nitrogen. The smokestack gases have therefore the following composition: $1.382\ CO_2 + 0.550\ H_2O + 0.795\ O_2 + 8.968\ N_2 = 11.695$ cu. m.

The heat content of these gases is 7456 − 154 = 7302 large calories per cu. m., and the initial temperature is therefore $T_0 = 7302$ 11 695 c, where c is the specific heat of the smokestack gases. As this latter varies with the temperature it cannot be determined in advance analytically. But for the present case, the curves of Kusell and Wigton (*Feuerungstechnik*, May 15, 1916, p. 191) give c = 0.3714, which gives for T_o the value 1680 deg. cent. The heat transmission per hour is therefore—

$$W = C\frac{1680-300}{\log(1680-183)-\log(300-183)} = 1245\ C.$$

Every fuel of which the thermo-calorimetric heating value has to be determined must satisfy this output per hour.

As regards the specific heats for the gases at 300 deg. cent. temperature, the following holds good. For carbon dioxide, 0.442; for water vapor, 0.376; for oxygen and nitrogen together, 0.318; whence—

$W_R = 300\ (0.442 \times 1.382 + 0.376 \times 0.55 + 0.318 \times 9.783) =$ 1179 large calories per kilogram.

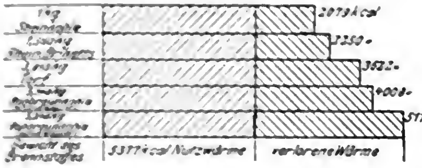

Fig. 1 Heat Balances for Various Fuels

(*First Column, reading down:* 1 kg. coal; 1.560 kg. Rhine briquets; 3.813 kg. peat; 3.340 kg. lignite (47.6 per cent water); 5.246 kg. lignite (60 per cent water); Weight of Fuel. *Second Column:* 5377 large calories, useful heat. *Third Column:* Heat loss. *kcal* = large calories.)

Therefore, if we assume that in the boiler-setting walls the heat loss amounts to 10 per cent or 746 large calories, the total useful heat is 7456 − 154 − 746 − 1179 = 5377 large calories per kilogram, corresponding to an efficiency of 72.1 per cent.

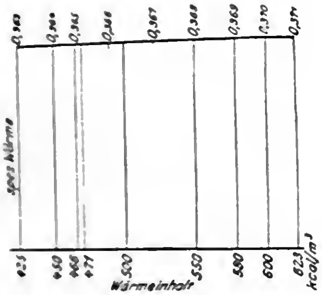

Fig. 2 Relation between Heat Content and Specific Heat of Smokestack Gases (*Spezwaerme* = specific heat; *waermeinhalt* = heat content; *kcal m³* = large calories per cu. m.)

The author carries through the same computation for lignite briquets, two kinds of crude lignite—one with 47.8 and the other with 60 per cent water—and peat. The results are presented in the form of tables and figures. As regards the latter, Fig. 1 is of particular interest as showing the dependence of heat losses on the composition of the fuel and in particular moisture content. From this figure it would appear that whereas the useful heat output remains all the time at the same level of 73.77 large calories, the heat losses rise from 2079 large calories per kilogram in the case of good coal to 5178 large calories per kilogram for crude lignite containing 60 per cent of water. These figures are particularly impressive if we take into consideration their general significance; thus, in order to produce with crude lignite containing 60 per cent water the same amount of useful heat that is produced with 1 kg. of coal, it is necessary to burn on the grate 5¹/₄ times the weight of the fuel, which means not only increased losses in the fuel itself but also a material increase in the cost of handling the fuel. Furthermore, the high-moisture fuels give a low economy from the point of view of ultimate steam generation, because they produce a lower degree of steam superheat.

The following table gives a comparison between thermo-calorimetric values for the various fuels and calorimetric values, which would indicate the comparatively low reliability of the calorimetric values.

	Thermo calorimetric heating value	Calorimetric heating value
Good coal	1 000	1.000
Rhine lignite briquets	0 641	0.656
Crude lignite with 17.8 per cent water	0 299	0.377
Peat with 15.5 per cent water	0 262	0.317
Crude lignite with 60 per cent water	0 191	0.270

The higher the moisture content in the fuel the less the information given by the calorimetric heat value; for example, in the case of crude lignite with 60 per cent water, the error as compared with the thermo-calorimetric value is 41 per cent on the wrong side.

For the purpose of simplifying the calculations involved in deriving the thermo-calorimetric heating value of a fuel, the author worked out the two diagrams shown in Figs. 2 and 3. He finds that if in accordance with the above method of calculations, one should plot a diagram in which the heat values per cubic meter of smokestack gases at the initial temperature of each case are plotted as abscissas and the specific heats thereof as ordinates, it will be found, as appears from Fig. 2, that the line connecting these values would be a straight line. Therefore, if one knows the heat content per cubic meter of a gas, one can read off from Fig. 2 the specific heat directly and thus compute T_o.

The curve in Fig. 3 shows the relation between the initial and the outlet temperatures in accordance with the method of calculation indicated above, and thus makes it possible to read directly the outlet gas temperature for each initial temperature. (*Zeitschrift des Vereines deutscher Ingenieure*, vol. 66, no. 20, May 20, 1922, pp. 495–497, 3 figs., *tA*)

Short Abstracts of the Month

AERONAUTICS (See also Internal-Combustion Engineering)

Flow Tests on Slotted Aerofoils. Data of experiments carried out by Lachmann at Goettingen, Germany, of particular interest because, in this case, the behavior of the eddies at various points and at various angles and velocities was shown by means of sal ammoniac smoke, a method which might be applicable in testing fans, blowers and similar apparatus. Two main flasks are used, one containing hydrochloric acid and the other ammonia.

A third flask serves as a reservoir and from it there is a connection with a tube with one or more jets through which the sal ammoniac vapor passes. The two main flasks stand in a bed of water warmed by a Bunsen burner to assist vaporization. The necessary pressure is supplied by a small pump driven by an electric motor. (*Flight*, vol. 14, no. 22/701, June 1, 1922, pp. 315–316, 15 figs., *d*)

AIR MACHINERY

Rotary Air Compressor with Laminated Springless Blades

NEW ROTARY AIR COMPRESSOR, Dr. E. Loewenstein. The new compressor is of the rotary type with springless abutment blades. The housing A, Fig. 1 is a hollow cast-iron cylinder with end plates eccentrically held in a bearing. The shaft B rotating within carries a cylindrical iron body C with three radial slots D staggered at 120 deg. In these slots are located movable brass plates interleaved with "Vulkan" fiber laminations E, the width of which is equal to the length of the cylinder. On one side the shaft comes out of the cylinder and is held there by a nut. If, now, the shaft B and with it the inner cylinder C are set into rotation, the brass plates E with their fiber laminations are forced by centrifugal force against the walls of the hollow cylinder, providing thereby an airtight joint. Because of the eccentric position of the shaft B, the dimensions of the various air chambers created thereby are non-uniform. On the other hand, the air inlet port F and air outlet port G are so located that the air always enters at the point where the blades project farthest out of the drum, i.e., where the enclosed volume is at a maximum. The air thus enclosed is compressed during the further part of the rotation owing to the gradually diminishing size of the chamber and is forced out under an increased pressure through the outlet orifice G. It follows from this that the volume of air handled and its pressure depend, according to a straight-line law, on the number of revolutions per unit of time. Should it prove that the joint between the blades and the cylinder walls is absolutely airtight, any pressure or volume can be obtained from this type of pump. In actual construction, however, the power consumption is not proportional to the pressure developed. This is explained by the losses due to the friction of the abutment blades against the cylinder walls.

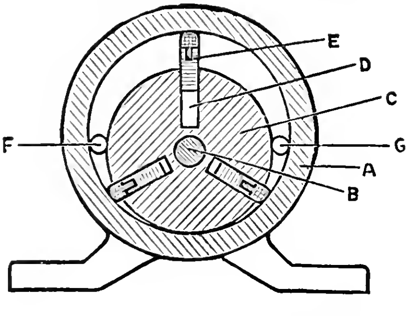

FIG. 1 NEW VALVELESS AIR COMPRESSOR

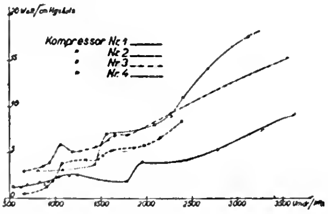

FIG. 2 DATA OF TESTS ON AIR COMPRESSOR SHOWN IN FIG. 1

The results of tests undertaken at the Goettingen Institute for Applied Electricity are shown in Fig. 2, where the abscissas are r.p.m. and ordinates, watts of power consumption per unit of pressure rise expressed in centimeters of mercury. The compressors Nos. 2, 3 and 4 in which the efficiency appeared to be rather low had blades made of brass without fiber laminations. Compressor No. 1 had brass laminations alternating with laminations of Vulkan fiber. Other tests showed the relation between air-gage pressure and speed in revolutions per minute.

The compressor may be built in very small units to be driven by a motor ranging from $^1/_{16}$ to $^1/_6$ hp. (*Deutsche Optische Wochenschrift*, vol. 8, no. 22, May 28, 1922, pp. 413–414, 4 figs., *de*)

ENGINEERING MATERIALS (See also Special Processes)

Fatigue of Metals

FATIGUE OF METALS, C. E. Stromeyer. In a paper read by the author before the Royal Society an empirical law of fatigue was proposed, expressed in the following formula:

$$S = Fl + C\ (10^6/n)^{1/4}$$

where S is the alternating stress which will cause failure after being repeated n times; Fl is the fatigue limit of the material and C is a constant. The original fatigue-testing machine used by the author was unsatisfactory. Recently, however, the Committee of the Manchester Steam Users' Association for the Prevention of Boiler Explosions ordered a larger machine, which permitted the thermometric and elastic determination of the fatigue limits. It was found that these and the calorimetric and extrapolation determinations were in close agreement, so that there are now available three quick and one slow method of determining this very important point. This machine is described in the original article.

It has been found that as soon as the fatigue limit is reached, what may be called molecular friction takes place in the sample which generates heat, and this can be detected either calorimetrically or by means of very sensitive thermocouples and galvanometers; at the same time the elastic properties of the material undergo a change, which can be determined by suitable instruments.

The first question to be settled is whether the fatigue limit is affected by permanent stress, and with this end in view Woehler's tests on wrought iron have been analyzed, as follows: His test results were entered on a diagram and with the modified fatigue law the fatigue limits were estimated by extrapolation. They evidently decreased with increasing permanent stress. The best argument with the experiments is obtained by assuming an ultimate strength estimated not on the original section of the sample but on a reduced section, this stress being therefore higher than the usual accepted ultimate strength. It sounds paradoxical that even for a single fatigue stress the fatigue limit should be higher than the ordinary ultimate strength, but this can happen.

Thus, Woehler tested the wrought-iron sample, which had a tenacity of 21 to 21$^1/_2$ tons per sq. in., yet when he subjected it to alternating stresses ranging from zero to 23 tons it resisted them 800 times.

The following are the results of the author's own tests on mild steel, the only ones which have ever been made for the determination of the fatigue limits of permanently stressed samples. With an average compression stress of 0.46 ton, the fatigue limit was reached with an alternating stress of ±11.4 tons, the range of stress being from 15.86 tons compression to 6.94 tons tension. With no permanent stress the limit was reached with 10.87 alternating stress and with an average tension stress of 4.47 tons the fatigue limit was reached with 9.32 alternating stress, the range being from 4.85 tons compression to 13.79 tons tension. The results when plotted do not lie on a straight line, but suggest a parabolic fatigue curve. The test results obtained are compared with the formula in a table, which shows that the two agree reasonably well. It is evident that as the expression following C in the above formula is large for the case of a single application of stress causing rupture, it would have to be multiplied by a factor $(T - Fl)$, where T is the ultimate stress and Fl is the fatigue limit where the permanent stress is P. When $P = 0$, $Fl = Fl_0$. Apparently, T would have to be chosen higher than the ordinary or static tenacity, in order to harmonize the result, and possibly the stress on the contracted, instead of the original, area would have to be taken. It was also assumed that the fatigue limit varied from Fl_0 to $Fl = P$ when $P = T$, and the curve marked fatigue limit was assumed to be a parabola.

The author gives a highly interesting diagram combining many of his results. Woehler, being unable to determine the fatigue limits, could only give the results which are shown in the original in a table and the empirical formula, and had to find this curve by extrapolation. That the fatigue-limit curves are not far from the truth is evident from the fact that the fatigue stresses in the table, which have been estimated with the help of the formula, are in close agreement with the actual stresses. It will also be seen that the ringed crosses in the diagram fall very close to the respective curves or cycle contours.

The arrowheads indicate the positions where this formula would have placed the results. The complete formula is:

$$S = [P + Fl_0 (1 - P^2/T^2) + KTM]/(1 + KM)$$

Here S is the combined permanent stress P, plus the fatigue stress which will cause fracture after n repetitions. Fl_0 is the fatigue limit of the material when there is no permanent stress P. In this case Fl_0 is 7 tons. The enhanced ultimate strength is T, and in this case it appears to be 26 tons. K is a coefficient which in this case is 0.30. M stands for the expression $10^6/n^{1/4}$. Thus, for this sample of iron:

$$S = [P + 7(1 - P^2/676) + 13.8M]/(1 + 0.3M)$$

For no permanent stress we have the region marked "Piston Rods;" it embraces all similar cases like connecting rods, watch springs, etc. The practical working limits of stress seem to be 3 tons for wrought iron, so that here the factor of safety is about $2^1/_3$.

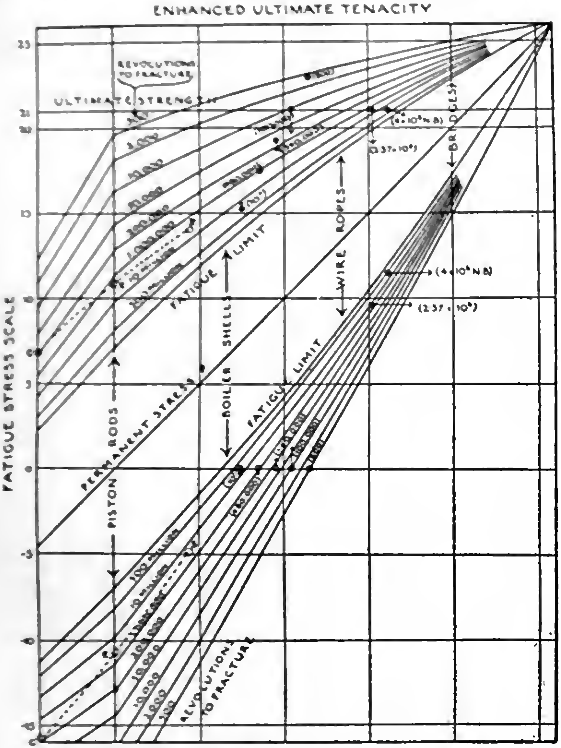

Fig. 3 Fatigue-Limit Curves

For short objects, where no buckling is possible, higher stresses are allowed. The inner tubes of large guns should occupy a position in the diagram very close to "Piston Rods," for when at rest they are subjected to severe compression stresses, whereas under pressure they are subjected to tension or rather shearing stress. As far as can be ascertained, both these stresses fall outside the fatigue-limit curve, which would mean that the factor of safety of inner gun tubes is less than one. This need cause no alarm; it means that the inner gun barrel will ultimately fail; but, according to the diagram, it will stand a definite number of repetitions of stress. In fact, partly for this reason, partly on account of wear and tear, the inner gun barrels are renewed after a certain number of rounds, say, 2000.

To the left of the "Piston Rods" region is one marked "Boiler Shells." The average stress—in this case it can hardly be called the permanent stress—is half the working stress. When at rest there is no stress; when under pressure the permanent and alternating stresses are added together. According to Fig. 2, the fatigue limit is reached when the combined permanent and alternating stress is about 13 tons. In practice a stress of about $5^1/_4$ tons for wrought iron of 21 tons is considered safe, and explosion stresses do not fall below 8 tons even with heavily corroded shell plates. Here, then, we have a factor of safety of about 2.5, using the fatigue limit as a basis. This comparatively large factor seems to be due to sentiment or fear. It is a justifiable one, for piston rods and connecting rods do occasionally break, their factor of safety being somewhat low, whereas boiler shells never burst at less than 8 tons stress if of iron. No cases are known of acid open-hearth shell failures, but basic-steel failures are frequent on the Continent and in America.

To the left of the "Piston Rods" region, but outside the diagram, would be placed "Boiler Furnaces," because their stresses range from 0 to a maximum compression stress. For long furnaces the factor of safety based on the fatigue limit is about 12. This is due to considerations about buckling and overheating, and the impossibility of insuring perfect circularity of shape. In a recent test, ovality of $^3/_4$ in. in a 36-in. furnace led to collapse when the mean stress was 2.0 tons. The bending stresses were, of course, very severe, the ovality having increased to nearly 3 in. just before collapse took place.

The next region in the diagram is marked "Wire Ropes," but embraces many objects in which the fatigue stresses are not quite as severe as the permanent stresses. This region also embraces the tension members of short bridges, in which the live stresses are relatively very severe.

"Bridges" occupy the extreme right hand of the diagram. Here the permanent stress is very severe and the alternating stress very light. This region differs essentially from that of "Piston Rods" and inner tubes of guns because the range from the fatigue limit to the breaking stress is very narrow, and whereas with guns of wrought iron the fatigue limit may be exceeded by 6 tons with a reasonable certainty that such stresses may be repeated one million times without failure, the diagram shows that the same limited life would be reached in heavy bridges if the fatigue stresses were increased over the fatigue limit by only a fraction of a ton. (Paper read May 25, 1922, before the South Wales Institute of Engineers, abstracted through the *Iron and Coal Trades Review*, vol. 104, no. 2831, June 2, 1922, pp. 822–824, 2 figs., *etA*)

White-Metal and Brass Bearing Materials. A general discussion of the subject, with particular reference to German practice. One of the tables gives compositions for white-metal alloys as used by the Prussian and Bavarian State Railways and in commercial practice in England. Data are also presented on aluminum bronzes with 10 per cent aluminum content and also titanium-aluminum bronzes, and a table is given showing the variation in physical properties of these bronzes with their heat treatment. Another table gives the melting points and freezing points of the various lead tank alloys, beginning with 120 lead to 140 parts tin and ending with 240 lead and 150 parts tin. As a good metal for wheel bearings the following composition is recommended: 72.4 parts copper; 4.7 parts tin; 29.9 parts zinc; 0.5 part iron and 1.5 parts lead. (*Zeitschrift fur die gesamte Giessereipraxis*, vol. 43, no. 23, June 10, 1922, pp. 316–317, *g*)

Causes of Failure in Cast-Iron Pipe, F. A. McInnes. Among the causes of failure not sufficiently safeguarded in specifications is the quality of the iron in the pipe. The specifications require the test bars to support a center load of 1900 to 2000 lb. and to show a deflection of 0.3 in. before breaking. The weak point in these requirements lies in the fact that no direct connection is made between the loading and deflection, with the result that in many cases the test bars do not show 0.3 in. deflection until the load is in excess of 1900 or 2000 lb., oftentimes largely in excess. The author shows that of 2183 test bars broken by the Metropolitan Water Board of Massachusetts during the past 9 years less than a half showed the proper deflection at the specified load, which would indicate the use of metal of widely different quality, varying from very hard to very soft. The author objects to establishing a specified composition of the iron, but believes that permissible sulphur content at least should be specified. With this provision, together with a logical relation between flexure and breaking load fixed in the test-bar requirements, a long step forward toward uniform and satisfactory iron will have been taken. (*Engineering and Contracting*, vol. 57, no. 24, June 14. 1922, pp. 563–564, *p*)

Improved Nickel Silver. The appearance of stainless steel has called increased attention to the necessity of research in the field of non-ferrous alloys for the purpose of finding those having the same property of "stainlessness."

One such alloy recently developed is an improved form of nickel silver containing a much larger percentage of nickel than does the ordinary alloy. This metal is harder and of a color more nearly approaching that of silver than ordinary nickel silver and costs about one-third less than stainless steel or iron.

Furthermore, the same research has resulted in the production of a more homogeneous metal than formerly, and as this means greater ductility it will now be possible to make deep stampings and pressings from sheets of alloys with a high nickel content. It is stated that spoons and forks made of such alloy can be produced at less than half the cost of such goods made of stainless steel or iron. (*Brass World and Platers' Guide*, vol. 18, no. 6, June, 1922, p. 195, *g*)

FOUNDRY

Cast Nickel-Chromium Alloys, E. F. Lake. Description of melting and casting of three grades of nickel-chromium alloys as practiced by the Hoskins Manufacturing Co. of Detroit. One grade contains 80 per cent nickel and 20 per cent chromium, with only traces of iron; a second grade is composed of 85 per cent nickel and 15 per cent chromium; while a third grade carries 64 per cent nickel, 11 per cent chromium, and 25 per cent iron. Only electric furnaces are used for this purpose, the equipment consisting of one 2-ton arc electric furnace of the Heroult type, two induction electric furnaces and three crucible-type resistance furnaces. The metals used for making these alloys are chromium (free from all impurities except iron), electrolytic nickel, and a small amount of shot nickel; and for the third alloy, 99.7 per cent iron.

Carbon must be kept out of these alloys as it increases their tendency to oxidize at high temperatures; occluded gases are also very bad. One of the reasons for using shot nickel is because it reduces the hydrogen content in electrolytic nickel. Good chrome-nickel alloy can be made without shot nickel when nickel free from hydrogen (Mond) is used.

A melt in the induction furnace generally consists of from 550 to 650 lb. From 325 to 375 lb. of this is usually drawn off into the ladle for each cast. This leaves a heel of from 225 to 275 lb. to start a new melt. In that way each melt can be drawn off in less than two hours, or five melts in nine hours.

The molds have to be very dry. One way of accomplishing this is by a coil of resistance wire dropped into the mold and heated by an electric current. It would appear that the alloy flows freely and does not chill quickly enough to cause cold shuts. Tubes have been cast with 1-in. cores and $^1/_4$ in. of metal around them in lengths as great as 40 in. Considerable trouble was encountered at first, the greatest difficulty being to anchor the long core so that it would not sag or float. These tubes are cast in pairs with no risers. (*The Foundry*, vol. 50, no. 11, June 1, 1922, pp. 452–454, 6 figs., *d*)

FUELS AND FIRING

Froth-Flotation Tests on Bituminous Coking Coal, Oliver C. Ralston and Gaichi Yamada. Data of research on applicability of froth flotation to the treatment of the fine size of coals of the Pacific Northwest, carried on by the Northwest Experiment Station of the Bureau of Mines in coöperation with the University of Washington, at Seattle. Only the conclusions of this interesting article can be reported here.

Tests on a bony coking coal from the Wilkeson mine, at Wilkeson, Wash., have shown that the cleanest coal can be floated first, the bony coal next, and the ash last by ordinary froth flotation. Very thin oils or soluble frothing agents work best. The fine sizes of coal float the most easily and the coal in the very fine slime will float to some extent without the use of any flotation oil whatever.

Due to the tendency of fine sizes to float so easily, they are probably "overboiled" and produce dirty concentrate when enough oil is added to float the coarser sizes. Screen analyses of the flotation concentrate show increasing percentages of ash in the finer sizes.

To take due advantage of the above facts, it is necessary to use a flow sheet in which roughing treatment is followed by cleaning of both concentrate and tailing from the roughing cell, discarding as tailing material which will not float in any of the retreating cells. Retreatment of middling with original feed is not desirable except for the middling obtained in cleaning the rough concentrate.

By this method of treatment a clean concentrate can be obtained; the bony portion of the coal forms a middling which may have a market value, and the tailing is too low in coal to be of any value.

Attempts to control the flotation tests by sink-and-float tests with heavy solutions have failed on the fine sizes of coal, due to their supposed porosity. (*Chemical and Metallurgical Engineer*, vol. 26, no. 23, June 7, 1922, pp. 1081–1086, 2 figs., *eA*)

GAS PRODUCERS

Ash Fusion Gas Producers

Ash-Fusion Gas Producer, M. A. Fichet. Description of a type of gas producer in which the temperature is such as to obtain a fused slag. The idea basically is not new and was described by Ebelmen in a paper before the French Academy of Sciences in 1842.

The author also states that he saw in a small forge in Savoy an apparatus of this character which had been in operation for over twenty years. In developing apparatus based on this same principle the author made certain improvements, one of the first being the elimination of the use of steam and hot air and the substitution of cold air. It was found that complete fusion of the ash can be thus obtained, but not with every coal, as it was found that in various coals the fusion point of the ash varied from 1178 to 1500 deg. cent. In addition, it was found desirable to lower the melting point of the ash by the addition of fluxes, so as to produce a slag containing the silicates of several bases, alumina, lime, magnesia and the oxides of iron and other metals. The composition of this slag was found to resemble that of common glass.

Ashes of this composition when heated to proper high temperatures first soften, and then are converted into a pasty condition and finally melt. In softening, the material becomes sticky and has the tendency to agglomerate and form an impermeable mass with the fuel, preventing the passage of the gas through it. Furthermore this pasty mass tends to stick to the walls of the producer. In the pasty state of fusion the half-melted materials can surround the particles of fuel and subject them to the oxidizing action of the air. There are two dangers that must be avoided at this point. If the material sticks to the hot walls of the crucible, then the coal can no longer be fed into the crucible in a regular manner; if the cooled mass becomes covered over with a skin, then the regular course of the combustion is interrupted, the temperature decreases, the mass solidifies and it becomes necessary to break up the congealed mass with a pick, which is a very troublesome procedure.

It is for the purpose of avoiding this double danger that steam is introduced at the base of the boshes. When the water vapor comes into contact with the incandescent carbon it is decomposed, with the production of water gas. As this reaction absorbs a considerable quantity of heat, a sudden decrease in the temperature takes place, which allows the fulfillment of the condition that the high temperature of the crucible should not reach into the boshes.

There are therefore three successive stages in the gasification of the coal in this apparatus:

1 In the crucible—the production of producer gas, with fusion of the ash
2 In the boshes—drop of the temperature, with the production of water gas
3 In the shaft—distillation of the coal, with the production of illuminating gas.

In the case where coke is used as the fuel, the last step does not exist. The proportion of illuminating gas in the final mixture depends on the nature of the coal, i.e., whether it is high in volatile matter or not.

The gas produced from coke containing 15 per cent of ash had the following composition: carbon monoxide, 41.62 per cent; hydrogen, 1.08 per cent; carbon dioxide, 1.75 per cent; nitrogen,

55.55 per cent. Every kilogram of the coke gave 4644 kg. [this figure is obviously an error; perhaps, 4.644 cu. m. is meant] of gas, which had an average calorific power of 6100 cal. Such a product was obtained with the use of an air blast at a temperature of 300 deg. cent. and the injection of steam at a point above the lower end of the boshes.

In order to obtain the effective heat value of the gas leaving the gas producer, it is necessary to add the 998 cal., in the gas at the temperature of 760 deg. cent. to the above value of 6100 cal. On the other hand it is necessary to subtract 230 cal. carried out in the hot air leaving the gas producer at a temperature of 300 deg. cent., and the 293 cal. carried out in the steam. This leaves a final net value of 6554 cal. as the true heating value of the gas.

The thermal efficiency of the process is therefore 6554 cal. divided by 6868 cal., or 95.5 per cent. The 6868 cal. represent the heating value of 850 grams of carbon in 1000 grams of coal after the deduction of 150 grams of ash.

It is claimed that in gas producers operating with fusion of ash it is possible to build units capable of gasifying 2500 kg. (5500 lb.) of fuel per hr., and in addition it is possible to utilize coals of very poor quality. Thus, coke containing as much as 40 per cent ash can still be used in this apparatus and give gas of good quality.

There are now several types of gas producers which gasify coal with fusion of the ash. Among these the Rehmann producer is of particular interest because of its novel construction. This is a German invention and is shown in Fig. 4. The crucible is shown at *a*, the boshes at *b* and the shaft at *c*. A hole *h* is also provided for introducing a tool for raking the coal. The apparatus is a large one. The diameter of the crucible is 2 m., that at the center of the shaft 3.6 m. The producer is furnished with air and steam tuyeres. The shaft is surrounded with an annular chamber which is used to catch the dust that may be present in the gas. The cross-sectional area of this chamber is quite large, so that the gas passes through less rapidly. A valve is provided at the side of the chamber to release the pressure in case of an explosion.

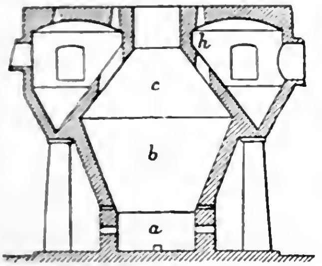

Fig. 4 Rehmann Ash-Fusion Gas Producer

While it is not certain that this apparatus has been used practically, it represents a distinct advance in design and indicates the interest that is being shown in this type of gas producer. The many advantages that it offers, the simplicity of construction, the ease of operation, the good quality of gas produced, the efficiency of the gasification, the low initial cost, all are said to tend to point to the ash-fusion producer as the logical gas producer of the future. (*American Gas Journal*, vol. 116, no. 24, June 17, 1922, pp. 550–552, 2 figs., *d*)

HYDRAULIC ENGINEERING

The Hydrautomat

The Hydrautomat. Description of a new and simple device by which a low fall may be transformed under certain restrictions into a high fall, or water can be lifted to a considerable height without the use of rotary or reciprocating pumps. The device essentially consists of a series of tanks connected by piping in proper ways.

The principle of the device is illustrated in Fig. 5. If we deliver water under a head into the bottom of a closed chamber *A*, the air in that chamber will escape upward if it possibly can. An air-vent pipe is therefore provided connected also to the top of another closed chamber *B* which is supposed to be full of water. Then if the air enters at the top of *B* it will exert pressure on the upper surface of the water. If there is a pipe from the bottom of the upper tank *B* to a still higher tank *C*, the water will be delivered into tank *C* provided the vertical distance is within limits. Now, assume that the process is reversed and that if water is discharged into *A*, the lowest tank of the three, it shall fall through a discharge pipe to the ground. A partial vacuum is thus caused at the top of the tank *A*, hence, also in the second or intermediate tank *B*. Evidently, if we throw open a valve which allows tank *B* to suck up water from below, it will replenish itself with liquid to replace the outgoing air. Here atmospheric pressure is used and a column of air acts to some extent as the piston of a pump. This combination of atmospheric pressure with the pressure of water is what constitutes the novel principle of the hydrautomat. The inventor, T. G. Allen, uses compressed air for his forcing stroke, obtaining the compression by falling water and a partial vacuum for his suction stroke, this vacuum also due to falling water.

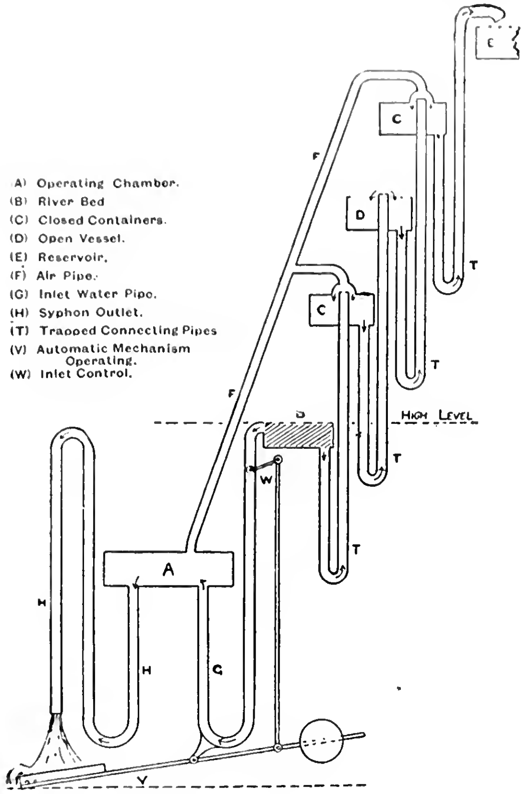

Fig. 5 Diagram Showing the General Principle of the Allen Hydrautomat

The cycle of the hydrautomat is as follows:

Pressure Stroke. This is caused by the weight of the water column, which flows into the closed chamber *A* at low level from the head race; this incoming water compresses the air in this closed chamber, and forces it out along the air-conducting pipe, whence it enters an overhead closed tank (or tanks). The effect is that the water in the overhead tank *C* is, in its turn, forced out and pushed up into a still higher tank *D*. This is an open one. One complete flight of the ascent is thus accomplished. At the end of this pressure stroke the closed operating chamber *A* at low level and the open tank *D* are full of water, but the overhead closed tank *C* is full of air.

Suction Stroke. This is governed entirely by atmospheric pressure. The contents of the closed chamber *A* at low level are drawn down, and discharged into the tail race. Simultaneously the inlet from the head race is automatically closed. The closed operating chamber then begins to feel a vacuum, and this vacuum extends

to all the other higher closed tanks through the medium of the air-conducting pipe. In consequence, the water in each open tank (these being now full) is sucked up one flight into the next higher closed tank. At the end of this suction stroke the operating chamber and open tanks are empty and the closed tanks are full of water. The inlet from the head race is then automatically opened, pressure water is admitted, and the pressure stroke is recommenced.

The pipes between the tanks are all water sealed, so that all non-return valves or mechanical checks are dispensed with. The apparatus has no moving parts other than an opening and shutting sluice gate. It is entirely self-contained, and provides its own motive power. The operation is continuous. The contrivance requires no housing, attention, or supervision. There is nothing which can wear out or lose adjustment. It may be constructed from timber, steel or concrete; in fact, from any material which can be made watertight, or practically so.

The inventor claims for his device an efficiency of 80 per cent. It should be clearly understood, of course, that only part of the falling water is lifted to a greater height and the proportion of water lifted is dependent on the height, so that, for example, if we have one gallon a second falling 3 ft. over a sill, this can be converted into 8 gal. per sec. falling through 30 ft. It is expected that this device might be extensively used for purposes of irrigation. (*The Electrical Times*, vol. 61, no. 1600, June 15, 1922, pp. 573–574, 2 figs., *dA*)

INTERNAL-COMBUSTION ENGINEERING (See also Railroad Engineering)

Siemens-Halske 60-Hp. Five-Cylinder Radial Air-Cooled Engine. Under the Versailles Treaty Germany is limited to the use of engines not exceeding 60 hp. for single-seater civilian aeroplanes for the next two years. Because of this limitation of power, one may look forward to see considerable progress made in the efficiency of German aircraft. Since the Germans, if they wish to fly at all, will have to make such improvements in aircraft as will enable them to do the work with the limited power permitted.

The new Siemens-Halske engine comes within the permissible limits of power. No figures as to weight, revolutions, fuel consumption, etc., are available. It is known that the engine has five cylinders and is of the four-stroke type with two valves to each cylinder. The bore is 100 mm. and the stroke 120 mm. The cylinders are of steel with aluminum jackets having fins machined on them for cooling and the pistons are of aluminum or aluminum alloy.

The inlet valve is operated by double rockers actuated by a push rod from the cam gear on the front of the engine. The exhaust valve is operated also through push rods by a single rocker arm placed between the two rockers of the inlet valve. All rocker arms are carried in ball bearings.

The valve-stem guide of the exhaust valve is situated inside a tubular T-piece, so that the exhaust gases escape through two openings. It is believed that the manufacturers have designed a standard exhaust-ring collector for this engine, so that from each exhaust-valve cage, two short L-pipes run to the exhaust ring, which is placed behind the cylinders and from which a single exhaust pipe projects upward. In the standard form the engine is provided with one magneto and one spark plug per cylinder, but dual ignition may be installed. (*Flight*, vol. 14, no. 23/702, June 8, 1922, pp. 326–327, 3 figs., *d*)

MACHINE PARTS

Autopitch Gear

Autopitch Gear. Description of a new gear proceeded by a brief historical discussion on gearing in general.

In starting on his work the inventor of the autopitch gear, W. Rus Darling, compiled the following list indicating the requirements of a perfect gear: (1) Strength sufficient to insure safety; (2) durability unlimited; (3) adaptability to all possible variation of conditions; (4) elasticity sufficient to absorb unavoidable vibrations of other parts; (5) noiselessness approaching to silence; (6) economy both in cost of production and in power. Of this list the third requirement appears to be the most difficult to fulfill, the others being within the scope of modern knowledge and practice.

In considering various types of gears, the author came to the conclusion that the old mill wheel with its continuous stream of water "gearing" into it, adapts itself to almost any conceivable variation of a nature corresponding with those to be met with in mechanical gears. If the mill stream could be rolled up into a circle of a suitable diameter and provided with a shaft and bearings, it would form a pinion of the required adaptability. Machine-cut teeth are not always correctly shaped. The bearing between opposing teeth may be only at a point, or points, instead of on a line the full width of the wheel. But even this line contact when acquired is not a mechanical ideal. Teeth slide as well as roll and concentrated pressure and friction are therefore of great importance, and it is only the high quality of the material available that enables thousands of horsepower to be transmitted through one, two or three lines of contact of 1-, 2-, or 3-ft. lengths.

The oil film plays an important part. If this volume of oil is actually constant it must be concluded that the pressure, the wear, and the transmission are all effected through its medium. It is estimated that in modern high-speed gears the period of contact is about one one-thousandth of a second, and from that fact is deduced the retention of the oil film.

From the foregoing it may be reasoned that the thicker the film the better, and to carry this reasoning to its logical end, if the teeth of one wheel were eliminated and only the oil left, the theory of the endless mill stream would be realized in practice. While this cannot be actually done, the question is how near can one get to a continuous oil film.

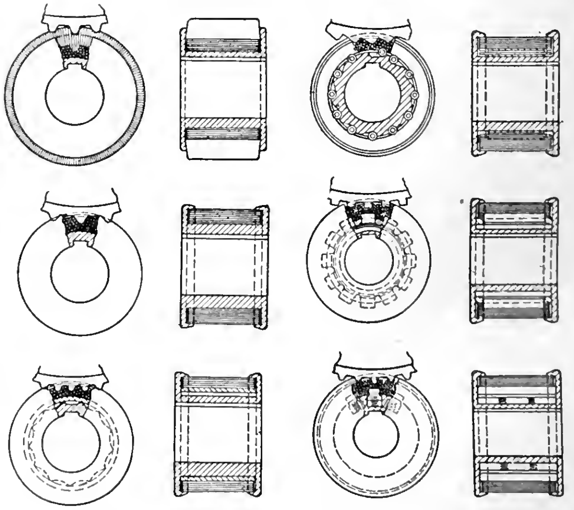

Fig. 6 Autopitch Gear

Reverting to the rational forms and materials of gear teeth, it is found that the finer the pitch, the closer together and therefore more nearly continuous become the successive films of oil. But if the teeth are made too fine to carry the load, all the advantage is lost. It must be concluded, therefore, that for the present, at least, the continuous film is impossible in practice. On the other hand, however, there is an element which is neither a fluid nor a solid and yet possesses something in the nature of both. The only familiar form of it is found in balls. If a number of balls are poured into a vessel, they will find a common level; if run out on a table, they will behave much like water. Rollers behave somewhat similarly but can only flow in two opposite directions, and it is this limitation that enables them to be harnessed in the form of an endless mill stream within the compass of an ordinary pinion as indicated in Fig. 6. This illustration shows how this "semi-fluid" can be controlled and kept in its appointed place. The density of the element may be varied by having more or fewer rollers in a given space; each roller being supported by all the others; their individual diameter does not materially affect their strength as a combination, which, in fact, forms one solid "fluid" tooth, equal in thickness to almost the circumference of the pinion.

Reverting to the "absurd" proposition of a continuous oil film, it may be seen how nearly approach has been made to its realization. It is at once apparent that each roller provides a line of contact with the engaging wheel tooth, so that, instead of one line of contact per tooth, there is a number varying with the depth of gear mesh. Further, each roller has a film of oil over its entire length and circumference, therefore there is actually that continuous oil film which was previously thought absurd. Not only that, the metal-roller element upon which the film is built is almost as fluid as the oil itself.

The pinion of the construction shown is able to accommodate itself to any straight tooth in a wheel and will continue to do so until the tooth is entirely worn away. It is therefore independent of the contour and thickness of the tooth; also the teeth may engage with it at any point of its circumference and the engagement is thus independent of pitch. This eliminates the necessity of having the teeth geometrically designed and also indicates that irregularity of pitch and missing teeth will not interfere with smooth and continuous running. Further, there are no tooth clearances and therefore no backlash. Other irregularities are provided for in the fact that the rollers are free to incline in either direction across the face. The alignment may be faulty, parts may expand or contract, the foundations may warp and twist without materially affecting the gear. (Paper read before the Institution of Engineers and Shipbuilders in Scotland, abstracted through *Engineering Production*, vol. 4, no. 88, June 8, 1922, pp. 545–548, 24 figs., *dA*)

MACHINE SHOP

Grinding-Wheel Breakage and Its Causes, Harold E. Jenks. A general discussion of the causes producing stresses that result in wheel breakage. The author lists eleven primary causes that may produce the breakage of a grinding wheel while in operation. Among these, particular mention may be made of overspeeding and heating of the wheel. As regards overspeeding, the author states that reliable grinding-wheel manufacturers test all wheels before they leave the factory by running them at a speed approximately twice that for which they are designed and recommended, thus obtaining a factor of safety of about four, and because of this breakages due to speed are few in number. They occur occasionally from such causes as shifting thoughtlessly from large to small pulleys, placing wheels of large diameter on spindles running at speeds intended for smaller diameter, or substituting for a wheel running at the correct speed, one of different grain and grade designed for lower wheel speeds. In other words, most of the breakages due to overspeeding are really due either to carelessness or ignorance on the part of the operator.

As regards heating of the wheel, the author states that stresses due to this cause and produced by the unequal expansion of different parts of the wheel may account for many breakages. Stresses produced through excessive heating of the wheel are similar in character to those produced by centrifugal force and are of two kinds, radial and tangential. The greatest tensile stress is apt to occur at the circumference of the hole and hence combines at that point with the maximum tensile stress due to the centrifugal force. This is important as both these stresses may be large and their resultant may easily cause breakage.

A few years ago the writer assisted in making some tests of the effect of heat alone upon grinding wheels. An electric heating coil was arranged to cover the entire surface of the face of the wheel to be tested, and heat was gradually applied. The wheel was not in motion, so that the effect could be due only to heat. At a temperature of the circumference averaging from 70 to 115 deg. cent., the wheels tested cracked along the diametral plane, some with sufficient force to entirely separate the two halves of the wheel. With the heat thus applied, from 40 to 70 min. elapsed before breakage occurred. It should be borne in mind that the stress due to centrifugal force was not present in these tests, so that it is reasonable to conclude that under similar heating conditions a wheel of the same type in operation would break at a still lower temperature and probably in a shorter time. Actual heat breakages in operation are in very close agreement with this condition.

As stated above, the typical heat break is a diametral crack, the same as in the case of breakage due to centrifugal force. It is evident that a fracture resulting from a combination of heat and speed stresses would be of the same type.

Tight or insufficiently lubricated bearings on a grinding machine may cause heating of the spindle wheel. In case the wheel bushing fits the spindle tightly, the expansion of the latter may cause tensile stresses of considerable magnitude in the wheel. This is clearly the case of a thick cylinder under internal pressure. The stresses produced are similar in character to both those due to centrifugal force and those due to heating of the wheel. They are of two kinds, radial and tangential, as in those cases, and the maximum tangential tensile stress occurs at the circumference of the hole. Hence the maximum stresses would combine at that point and breakage might occur from the resultant stress. The typical break due to heating of the wheel spindle would be a diametral crack, as in the case of breakage due to centrifugal force. MACHINE TOOLS (See also Machine Shop)

Electrodepositing Iron on Steel

"Putting on" Tool for Steel Parts, David R. Kellogg. Description of apparatus and process for electrodepositing iron on steel. The process is a development of the method first described by Thomas and used in the British Army repair shops and also in commercial work. The solution used by Thomas consisted of 75 grams of crystallized ferrous ammonium sulphate per liter of water and was used cold at low current density, namely, 0.33 ampere per sq. dm. Under these conditions the deposit was smooth, bright and adherent, and withstood bending and chipping.

The extensive series of tests undertaken at the Westinghouse Research Laboratory made it possible to lay down a fairly definite set of rules of procedure, by following which one could be sure of a good coating. After most of the grease had been removed from the piece to be coated, and the portions on which no deposit was desired had been covered with a mixture of 90 per cent hydroline (M.P. 100 deg. cent.) and 10 per cent paraffin, it was made the cathode for three minutes in a 10 per cent solution of commercial lye and sal soda in equal proportions. From three to five amperes per square inch were used in this portion of the cleaning—the exact figure, as well as the exact concentration of the solution, being, according to the original article, of no moment. The piece was then washed in running water and made the anode for an equal time in 30 per cent commercial sulphuric acid, using about the same current density. In the acid-cleaning bath it is important to have the current density sufficiently high so that the iron becomes passive and gasses freely. If too low a current density is used, the piece is attacked by the acid and cleaning does not take place. With sufficient current to produce passivity, as indicated by free gassing of the work, the piece comes from the acid-cleaning bath with a beautiful pearly luster, and upon washing in running water and transferring to the plating bath without touching in any way the cleaned portion or allowing it to dry, a satisfactory coating is obtained. While the work is in the acid-cleaning bath, any motion of the work will sometimes result in a decrease in current and cessation of gassing of the work, showing that it has become active, i.e., is being attacked by the acid. When this tendency is very pronounced it is an indication that the current density is too low. After cleaning in this manner and transferring immediately to the plating bath, it was found possible to produce satisfactory coatings at the rate of 0.0059 in. per hr., corresponding to a current density of 1 ampere per sq. dm., which is three times the rate attained by Thomas.

This process gave smooth, tough, adherent coats which, when deposited on a carefully ground rod 0.485 in. in diameter and then ground to a thickness of 0.001 in. (0.025 mm.), could be pressed through a hole in 1-in. cold-rolled steel 0.0005 in. smaller than the finished size of the rod, and then pressed back again with no signs of stripping. These test rods could be bent and mishandled in various ways with no damage to the coat.

A motor shaft having bearings 0.625 in. in diameter by 1.5 in. long was purposely finished 0.002 in. small in diameter, plated oversize, reground on proper dimensions, and then assembled

and run in bronze bearings for 1000 hr. with a load of 50 lb. per sq. in. of projected area, using a short stiff belt with a clipper joint in order to give a pounding effect as well as friction. At the end of the run it was found that the wear was 0.0002 in., which is just a trifle less than the original material shows in factory life tests. Plug and thread gages have been repaired by this means and have given good satisfaction, although they are not as hard as heat-treated tool steel.

Next, experiments were made with hot concentrated bath and stirring, the solution used being 300 grams of ferrous ammonium sulphate per liter. The deposits obtained with useful current densities up to 10 amperes per sq. dm. were softer than those from the cold bath, perfectly adherent and of a velvety appearance. This method gave a greater increase in the rate of deposit than corresponded to the increase in current density.

One of the uses suggested for the deposition on cast iron is in giving cast-iron bearing shells a preliminary coating of pure iron so that they may be tinned and the babbitt made to adhere directly to the shell as in the case of bronze shells. This would do away with the necessity for the anchor holes and enable the use of a layer of babbitt about one-third as thick as that used in cast-iron shells with anchor holes.

Attempts to produce a coating while the work was revolving in a horizontal position did not succeed. On the other hand, numerous tests on the working qualities of deposits produced by the successful methods proved the high quality of the material of the coatings and their perfect adherence. While there are several methods of producing good-looking deposits, such deposits for all their good looks may prove to be hard, brittle and lacking in adherence. It seems that only by bending, hammering and cutting can a satisfactory test of working qualities be obtained. (*The Electric Journal*, vol. 19, no. 6, June, 1922, pp. 249–251, *ep*)

Tool for Turning Down Nuts. Description of an electric tool designed for turning down nuts, cap screws, wood screws, and similar fastenings, and arranged to operate in either direction. The machine may be made either stationary or portable. The novel feature is the driving mechanism of the tool, which incorporates a multiple-disk slip clutch, adjustable for any tension within the capacity of the motor and operating through a spline shaft to a positive clutch. The arrangement is such that the positive clutch automatically disengages when the disk clutch fully releases, thus relieving the driving spline from torque. This permits the removing of the wrench, chuck or screwdriver from the driven member and their engagement with the new nut or stud while the motor is running at full speed. The motor can be overloaded or burned out, as the clutch can be tightened to a degree that will stall the motor. The speed of the driving spindle of the machine is variable and during the actual setting-up operation is only about one-third of the speed prevailing while the nut or screw is being driven down. The motor can be reversed by means of a special reversing control mechanism. (*The Iron Age*, vol. 110, no. 3, July 20, 1922, p. 146, 3 figs., *d*)

MARINE ENGINEERING (See Power-Plant Engineering)

METALLURGY (See Special Processes)

New Process for Mechanical Puddling. Description of an installation and process in an American plant (Titan Iron & Steel Co., Newark, N. J.). The principle of the process, which is the invention of Henry D. Hibbard, is in producing an intimate mixture of molten iron and oxide of iron by making the charge of the mixture pour repeatedly over a dam in a thin stream in an oscillating furnace.

The melting stage is carried on in a cupola from which the molten iron goes into the puddling furnace, where the operations of purifying, boiling and balling follow mechanically the hand method. Essentially, the furnace consists of a cylinder of steel plate about 6 ft. in diameter and 5 ft. 6 in. long with projecting trunnions 18 in. in diameter. The cylinder is lined with magnesite brick to an inside diameter of about 4 ft. The dam, which consists also of magnesite brick, extends up nearly to the center line. The operation is carried on at a temperature of about 2650 deg. fahr., the flame temperature (oil fuel) being 2850 deg.

As soon as the iron begins to form into a ball, the oscillating motion of the furnace is stopped and it is rotated clear over. The ball is carried to a squeezer, where it goes down through a passage of continuously decreasing dimensions and thence it is expelled in rough cylindrical form at the far side, free from surface slag and prepared for the breaking-down rolls. The iron is used largely for pipe and sockets, engine bolts, staybolts and high-grade merchant bars. Its physical properties are reported to vary in tensile strength from 45,000 to 52,000 lb.; elongation, 15 to 30 per cent. The original article gives some photomicrographs of mechanically puddled iron and a view of the installation. (*The Iron Age*, vol. 110, no. 3 July 20, 1922, pp. 143–145, 7 figs., *d*)

MOTOR-CAR ENGINEERING (See also Railroad Engineering)

10-Hp. Trojan Motor Car. This car, of British construction, has several unconventional features. The chassis may be described as a shallow box or tray, in and across which is mounted a two-stroke power unit and epicyclic gear, and at the corners of which are attached semi-elliptic cantilever springs supported at their free ends on tubular axles.

The engine has four cylinder bores arranged in a square in a single casting. It is, however, of the two-cylinder, two-stroke, three-port type, for each pair of cylinders has a common combustion chamber and a single spark plug. In each cylinder there is a three-ringed cast-iron piston with a long skirt and a plain head, the usual deflector employed in the majority of two-stroke engines being absent. The camshaft has two throws at 180 deg. The inlet pipe is taken to the center of the cylinder block and is led down between the cylinders where it branches into ports formed in each of the two lower cylinders. The opening of the ports is controlled by the difference of movement of the pistons due to the offsetting of the cylinders in relation to the crankshaft. As the pistons travel toward the top of the cylinders the mixture is drawn through the inlet port in the lower cylinder into the crankcase until the transfer port at the side of the upper cylinder is encountered, when it rushes through to the combustion space and is compressed there as the pistons ascend and draw in the next charge from the crankcase. As the pistons approach the top of this compression stroke, the mixture is fired by the spark plug in the upper cylinder. The upper piston is just behind the lower piston in its travel and there is a movement of the now burning mixture in the upper combustion chamber through the connecting port to the lower combustion chamber, so that turbulence of the gases is permitted right up to and during the period of combustion. As the pistons pass down the cylinders on the power stroke, the mixture in the crankcase is being compressed ready for transfer, and owing to the lead of the exhaust piston, the exhaust port in the lower cylinder is opened before the transfer port is uncovered. Thus the gas follows a circular path in its passage through the engine, for it enters at the base of the lower cylinder, passes through the crankcase, through the transfer port to the upper cylinder, thence to the lower cylinder, and out through the exhaust port.

The original article contains interesting details as to the lubrication and transmission system and it is stated that notwithstanding the use of solid tires, the riding in the car is comfortable. The body work is described as an "occasional" four-seater, for although four adults may be carried with ease, owing to the limitations imposed by wheelbase and the special design of the chassis as regards springing, the leg room is hardly sufficient for a long journey. (*The Autocar*, vol. 48, no. 1392, June 24, 1922, p. 1071–1072, 7 figs., *d*)

POWER-PLANT ENGINEERING (See also Steam Engineering)

Condenser-Tube Packing. Discussion of the subject, with particular reference to corrosion and crushing of tubes, and description of the John Crane flexible metallic-ring packing.

The author claims that corrosion is assisted by the insulation of the condenser tube from the iron shell by non-metallic packing, either at one or both ends, and that it may be reduced or eliminated

by bonding the tubes in good electrical contact with the tube sheets at both ends. It is said that the John Crane packing provides such a bond and in addition does not deform the tube at the point of packing contact.

In this particular device metal rings are used as packing material. These rings are built of many spiraled layers of very thin babbitt foil, so that while they are of metal they are also flexible and compressible. Each ring is die-formed so that it fits accurately the stuffing box for which it is intended.

In addition to this, special so-called expansion rings are used and each tube end requires two metal rings and two expansion rings, the expansion rings being apparently of fabric (asbestos). A special tool may be used for installing both types of rings. This tool may be of the hand-operated type for small condensers or of the pneumatic type for large condensers. (*The American Marine Engineer*, vol. 17, no. 6, June, 1922, pp. 25–31, 19 figs., *d*)

RAILROAD ENGINEERING

Gasoline-Driven Passenger Rail Cars

Some Recent Developments in Gasoline-Driven Passenger Rail Cars, W. L. Bean. An extensive paper covering the subject of design of gasoline-driven passenger rail cars. The general field of utility of this type of rolling stock is for short-line railroads where traffic is not sufficiently dense to pay for operation by conventional steam trains.

Self-propelled railway cars have been in use for a considerable number of years, but it is only quite recently that they have found extensive application.

The author believes that the gasoline engine may be the main type in use, although light-weight Diesel-type machines may offer competition, and even steam is not out of the running on self-propelled rail cars. While the gasoline mechanical drive is at present in the forefront, there is a renewed interest and endeavor to revive the gas-electric system along new lines embodying lighter construction and less power than formerly used.

Many railroad men have been extremely doubtful about the success of a single pair of wheels operating on rails at speeds necessary for passenger service. It can be stated, however, that the greatest success has resulted and over a sufficient period of time to demonstrate there is nothing to be feared in the trailing of a single pair of wheels under a car of this sort. It is not recommended, of course, that cars be operated at high speed in reverse motion, but even so, it has not been noticed that any difficulty has been experienced in backing six-wheel rail cars; the usual backing movements being under speeds of 25 m.p.h.

In further consideration of the six-wheel arrangement, it may be stated authoritatively that there is no advantage in using more wheels under a car which can be propelled by any of the existing automotive-truck power plants. However, in order to secure acceptable riding qualities in the rear of a six-wheel vehicle, it is desirable to have a wheel of a relatively large diameter; namely, 36 to 40 in., and arrangements to absorb shocks by rubber and other devices in connection with springs. Special consideration should be given to keeping the unsprung weight to the absolute minimum.

Very casual investigation of the operation of six-wheel rail cars shows low operating costs per mile. Cars built on two- to three-ton chassis will travel eight to eleven miles per gallon of gasoline, and cars built on five-ton chassis from four to six miles. The consumption, of course, depends on atmospheric temperature, length of run, loading, grades and especially speed. Maintenance should not exceed five cents per mile on the smaller car or eight cents per mile on the larger ones, over a considerable period of time. Other operating and maintenance costs depend on local conditions, particularly as to wages. One man is required for the mechanical operation of the car, but whether he can handle the collection of tickets and the performance of such other duties, depends altogether on local conditions, and each railroad man can figure that out for himself. First cost of a car of the smaller type is usually around $9000, and of the larger one, around $16,000, depending on the refinements of construction of chassis and body, and particularly whether or not the body is built for severe or mild weather conditions.

The use of self-propelled cars may be novel to railroad men accustomed to think only of trains containing a multiplicity of units, and an earnest study of the engineering problems of single self-propelled car operation is important, as it will lead to better development of this class of rolling stock.

While, under some conditions, trailer operation may become desirable, the need at present is to develop a real single unit within the limits of weight carried by two 4-wheel trucks. The author discusses in detail some of the engineering features involved, one of which is the relation between engine speed and car speed, especially from the standpoint of vibration; and also the comparative features of gear-driven and gas-electric types.

The problem of heating self-propelled cars is discussed and some data given on wind resistance, chiefly taken from previously known sources.

In the discussion which followed, J. C. Cain, manager of purchases, American Short Line Railroad Association, has given some of the figures on the cost of maintenance and operation, as follows:

"We were furnished records of cars that had made as high as 300,000 miles, and which had been in practically continuous service for a period of five years. The operating cost varied from 10 to 25 cents per mile, and gasoline consumption from 5 to 10 miles per gal.

"We found maintenance cost surprisingly low, averaging about $15 per month on these smaller-type cars, and only slightly above this on the larger ones. By smaller type I mean those using a two and one-half or three-ton motor-truck chassis, and by larger cars those using five-ton chassis. The operating cost of 10 cents per car-mile was, of course, confined to the former, which were being operated by one man. But some of the larger types using two men were being operated at as low as 20 cents per car-mile, as follows:

Gasoline	$0.030	per mile
Labor, 2 men at $125 per month	0.085	" "
Depreciation, rate 12½ per cent	0.042	" "
Interest and insurance	0.022	" "
Maintenance	0.021	" "
Total	$0.200	per mile

"These figures were made on a basis of $12,500 purchase price of the car, and an operation of 106 miles per day." (*Official Proceedings of the New York Railroad Club*, vol. 32, no. 7, June 19, 1922, pp. 6713–6726, illustr., and discussion pp. 6726–6744, *g*)

Diesel-Electric Motor Cars for Railway Service in Sweden. The first Diesel-electric car in Sweden, built in 1913, had an engine of 75 hp., but lately cars have been built of 160 hp. and 250 hp., both types being now in regular service.

Cars of 160 hp. weigh 37,500 kg. (82,500 lb.) and, when grades do not exceed 1 per cent, are capable of hauling a trailing load of 67½ metric tons (74¼ short tons) at ordinary speeds. This is a total train weight of 105 metric tons (115½ short tons). Cars of 250 hp. weigh 50,000 kg. (110,000 lb.) and under the same conditions can haul a trailing load of 115 metric tons (126½ short tons), which corresponds to a train of 165 metric tons (181½ short tons), including the motor car. Plain trucks are used on the engine-compartment end of these cars, and motor trucks, one motor for each axle, under the other end. The cars can be operated equally well from either end. With the passenger cars used in Sweden, which are much lighter than are customary on American roads, the 160-hp. car can haul a train with about 225 passengers, while the 250-hp. car can haul a train holding 375 passengers.

When hauling full trains the fuel-oil consumption for the 160-hp. engine should average about 0.7 kg. per train-kilometer or 2.5 lb. per train-mile, while the consumption for the 250-hp. engine should average about 1.0 kg. per train-kilometer or 3.5 lb. per train-mile. Oil records of a 160-hp. motor car for an extended period in regular service handling a train of metric tons (99 short tons) showed a fuel-oil consumption of about 0.5 kg. per kilometer or 1.8 lb. per train-mile. By weight, the fuel-oil consumption of the Diesel engines averages about 6 per cent of that of the coal used by steam locomotives of the same power.

The 160-hp. engine has eight cylinders and the 250-hp. twelve cylinders, but otherwise they are similar in general design to the

smaller engines. A number of improvements have, however, been introduced in the later designs of motor cars. The cooling water for the Diesel engines in now recooled in a number of radiators similar to those used for gasoline motor trucks, mounted on the roof of the car as shown in one of the illustrations in the original article. Cooling is effected by means of a fan blower driven directly from the main engine and is thus independent of speed. The motors are now arranged to be connected either in series or in parallel.

In addition to low fuel costs, one-man operation, and little time or attention required at terminals, experience has shown that Diesel-electric motor cars can make a greater mileage per day, spend less time in the shop, and run for much longer periods without a general overhauling than steam locomotives. They are capable of making 50,000 to 60,000 miles per annum. Even after being taken in for overhauling after some 60,000 miles, it has been found that the largest item of expense is for dismantling and reassembling.

While the Diesel motor car or locomotive will undoubtedly be still further perfected and adapted to a wider railroad field of usefulness, indications point to a much more general employment of this type of motor in the near future. (*Railway Mechanical Engineer*, vol. 96, no. 6, June, 1922, pp. 314–315, 2 figs., *d*)

The Steam Unit Car, E. S. French. Brief data on a self-propelled steam-driven car. The car weighs in the vicinity of 60,000 lb. and uses oil as fuel. The boiler is of a water-tube sectional design.

The main engine is of the two-cylinder piston-valve type. At 800 lb. pressure the mean effective steam pressure at cylinders is around 450 lb. Temperatures of superheated steam run from 450 to 800 deg. fahr. The speed of the engine is quite low. At 25 m.p.h. the engine makes approximately 270 r.p.m. and at 60 miles, approximately 890 r.p.m. The horsepower developed at maximum speed would be about 1000 hp. (*Official Proceedings of the New York Railroad Club*, vol. 32, no. 7, May 19, 1922, pp. 6745–6746, *d*)

SPECIAL MACHINERY

An Automatic Hot-Billet Scraper, R. C. Rohrabacher. The method now generally employed for removing surface defects on billets before they pass to the finishing mill involves the use of air hammers and chisels, which is expensive and unhandy.

The new mechanism is to be set up between two of the stands of rolls in the series, and another precisely like it installed immediately following the last stand of rolls so that the billets leave the second scraper machine ready to be finished into whatever final product the plant makes.

The mechanism comprises sets of stellite scrapers designed to engage the surfaces of the passing billets at whatever pressure may be required to remove the flaws, means being provided also for automatically guiding the billets to the scrapers. Pressure is applied independently to each scraper blade, each machine having four cylinders, two of which operate horizontally and two vertically. The apparatus may be operated under air, steam, or water pressure.

Stellite is used for the scraper knives because of its high degree of red-hardness. (*The Irom Age*, vol. 109, no. 17, Apr., 1922, pp. 1126–1128, 5 figs., *d*)

Hydroelectric Bloom Shear. A new type of shear has been developed for cutting hot blooms as they come from the blooming mill in plants driven entirely by electricity. The new element which makes it possible to provide a powerful hydraulic shear with the advantages in speed possessed by a steam-hydraulic shear is a motor-driven hydraulic intensifier.

Hydraulic pressure for the lifting cylinders and the gag cylinder is supplied by a separate hydraulic accumulator directly connected to them by pipes and at a constant pressure of 1000 lb. per sq. in. Low-pressure water for the intensifier and the main hydraulic cylinder is supplied from a prefiller tank under an air pressure of about 60 lb. per sq. in. This makes the whole water system a closed one in which the only water wasted is that lost by leakage.

Power to the intensifier is supplied by a flywheel motor-generator set to a direct-current shunt-wound reversing motor of 700 hp. with a full-load speed of 86 r.p.m. This motor, through a pinion and rack, operates a hydraulic ram with a working stroke of 14 ft. running in a cast-steel intensifier cylinder. The intensifier unit has a length of about 63 ft. overall. (*The Iron Age*, vol. 109, no. 16, Apr. 20, 1922, pp. 1078–1079, 4 figs., *d*)

SPECIAL PROCESSES

Calorization, Prof. Leon Guillet. The author discusses in a general manner the various processes for protecting against external chemical action of surfaces of metallic objects, in particular the process known as calorization.

He became interested in this process in 1915 when he was searching for a method of protecting in case-hardening the parts of the surface where it was desirable to preserve the original properties of the material. There were several methods considered, such as a clay coating, immersion of the article in a bath of sulphate of copper, deposition of metal by the Schoop process, and electrolytic deposition. All of these methods, however, proved unsatisfactory in one way or another and then calorization was resorted to.

It is of interest to note that the author obtained apparently satisfactory results by calorizing not only iron and steel articles, but also articles made of copper and copper alloys. He found, however (the same as in this country), that the calorized surface is very hard and unsuitable for machining, so that all parts of calorized objects must be machined before calorization. Moreover, calorization is an expensive process, especially on pieces of any considerable dimensions, and is entirely unapplicable to very large pieces, which makes it desirable to evolve some method for producing the same result by simpler means.

In this connection it is stated that in 1919 in Germany attempts were made to calorize grate bars on four freight locomotives of the Prussian State Railways by the Schoop process, and that the very first tests showed that the resistance of the grate bars so treated was four times that of untreated bars. Similar experiments on grate bars of express locomotives have shown that while non-treated bars have to be replaced every six weeks, none of the treated bars showed any appreciable signs of wear after a service of four months. Similar experiments are being carried out on a large scale in Denmark. One of the interesting features discovered in the experiments made in Germany is that clinkers do not stick to the treated grate bars, which materially reduces the work of cleaning fires. Alumino-treatment by the Schoop process is said to be much simpler, cheaper and of more general application than calorization. At the same time it requires probably the observance of certain precautions, and the author states that he knows cases where the aluminum layer peeled off. (*Bulletin Technique du Bureau Veritas*, vol. 4, no. 4, April, 1922, pp. 83–86, 3 figs., *deh*)

Wire Manufacture in England and France, Kenneth B. Lewis. A brief description of the processes used in Europe as compared with American processes, of particular interest because it shows the reason for the difference in practice in the various countries.

In the opinion of the author the British make better wire than the Americans, largely because in America a good deal of the wire produced by the wire-drawing mills is consumed by some finishing department of the same concern and the raw material, in this case, wire, can be made cheaper if the finishing department can make a product less accurately sized. In England, the wire maker buys finished rod and sells the wire, as, for example, to the nail maker. The latter demands first-class wire in order to maintain a high output from the nail machines, and the wire maker has to deliver such wire and insists on getting high-grade rod.

Furthermore, the wire drawer and the nail maker are 100 per cent unionized. They are on a piece-work basis, and if they do not like the raw material they get, they walk out.

The labor union is the outstanding factor in the industry from every angle. In conditions under which the American wire drawer handles four, five and even six blocks, the British wire drawer is permitted by the union to run only two. He has an abundance of time on his hands, which makes it possible for the boss to insist on a high degree of accuracy in the finished product.

The wire drawer is required to fix his own dies. He points his wire frequently with a hammer and anvil. The arrangement is crude and wasteful of time, but the wire drawer has time to waste.

In some mills the wire drawer must walk into the baker, pick up the bundle of rod on the floor and carry it in his arms to the bench—at that the rod bundles are small. The practice is apparently wasteful of time, but the wire drawer's time is paid for anyway and does not cost the boss anything for these particular operations. The expenses for improved machinery for production and handling of large bundles would fall on the proprietor, while all the profits would go to the union wire drawer, which is the reason for maintaining the current practice.

The British wire drawer is a highly skilled artizan. He serves a long apprenticeship and works his whole life at the bench. He knows instinctively how to vary his drafting and the shape of the die hole to suit the variations in the stock, and he does make beautiful wire.

British wire-drawing companies are old concerns firmly established, mostly family affairs. Consolidations are not usual, some of the reasons being psychological and others due to the difficulty of buying land that would be necessary for a consolidation involving expansion. There is practically no land held for speculative purposes. Land may be leased, but, generally speaking, cannot be bought, and people are reluctant to invest in a big undertaking on leased land. Furthermore, the established units of business are chiefly in congested districts and if they are to be brought together, it must be in a new place. If this should be done, it is an open question as to whether the workmen will follow the plant. The British workman does not care to change from place to place, and the British manufacturer cannot count on attracting to a new location a sufficient number of floaters. There are no immigrants in England, no great floating body of unattached young men ready to be shaped into skillful or semi-skilled laborers. The manufacturers can look only to the ranks of union labor. He cannot make wire drawers or nail makers. The union makes them and the boss takes them. (*The Blast Furnace and Steel Plant*, vol. 10, no. 6, June, 1922, pp. 323–325, *gc*)

SPECIAL PROCESSES

The Manufacture of Seamless Steel Tubes. Abstract from a recent issue of the *Ebbw Vale Works Magazine*, describing, among other things, the process used at these works.

Essentially this process does not differ from the standard methods, consisting of a piercing mill and a Pilger mill for rolling, the billet being then cold-drawn over a mandrel. (*The Iron and Coal Trades Review*, vol. 104, no. 2832, June 9, 1922, pp. 849, 1 fig., *d*)

STEAM ENGINEERING

High-Pressure Steam Generation

New Development in High-Pressure Steam Generation. Description of an experimental boiler designed for high pressure by the Power Specialty Co. and developed in coöperation with Thos. E. Murray, Inc.

The boiler is operated experimentally at 225 lb. pressure, but it is said that with slight modifications in structure it can be built for reliable operation at pressures up to 1000 lb. with the usual fluctuations in capacity required to be carried by modern single-service stations.

In this boiler the economizer delivers water to the boiler at approximately steam temperature, the boiler adding the heat of evaporation, and the steam is then led downward to the superheater on the rear furnace wall.

Each unit tube consists of two straight tubes rolled into a connecting member so as to form a hairpin shape from header to header, and the heating surface of the tubes is increased by means of "gilled rings" shrunk on the tubes. Each gilled-ring section contains five rings and by means of these rings the heating surface and the total heat transfer is increased to about six times that of the bare tube, in addition to which the shrunk sections increase the tube strength. A sealed spacing tube is contained internally and forces the water and steam into a thin annular path between it and the 2-in. tube.

Each section of the boiler receives water from a common horizontal drum and delivers steam through a vertical header into a horizontal drum. Water enters the lower end of each hairpin-shaped tube by means of a vertical water header. An equalizing pipe connects the vertical steam headers together. Since a small circular drum is much stronger for the same thickness of metal than one of larger diameter, the advantage of a large drum is obtained from a combination of small seamless structures, which are better suited for high pressure.

The relatively small boiler element absorbs heat at temperatures varying from approximately 2700 deg. fahr. to 700 deg. fahr. This produces a higher rate of heat transfer than in types with usual lower temperature of escaping gases, so that 90 per cent of the work ordinarily done by the boiler element is here accomplished with approximately 60 per cent of the usual heating surface.

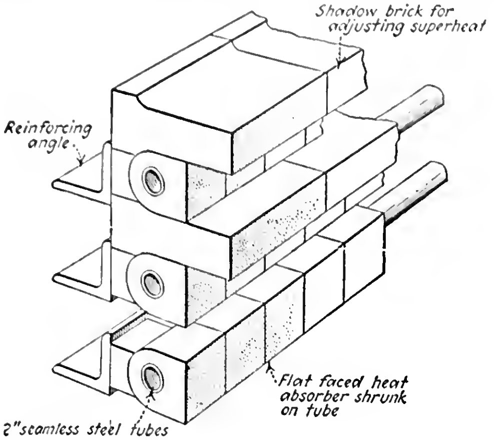

Fig. 7 Radiant-Heat Superheater Details

The economizer is composed of tubes similar to those of the boiler and has to be usually large as it is designed for entering gases of 700 deg. fahr. in order to produce feedwater close to steam temperature.

Water from the service pump at 100 lb. per sq. in., 80 deg. fahr. was employed in cleaning the heating surface once every twenty-four hours. This operation required ten to fifteen minutes and did not interfere with regular performance of duty, except in lowering the boiler-feed temperature for a period of less than one-half hour.

The Foster radiant-heat-element superheater is used, its advantage in this case lying in the fact that it is not affected by the weight of gas produced and therefore gives fairly steady superheat over a large range of capacity.

Fig. 7 shows a detail of shadow brick, tubes and flat-faced heat absorbers which are shrunk on the tubes. These produce 80 sq. ft. of heating surface. Reinforcing angles are bolted to these absorbers at intervals of 18 in. The amount of superheat may be adjusted by changing these shadow brick. The main blow-off valve is placed at the bottom of the superheater, while an auxiliary valve, adjusted for a higher blow-off pressure, is placed on the main boiler header. Piping is led from the economizer, making it possible to flood the superheater while the fire is being raised, or whenever required otherwise.

The original article gives results of two steaming tests. It is stated that the unit has been in service over an extended period, been tested under a large range in capacity, and is now in successful daily use with the other plant boilers at the Municipal Gas Company Plant, Albany, N. Y. (*Power*, vol. 56, no. 4, July 25, 1922, pp. 131–133, 4 figs., *dA*)

CLASSIFICATION OF ARTICLES

Articles appearing in the Survey are classified as *c* comparative; *d* descriptive; *e* experimental; *g* general; *h* historical; *m* mathematical; *p* practical; *s* statistical; *t* theoretical. Articles of especial merit are rated *A* by the reviewer. Opinions expressed are those of the reviewer, not of the Society.

ENGINEERING RESEARCH

A Department Conducted by the Research Committee of the A.S.M.E.

Research Résumé of the Month

A—Research Results

The purpose of this section of Engineering Research is to give the origin of research information which has been completed, to give a résumé of research results with formulas or curves where such may be readily given, and to report results of non-extensive researches which in the opinion of the investigators do not warrant a paper.

Aeronautics A1-22. Radiators for Aircraft Engines. Technologic Paper No. 211 of the Bureau of Standards, available for sale by the Superintendent of Documents, Government Printing Office, Washington, D. C., at fifty cents per copy, describes the laboratory investigations relating to aircraft-engine radiators which were conducted by the Bureau during the World War and in the two years immediately succeeding it. Individual reports covering many phases of the subject have been published previously by the National Advisory Committee for Aeronautics and in scientific and engineering journals. These reports, however, lack the systematic coördination, uniform terminology, and unified mathematical treatment which should characterize a handbook on the subject. Moreover, the problems which were investigated first because of their greater importance and which were the subjects of the earliest reports are for that reason not so well covered as is now possible because the later work has thrown much additional light upon matters not settled at the time of the publication of the earlier reports. Accordingly, the present paper is a revision and recompilation of the material available.

Refrigeration A1-22. Ammonia Tables. The Bureau of Standards has completed the measurements for a table of the thermodynamic properties of ammonia. The entire series of separate but correlated researches relating to the behavior of ammonia as a refrigerating agent has extended over a period of 8 years.

The results of the entire series of measurements are embodied graphically in a Mollier chart which was presented May 25 at the Detroit meeting of the American Society of Refrigerating Engineers. This chart is doubtless the only similar chart of thermodynamic properties of a working fluid for a heat engine which is based entirely upon actual measurements made in one laboratory, upon a fluid of a definite quality, in a program of separate investigations, each complete, each planned and executed according to a high standard of accuracy, and all extending over the entire range of conditions to be covered by the table. The resulting data have been made thermodynamically consistent, not by mutual adjustment of values or by arbitrary choice, as in the previous tables, but by perfection of experimental technique to the point where outstanding discrepancies are negligible. In this respect, the chart is unique in its class. It is now published merely as a preliminary edition, subject to revision.

Air A1-22. Compressed-Air Illness and Its Engineering Importance. Dr. Edward Levy, Consulting Physiologist, Bureau of Mines is the author of Technical Paper No. 285 on the above subject.

The effect of compressed air upon the life, health, and efficiency of workers in deep mining or subaqueous tunneling becomes of increasing importance in the study of occupational diseases and the medical problems of industries.

This report relates the experience of the author in curative and preventative work as physician to the Public Service Commission for the First District, State of New York, which supervised the building of the four pairs of tunnels constructed under the East River during the years 1914 to 1919.

Address the Superintendent of Documents, Government Printing Office, Washington, D. C. Price ten cents.

Electrochemistry A1-22. Generated Voltage of Cells at Low Temperatures. Scientific Paper No. 434 of the Bureau of Standards, for sale by the Superintendent of Documents, Government Printing Office, Washington, D. C., at five cents per copy, deals with the generated voltage of dry and storage batteries at low temperatures. The practical importance of a knowledge of the behavior of these two types of batteries at low temperatures has arisen from their use in the arctics and at high altitudes. Measurements were made on dry cells and storage batteries cooled to —72 deg. cent. (—98 deg. fahr.) by carbon dioxide snow and to —170 deg. cent. (—274 deg. fahr.) by liquid air. The Gibbs-Helmholtz equation was applied to the observations, and excellent agreement between theory and observation was found. At the lowest temperatures, high values of voltage were sometimes observed, and the polarity was often reversed. A possible explanation based on the Nernst equation is given.

Glue and Gelatin A2-22. The Chemistry and Technology of Gelatin and Glue. Dr. R. H. Bogue, who has been engaged since 1915 in research on gelatin and glue at the Mellon Institute, Pittsburgh, Pa., has completed a comprehensive treatise on The Chemistry and Technology of Gelatin and Glue. This work is being published by the McGraw-Hill Book Company, Inc. Dr. Bogue's consideration of the standardization of testing methods will be of interest to mechanical engineers. A brief account of Dr. Bogue's work appeared in the July, 1922 issue of the *Journal of The Franklin Institute*, pages 75–82.

Health and Sanitation A1-22. Compressed-Air Illness and Its Engineering Importance. *See* Air A1-22.

Industrial Management A1-22. Industrial Fatigue Research. A list of the topics discussed in the Annual Reports of the Industrial Fatigue Research Board (London) contains the following:

Hours of Work and of Ventilation, Influence of, on Output in Tinplace Manufacture (1919). With Illustrations and Statistical Tables. Price 0s, 6d.
A Study of Improved Methods in an Iron Foundry. (1919) Price 0s, 2d.
Fatigue and Efficiency in the Iron and Steel Industry. (1920) With Plates and Charts. Price 3s, 0d.
Adaption of Output to Altered Hours of Work, Speed of. (1920) With Plate and Charts. Price 1s, 0d.
Individual Differences in Output in the Cotton Industry. (1920) Textile No. 1. Price 0s, 6d.
A Statistical Study of Labour Turnover in Munition and other Factories. (1921) Price 3s, 0d.
Motion Study in Metal Polishing. (1921) (Metal No. 5). Price 2s, 0d.
Time and Motion Study. (Illustrated) (1922) Price 2s, 0d.
Address H. M. Stationery Office, Imperial House, Kingsway, W. C. 2, London.

Iron and Steel A3-22. The Nick-Bend Test for Wrought Iron. The "nick-bend" test is included in nearly all specifications for wrought iron. The usual statement says that the fracture of the nicked bar shall show no crystalline areas, or at least not more than a specified per cent. The clause, as usually given in American specifications, allows the nicked bar to be broken either by pressure or by blows. Foreign specifications of this test differ widely from American practice and from each other.

An investigation by the Bureau of Standards consisted in the fracturing, under known conditions, of nicked bars of 9 grades of wrought iron furnished by 5 different manufacturers. The composition, structure, and mechanical properties of the materials were determined, and the method of fracturing varied from simple transverse bending to severe impact, these extremes being permitted by current specifications.

A paper on this subject was presented at the June meeting of the American Society for Testing Materials, by Messrs. H. S. Rawdon and S. Epstein of the Bureau of Standards.

Light A1-22. Interference Methods for Standardizing and Testing Precision Gage Blocks. Scientific Paper No. 436 of the Bureau of Standards describes interference methods by which the planeness and parallelism errors of precision surfaces can be measured, and the length of standard gages can be determined by direct comparison with the standard light waves with an uncertainty of not more than a few millionths of an inch. The errors of other gages can be determined by comparison with these calibrated standards with equal precision. The process makes the standard light waves, determined to 1 part in 4 or 5 million, the standards of length for this work. The apparatus used for calibrating standards and comparing other gages with these standards is illustrated by line drawings and thoroughly explained. The paper may be obtained from the Superintendent of Documents, Government Printing Office, Washington, D. C., at ten cents per copy.

Panits, Varnishes and Resins A4-22. Carbon Black—Its Manufacture, Properties and Uses. This is the title of new Bureau of Mines Bulletin No. 192 by R. O. Neal and G. St. J. Perrott.

The authors point out in this paper that the present process of making carbon black recovers only a small percentage of the carbon in the gas, yet no other process in practical operation produces a material with properties similar to carbon black. Inability to secure carbon black would deal a serious blow to the printing industry, and inconvenience rubber manufacturers. On account of the diminishing supply of natural gas, development work should be conducted on more efficient methods of manufacture and production from other materials.

Carbon black is coming into extensive use in paints, since it has a higher tinting strength than any other black, consequently a given weight will obscure a greater area of surface.

Address the Superintendent of Documents, Government Printing Office, Washington, D. C. Price per copy twenty-five cents.

Petroleum and Allied Substances A8-22. Methods for Testing Petroleum Products. For a number of years a Federal Technical Committee made up of representatives of nine of the Government departments or bureaus

has been working on a set of specifications for petroleum products. This committee's work has been reviewed by the present Interdepartmental Committee on Standardization of Petroleum Specifications and its Advisory Board of seven representatives of the same number of civilian organizations, and has been finally adopted by the Federal Specifications Board. It is known as Bureau of Mines Technical Paper 305. This report covers specifications for gasoline, naphthas, burning oils, fuel oils, and lubricants. Address Superintendent of Documents, Government Printing Office, Washington, D. C. Price five cents.

Railroad Rolling Stock and Accessories A3-22. The Properties of Chilled-Iron Car Wheels. The scope of this investigation was revised and extended until it included tests to determine (1) the strains caused by mounting the wheel on its axle, (2) the strains caused by the static or wheel loads, (3) the ultimate breaking strength of flanges and strains caused by flange pressure, (4) the strains, due to temperature gradients in the wheel, caused by brake application, (5) incidental problems related to the above. Professors J. M. Snodgrass and F. H. Guldner, of the University of Illinois, conducted the experiments, on which this Bulletin No. 129 is based. In this work the University of Illinois Engineering Experiment Station had the coöperation of the Association of Manufacturers of Chilled Car Wheels.

The present bulletin gives the results of a series of strain-gage tests in connection with the items (1) and (2) just mentioned; that is, tests made to determine the strains produced within the wheel by mounting it on its axle, and by the application of wheel loads. The strain within the wheel caused by forcing it on an axle was first determined for two 33-in. 725-lb. M. C. B. wheels. The same pair of mounted wheels was then subjected to static loads ranging from 20,000 to 200,000 lb. per wheel, and the resulting strains noted. The loading effect was produced by applying the load to the axle by means of a testing machine, and allowing the wheels to transmit it to a pair of rails, the conditions being similar to those found in service. A similar set of tests was carried out with a pair of 33-in. 740-lb. arch-plate-type of wheels. Additional tests for the purpose of obtaining more complete information concerning the mounting strains were then made upon a pair of 33-in. 725-lb. M. C. B. wheels. The reporting of the results of the mounting and static tests upon the wheels just mentioned is the purpose of the present bulletin. It is intended to publish additional reports dealing with tests to determine the ultimate strength of flanges, the effect of flange pressure, and the effect of brake applications, together with the related problems of brake friction and the thermal expansion of cast iron. The report is fully illustrated and the data are shown in the form of curves and charts.

B—Research in Progress

The purpose of this section of Engineering Research is to bring together those who are working on the same problem for coöperation or conference, to prevent unnecessary duplication of work and to inform the profession of the investigators who are engaged upon research problems. The addresses of these investigators are given for the purpose of correspondence.

Automotive Vehicles and Equipment B3-22. Power Losses in Automobile Tires. The Bureau of Standards has undertaken a general investigation of automobile tires and inner tubes. In connection with this work a rather comprehensive program has been laid out for dynamometer tests, to study among other things the power losses or energy dissipated into heat in tires operated under different conditions of axle load, inflation pressure, speed, temperature, and tractive effort. Preliminary tests have been made to determine the influence of these factors, which, aside from matters of design, are the principal items affecting the power loss in a tire. A continuation of the work will involve problems of design and construction, the influence of "oversize" tires and of "cord tires" on power losses, mileage, and general efficiency of operation. An investigation will be made of inflation pressures as affecting the efficiency and economy of tire operation. Tests will be made to determine the effects of tire fillers, shields, puncture-proof tubes, etc., and the properties of cushion tires will be studied.

For copy of preliminary report known as Technologic Paper of the Bureau of Standards No. 213 by W. L. Holt and P. L. Wormeley. Address the Superintendent of Documents, Government Printing Office, Washington, D. C. Price five cents.

Corrosion B4-22. Corrosion of Metals by Acid Mine Waters. In the course of the general investigation of metal corrosion by mine water, being conducted by the Bureau of Mines at Pittsburgh, Pa., a study has been undertaken of the microscopy of corroded metals and alloys for the purpose of examining the preferential and differential corrosion of constituents in alloys under the action of different corroding media. The work will be done under the direction of R. J. Anderson, metallurgist, with the assistance of George M. Enos, research fellow. Address H. Foster Bain, Director, Bureau of Mines, Washington, D. C.

Ferrous Alloys. Magnetic Properties of Pure Alloys of Iron and Carbon. *See Magnetism B2-22.*

Foundry Equipment, Materials and Methods B4-22. Molding Sand. In coöperation with the joint committee of the National Research Council and the American Foundrymens' Association, the Bureau of Standards is investigating standard methods of testing molding sands. The formulation of the fineness test is practically complete, and the cohesiveness and other physical tests are well under way.

Fuels, Gas, Tar and Coke B2-22. Blast-Furnace Coke. Its Physical Properties. Investigations now being conducted by the Bureau of Mines at the Southern experiment station, Birmingham-Tuscaloosa, Ala., cover the physical properties of blast-furnace coke, including physical tests, solubility of coke in carbon dioxide, and analyses of blast furnace hearth gas. In the study of the reactivity of coke with carbon dioxide, the effect of mesh of coke, temperature, rate of flow of carbon dioxide, and dilution with nitrogen has been further investigated. Six furnaces have been investigated in the Southern district. Experimental work is being conducted also at the Pittsburgh, Pa., experiment station of the Bureau of Mines on the influence of fineness, medium, and time of boiling, in determining the true specific gravity of coke, which determination is used in calculating the amount of cell space or porosity of metallurgical coke.

Iron and Steel B2-22. Effect of Rate of Heating in Hardening Steels. The rate of heating for hardening has rarely been accurately regulated though it is apparently of considerable importance, at least in some steels and under certain conditions where control in dimensional changes in quenching is desired. This question is, therefore, of vital importance to manufacturers of die castings and in the production of thread gages. A series of 16 samples of chrome-vanadium die steel was hardened, using various rates of heating, and these dimensional changes noted. Unfortunately, the desired uniformity of results was not always obtained, but in view of the discrepancies found in other types of tests on the same steel, it is believed that the metal did not have the required uniformity. Similar tests of different steels will be carried out during the month and upon their completion further comments concerning these changes will be made. Address S. W. Stratton, Director, Bureau of Standards, Washington, D. C.

Iron and Steel B3-22. Resistance of Chromium Steels to Acid Corrosion. See *Corrosion B4-22.*

Magnetism B2-22. Magnetic Properties of Pure Alloys of Iron and Carbon. Experimental work has been completed by the Bureau of Standards on an investigation of the magnetic properties of a series of very pure alloys of iron and carbon. A number of alloys were prepared having carbon contents ranging from 0.018 to 1.60 per cent and containing no impurities in sufficient amounts to be of importance. Normal induction and hysteresis data were obtained for magnetizing forces up to 2500 gilberts per cm. and the results correlated not only with the carbon content but also with heat treatment. The reluctivity relationship previously used in the study of a carbon steel of eutectoid composition was found to be useful in correlating the results. A paper describing the results of this investigation is now in the course of preparation.

Metal Manufactures, Miscellaneous B1-22. Enameling of Metal Plates. During the past month the Enameled Metals Section of the Bureau of Standards has made an investigation of kitchen-ware enamels. About ten ground coats have been applied to 8-in. steel plates and coated with each of seven cover enamels, representatives of a series of enamels with varying composition. Some 600 plates have been enameled during the month. They are now being tested for resistance to impact, to thermal shock, and to acids, but the work has not yet progressed to a point where conclusions can be drawn. Some very interesting information, however, has been developed regarding the effect of variations in composition on the burning range, burning properties, and fish scaling.

Non-Ferrous Metals B2-22. Magnetic Determination of Iron as an Impurity in Brass. The presence of iron in brass is sometimes objectionable as it exerts a bad influence on the mechanical properties or interferes with cutting. For this reason, a rapid non-destructive method for its determination would be of value. In order to investigate the possibilities of a magnetic test in this connection, the Bureau of Standards has made a study of the magnetic properties of a series of samples of cast brass containing varying amounts of iron up to one per cent. It was found that the physical condition of the material as affected by heat treatment exerted a great influence on its magnetic properties, and that a quantitative determination, at least for the type of material investigated, is not feasible. There is no direct relationship between the magnetic properties and the carbon content.

Petroleum and Allied Substances B1-22. Temperature-Pressure Curves of Petroleum Products. In the course of investigations now in progress by M. B. Cooke, assistant refinery engineer, of the Bureau of Mines, into the nature of "gum-forming" constituents of gasoline, several gasolines and other petroleum products were heated in a small bomb, and pressures of considerable magnitude were developed. As the Bureau has received many inquiries for data showing the pressure that may be developed in a still when gasoline or other oil is subjected to elevated temperatures, it was thought advisable to record the pressures observed at various temperatures in the course of this work. These data were merely a by-product of the main investigation.

Gasoline and similar products are very complex mixtures, and it is difficult to determine accurately the true vapor pressures, hence the vapor pressures of the oils used in these tests have not been studied in detail, but the data obtained may be taken as representative of the pressure-temperature relations of the various oils in commercial work. Address H. Foster Bain, Director, Bureau of Mines, Washington, D. C.

Petroleum and Allied Substances B2-22. Oil Shale Investigations. At Boulder, Colo., at Salt Lake City and at Indiana University the Bureau of Mines in coöperation with the state institutions is carrying on intensive investigations into the best methods of distilling and refining the shale oil found in these localities.

Steel, Its Treatment and Products B5-22. Wear of Steels. Experiments have been started in the study of the rate of, or resistance to wear of, steels run in contact without lubrication. The Amsler wear-testing machine is being used for this investigation. The steels included in the preliminary studies form a series that has been submitted by the Gage Steel Committee and which is being studied in detail to determine the suitability of the steels for gages. In gage work, the question of wear is of extreme importance. Address S. W. Stratton, Director, Bureau of Standards, Washington, D. C.

Steel, Its Treatment and Products B6-22 The Mechanical Working of Invar. Invar steel, an important alloy where very low coefficient of expansion is desired, is very difficult to work mechanically. In order to see whether it could not be worked successfully, four small ingots of invar were prepared by the Metallurgical Division of the Bureau of Standards. The first attempt at forging was unsuccessful, the ingot cracking and breaking under the forging press. The second attempt was quite satisfactory as a result of very careful handling during forging operations.

It was found necessary to give very light reductions and not allow the forging temperature to drop below 1000 deg. cent. during the first reduction. This ingot was forged to a $^{3}/_{8}$-in. rod, and a portion of this was cut off and machined to a $^{1}/_{4}$-in. rod. This has been cold drawn with two intermediate annealings down to approximately $^{1}/_{16}$-in. wire. It is being carried further with the idea of determining how fine a wire of invar may be made.

Steel, Its Treatment and Products B7-22. The Effect of Manganese on the Magnetic Properties of Steel. It has been recognized for some time that manganese has an effect on the magnetic properties of steel which is of a somewhat similar nature to that of carbon. A series of iron-carbon-manganese alloys of exceptional purity have become available for a study of their magnetic properties. Several sets of specimens, each set having the same carbon content, but varying manganese, will be subjected to standard heat treatment and their magnetic properties determined. New apparatus for the testing of small specimens recently developed at the Bureau of Standards is being used in this investigation.

Steel, Its Treatment and Its Products B8-22. Effect of Rate of Heating in Hardening Steels. *See Iron and Steel B2-22.*

Ventilation B2-22. Relative Comfort Measurements by Means of Katathermometer. The katathermometer is an instrument contrived by Dr. Leonard Hill, an eminent English physiologist, and its various features have been fully described by him in his book entitled The Science of Ventilation and Open-Air Treatment. He made exhaustive experiments and concluded that the rate of cooling of the human body was the controlling factor in determining comfort or discomfort, and then set out to make an instrument that would measure this rate of cooling. The resulting instrument, the katathermometer, measures its own rate of cooling when its temperature approximates that of the human body and thus serves as an index of the rate of cooling of the body itself.

In connection with the coöperative metal-mine dust and ventilation investigations of the U. S. Bureau of Mines and the U. S. Public Health Service, some underground data have been obtained with intent to ascertain the adaptability of the katathermometer for determining the comfort of working places in mines. This preliminary study indicates that the instrument will probably be useful for making routine determinations of comfort conditions in our mines, and that it may also prove an important accessory for investigative work on problems in ventilation and kindred subjects in both coal and metal mines, although the instrument should probably be altered somewhat for maximum utility under the varied conditions in the mines of the United States.

By means of this instrument an exact numerical index of the relative comfort of a working place may be obtained, free from any personal equation, as determined by the temperature, pressure, relative humidity and motion of the air of the place. The instrument cannot take into consideration such vital elements affecting comfort as chemical impurity of air and presence of various kinds and quantities of dust, both of which may become determining factors in comfort of underground workers; nor measure the effect of undue noise, cramped positions, etc., which also may be important items in determining comfort of underground workers.

The authors of this Bureau of Mines Report of Investigation Serial No. 2355 are D. Harrington and G. E. McElroy. For further information address H. Foster Bain, Director, Bureau of Mines, Washington, D. C.

D—Research Equipment

The purpose of this section of Engineering Research is to give in concise form notes regarding the equipment of laboratories for mutual information and for the purpose of informing the profession of the equipment in various laboratories.

Chemistry, Industrial D1-22. The Mellon Institute of Industrial Research. The 9th Annual Report of Director Edward R. Weidlein has just been issued and serves as a reminder of the service which this institution is prepared to render industry through its system of Industrial Fellowships.

F—Bibliographies

The purpose of this section of Engineering Research is to inform the profession of bibliographies which have been prepared. In general this work is done at the expense of the Society. Extensive bibliographies require the approval of the Research Committee. All bibliographies are loaned for a period of one month only. Additional copies are available, however, for periods of two weeks to members of the A.S.M.E. These bibliographies are on file at the headquarters of the Society.

Aeronautics F1-22. Air Navigation, Theoretical and Practical. This bibliography in addition to giving a selected list of articles on aerial navigation contains selective references to allied subjects, such as Astronomy, Meteorology, Nautical Pilotage and Navigation, Cartography and Terrestrial Magnetism. Address Intelligence Branch, The Air Board, Ottawa, Canada.

Fluid Flow F1-22. Turbulent Flow of Fluids. This bibliography contains all the recent articles of importance on subject named in its title. It consists of two typewritten pages and is known as Search No. S. 3572.

Lubricants F1-22. Emulsification of Lubricating Oils. A bibliography of two typewritten pages. Search No. S. 3574.

Machine Parts F1-22. Gears. This is a fairly comprehensive bibliography of recent magazine and textbook articles on the subject of gears. It consists of five typewritten pages and is known as Search No. S. 3562.

Paints, Varnishes and Resins F1-22. Carbon Black—Its Manufacture, Properties and Uses This ten-page bibliography forms an appendix to Bulletin No. 192 on this subject recently issued by the Bureau of Mines. Address Director H. Foster Bain, Bureau of Mines, Washington, D. C.

Photography F1-22. Air Photographic Surveying and Mapping. The Intelligence Branch of The Air Board, Ottawa, Canada, has just completed three bibliographies on the general subject of aerial photography. One of them is named above and a copy may be secured by addressing the Air Board direct.

Photography F2-22. Forestry Reconnaissance and Forest-Fire Protection by Air. Address Intelligence Branch, The Air Board, Ottawa, Canada.

Photography F3-22. Air Photography, Generally. Address Intelligence Branch, The Air Board, Ottawa, Canada.

WORK OF THE A.S.M.E. BOILER CODE COMMITTEE

The Boiler Code Committee meets monthly for the purpose of considering communications relative to the Boiler Code. Any one desiring information as to the application of the Code is requested to communicate with the Secretary of the Committee, Mr. C. W. Obert, 29 West 39th St., New York, N. Y.

The procedure of the Committee in handling the cases is as follows: All inquiries must be in written form before they are accepted for consideration. Copies are sent by the Secretary of the Committee to all of the members of the Committee. The interpretation, in the form of a reply, is then prepared by the Committee and passed upon at a regular meeting of the Committee. This interpretation is later submitted to the Council of the Society for approval, after which it is issued to the inquirer and simultaneously published in Mechanical Engineering.

Below are given the interpretations of the Committee in Cases Nos. 365 and 396 to 405 inclusive, as formulated at the meeting of June 29, 1922, and approved by the Council. In accordance with the Committee's practice, the names of inquirers have been omitted.

Case No. 365

Inquiry: Is it permissible, under the requirements of the Boiler Code, to weld together the outwardly projecting edges of furnace door hole flanges by the autogenous process, provided the form of the circular door opening and the autogenous or fusion welding

is as shown in Fig. 19 and the staybolting around the opening does not exceed the permissible staybolt pitch as given in Par. 199?

Reply: It is the opinion of the Committee that a circular door opening, of the form shown, in which the projecting cylindrical portion of the inside sheet is provided with an outwardly turned flange, at its extreme edge, to form an abutment for the edge of the circular projecting flange of the outside sheet, and is made leak-proof by autogenously filling the space between these two flanges, will meet the requirements of the Boiler Code, provided the circumference of the outwardly turned flange on the cylindrical projection of the inside sheet exceeds the outer circumference of the flange of the outside sheet, and provided that the thickness of this cylindrical projection of the inside sheet conforms to the requirements of the following formula:

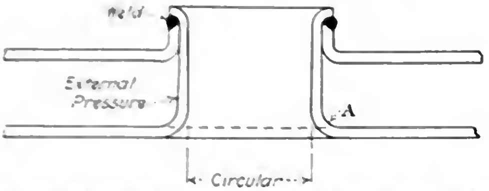

FIG. 19 CONSTRUCTION OF FURNACE DOOR OPENING WITH OUTWARDLY PROJECTING EDGES FLANGED AND AUTOGENOUSLY WELDED

$$P = \frac{5000 \times t}{R}$$

where

P = maximum allowable working pressure in lb. per sq. in.

t = minimum thickness of the plate forming the circular door opening in in.

R = the radius of the outer surface of the circular door opening in in.

Case No. 396

Inquiry: Is it permissible, under the requirements of Par. 257, to calk the heads of rivets? If so, how shall it be done and with what type of tools? Is it permissible to cut the plate or butt strap underneath the head and force the projecting metal up under the head?

Reply: It is the opinion of the Committee that it is permissible to calk the head of a rivet, if the rivet is not loose, provided the number of rivets requiring calking is not objected to by the inspector as indicating improper workmanship. Such calking must be done with a round-nosed or other type of tool which will not score or damage the plate under the head. The plate under the head should not be cut in order to force the metal up and make the head tight.

Case No. 397

Inquiry: Was it the intent, in Par. 199, to permit a value of 175 for C where copper washers were used as described in the definition for C?

Reply: It is the opinion of the Committee that the washers should be of steel to permit the use of 175 for C. Copper washers may be used provided no increase is assumed in the value of C for the strength of the washer.

Case No. 398

Inquiry: Is it permissible, under the requirements of the Boiler Code, to use a single-piece dome, with the shell drawn or pressed out of one piece, eliminating the lap seam and riveting of dome head to dome shell?

Reply: It is the opinion of the Committee that it was not the intent of the Code to prohibit the use of seamless construction otherwise built in accordance with the Rules.

Case No. 399

Inquiry: Is it permissible, under Par. 199 of the Code, to use a value of 175 for the constant C in the formula when the outside washer is omitted and instead an inside doubler plate securely riveted to the plate is used?

Reply: It is the opinion of the Committee that if three-fourths of the combined thickness of the boiler plate and doubler plate is used for the value of T in the formula, the value of 175 for C cannot be used unless outside washers are employed. It is the opinion of the Committee that if the thickness of the boiler plate is used for the value of T in the formula without adding anything for the thickness of the doubler plate, the doubler plate may be considered as the equivalent of the outside washer and the value of 175 may be used for C.

Case No. 400

Inquiry: Is it the intent of the Code that Par. 183, specifying the distance from centers of rivet holes to edges of plates, shall apply only to longitudinal joints, or is it applicable also to girth joints, manhole frames and other riveted attachments?

Reply: Par. 183 refers only to longitudinal joints.

Case No. 401

Inquiry: In Par. L-31, is it the intent that the area to be stayed is calculated from the maximum pitch squared, or the product of the actual pitches of the area supported by the stay under consideration?

Reply: The formula cited is based on the use of flat and not curved plates. In the absence of authentic data as to the reduction in stress that may be obtained due to curving the sheets, stayed curved sheets were made subject to the rules for staying flat plates. In the revision of the Code which is now under way, such allowances will be made for stayed curved plates in conformity with rules which have been developed since the last printing of the Code. For calculating the stress in staybolts the area of surface supported can of course be used. However, for spacing of stays or estimating stresses in stayed sheets, it will not be admissible to substitute the area of surface supported for p^2.

Case No. 402

Inquiry: Is it necessary, under Par. 195, where more than one manhole opening is inserted in a dished head, to increase the thickness of the head by more than $^1/_8$ in.?

Reply: It is opinion of the Committee that it is not necessary to increase the thickness of the head more than $^1/_8$ in. if more than one manhole opening is inserted, provided the minimum distance between the manhole openings is not less than one-fourth of the outside diameter of the head.

Case No. 403

Inquiry: Where a steam drum or dome is attached to a boiler, is this drum or dome to be considered a part of the boiler in applying the requirements of Pars. 277 and 278 for the attachment of safety valves?

Reply: It is the opinion of the Committee that where a steam drum or steam dome is attached to a boiler, the safety valve or valves, under ordinary conditions, may be located on this drum or dome. The area of the connection between the boiler shell and the drum or dome shall conform to the requirements in Par. 290.

Case No. 404

Inquiry: If a dished head is formed with a flattened spot or surface for the attachment of a connection or flange, is there any limit to the size of the plane or flattened spot on the head?

Reply: It is the opinion of the Committee that the diameter of the flat spot formed in the head should not exceed the value of p as given in the formula in Par. 199 or in Table 4, for the pressure and thickness of head involved.

Case No. 405

Inquiry: If a boiler constructed to the requirements of the A.S.M.E. Code for Boilers of Locomotives, is removed from the locomotive and operated for stationary or portable service, will the rules under which the boiler was constructed still apply?

Reply: The rules for the Construction of Boilers of Locomotives do not apply to portable locomotive-type boilers, such as are used for steam shovels, steam cranes, road rollers, and portable boilers used for threshing grain or cutting lumber.

If a locomotive boiler is removed from the locomotive and used in stationary or portable service, it shall be treated in accordance with Parts I or II of the Code for Stationary Boilers.

CORRESPONDENCE

Contributions to the Correspondence Department of Mechanical Engineering are solicited. Contributions particularly welcomed are discussions of papers published in this journal, brief articles of current interest to mechanical engineers, or comments from members of The American Society of Mechanical Engineers on activities and policies of the Society in Research and Standardization.

The Accuracy of Boiler Tests

To the Editor:

In the Accuracy of Boiler Tests, published in the July issue of Mechanical Engineering, Mr. Cotton's estimate of a plus or minus 3 per cent error in a "regular carefully conducted boiler test" is more or less justifiable according to what is meant by a carefully conducted test and particularly according to the length of such test. No doubt there are many boiler trials made, the accuracy of which is not closer than plus or minus 5 per cent. In fact a boiler test made with coal fuel never is and never can be accurate. Besides all the other reasons for this the difficulties of samplying and analyzing the fuel are sufficient.

While the author does not make specific recommendations toward the improvement of accuracy it is quite apparent from the paper, although not brought out very strongly in the discussion, that the primary requirement is a test of reasonably long duration. No duration however long will eliminate all of the errors but every added hour of the run, assuming uniform care and attention, reduces the proportion of total error. The one big error in a boiler trial is made when it is too short. A 48-hour run is in several respects more accurate than the average of two 24-hour runs.

The so-called heat balance is too useful to give up, but perhaps it would be wise to state only the computed items and their total as representing the "heat accounted for."

There are altogether too many boiler tests made and a large proportion of them are perfectly useless for many purposes. As pointed out by Mr. Burke, studies of temperature and flue-gas composition often give more reliable information than the evaporation. The writer recalls the instance of a coal-feeding device, the only function of which was to spread buckwheat coal over the grate. The merit of the device could have been determined by an experiment made 100 miles from any boiler and the actual tests made by using the machine under a boiler indicated several interesting things but only incidentally the functioning of the machine. It is extremely illogical and unwise to use a steam boiler as a measuring instrument. It lacks every desirable characteristic of such an instrument. It is costly, inaccurate and subject to all sorts of disturbing influences to say nothing of the human factor which always enters into its operation.

New York, N. Y. W. D. Ennis.

Test to Determine the Pressure Caused by Expansion of a "U"-Pipe Bend

To the Editor:

Recently the writer noted a request for information relative to the pressure exerted by the expansion of steam pipes when the pressure or strain due to the temperature is transmitted to the anchors.

Fig. 1 shows the method of test adopted by the writer to determine this. Preliminary calculations, however, were made as follows:

Pipe	standard full weight, 4 in. diam.
Wall thickness	0.237 in.
Sectional area of metal	3.18 sq. in.
Length of pipe in bend	23 ft.

Area in half section = 3.18/2 = 1.59 sq. in.
Lever arm of pipe = Y = O. D./2 = 4.5/2 = 2.25 in.
Lever arm of bend = 7 ft. 2 in. = 86 in.

Limiting the stress to 16,000 lb. per sq. in.

$$\text{Pressure} = \frac{16{,}000 \times 1.59 \times Y}{\text{Lever arm of bend}} = \frac{16{,}000 \times 1.59 \times 2.25}{86} = 665.5\text{ lb.}$$

This figure, however, does not disclose the number of inches of compression required to produce the stress which the test does show, as will be seen later.

The tensile stress in the pipe wall was calculated as follows:

	Sectional Area	Moment of Inertia
O. D. = 4.5	Outside = 15.904	I for O. D. = 20,129
I. D. = 4.026	Inside = 12.75	I for I. D. = 12.948
	Difference = 3.154	Difference = 7.181

Lever arm of bend	86 in.
Pressure to compress bend $2^3/_4$ in. from test	580 lb.

Whence

$$580 \times 86 = 49{,}880 \text{ in-lb.B.M.}$$

and

$$P = MY/I = (49{,}880 \times 2.25)/7.181$$
$$= 15{,}630 \text{ lb. per sq. in. tension in the bend.}$$

Fig. 1 shows the method employed in setting up for the test, which was as follows:

The bend was mounted on beam scales in such a way that only the load on the bend would be measured. Compensation was made on weight arm for the weight of the pipe and jack.

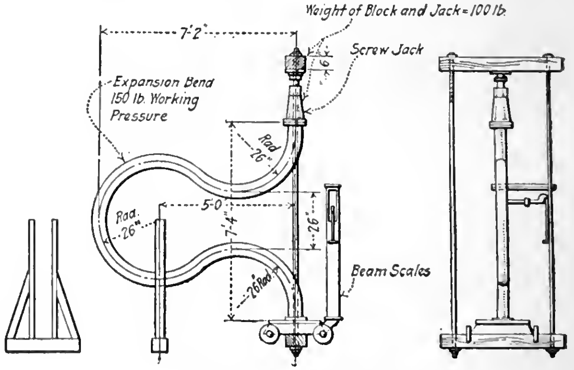

Fig. 1 Testing Device fo Expansion Bends

The compression test data obtained were as follows: The bend standing on a flange compressed $^1/_4$ in., due to its own weight, (255 lb.) and it required a pull of 49 lb. to restore it to its length of 7 ft. 4 in. between flange faces.

100 lb. compressed bend $^1/_2$ in. more, or $^3/_4$ in.
247 lb. compressed bend 1 in.
281 lb. compressed bend $1^1/_4$ in.
340 lb. compressed bend $1^1/_2$ in.
431 lb. compressed bend 2 in.
580 lb. compressed bend $2^3/_4$ in., or to 7 ft. $1^1/_4$ in.

As it is usual to stretch a bend of this kind when drawing up on the flange bolts, it may be assumed that there is little or no stress on the anchors except when cold, and that it requires approximately the same stress to extend the bend an equal number of inches, although this may not be strictly true, on account of the tendency to cripple the pipe wall on the inner radius and stretch it on the outer when the bend is made.

These tests were also intended to indicate the stress under ex-

pansion limits if the pressure was later raised to 325 lb. per sq. in. and at a temperature corresponding to this pressure and 150 deg. superheat; barring a possible decrease in the bursting strength of the pipe due to the temperature, the bursting safety factor for this pressure will be nearly 8 for 4-in. pipe and a cold-water test.

Baltimore, Md. A. E. Walden.

An Engineering Education Question

To the Editor:

The science of engineering in its various phases is the most powerful actuating lever in the world today as pertaining to the progress of civilization and the unfolding of known and unknown forces which will serve mankind, to the end that life as men now know it will only be remembered in the future as a nightmare of misdirected energy, waste, lack of order, and greed.

With the foregoing thought in mind, and those set forth in papers presented before the A.S.M.E. by Prof. C. F. Scott, T. C. Pratt, A. G. Christie, J. E. Otterson, and Dexter S. Kimball, on the subject of professional engineering education for the industries, the writer here records some impressions of the subject from the broad viewpoint of how to make the science of engineering most active in all the work of the world, for we want not only good engineers, and many of them, but we want—and must have—more men in the world's business who can engineeringly focus.

If so, how are we to stimulate a desire for engineering knowledge in our young men, and in the end produce the men with engineering knowledge, and in sufficient numbers to weave the thread of engineering science throughout the fabric of civilization in a symmetrical and predominating pattern.

It would seem to the writer that control as applied by our educational institutions to engineering education is the answer. We then may ask:

What is a sane and safe latitude for the control of an engineering education from the beginning to the end? A latitude which engineers, employers of engineers, and the public, can safely subscribe to as a means to the end of producing for America and the world the engineers upon whom will fall the task of carrying on the great development and progress, which must take place in national, civic, industrial, commercial, and transportation life as men push on to the world's greater future?

What kind of a system will best serve the universities of our commonwealth, to the end that they shall have the greatest opportunity of developing the greatest number of inventive, research, and constructive engineers?

What attitude will the educator, the engineer, and man of business take toward a means to the end of giving this country and its associates the greatest number of men who know what engineering means, and who, while not active as engineers, will think and act along engineering lines because of an engineering education?

Will educators sense the fact that an engineering course with latitude educates a man better than those leading to a L.L.B., B.A., or B.C.L., or like degrees, because it fits him better for any line he may follow in business life, and because it is obvious that the more citizens a country has who can think engineeringly, the greater and more rapid will be its advancement?

From the opinions which are appearing in the educational and technical press, it would seem that the prevailing idea on the subject of engineering education is that the harder and less attractive an engineering course is made, the better engineer it will produce. If such is the idea to be conveyed, it is eerie.

However, it seems that the majority of educators and engineers who are interested in the subject to the extent that they have something to say upon it, feel that the best results can be accomplished in the engineering course that calls for increased pressure and period—the kind of course which is most attractive to the photographic-minded student, because under a system of pressure and period it would only be the photographic-minded student who could hope to make the entrance, go through the course and be graduated, while the young man who absorbs knowledge slowly would have great difficulty in even approaching a university campus. Be it understood, however, that students with photographic minds can be developed into real engineers.

Under the plan suggested for improving engineering courses in order to produce better engineers, there is no provision made for considering the young man who may carry in his mind the rarest engineering ability, which ability cannot be cultivated by a system that assumes that the phenomenon of memory is a satisfactory proof of creative and constructive ability. However, this ability could be cultivated by a system based on time, reasonableness, patience, and encouragement.

The educational institution that would multiply the barriers to its engineering course so that only the so-called select students or high-grade men can enter, and by such barriers keep out all low-grade men, and then follow with an inflexible six-year course of study, is not rendering to America its maximum effort for the general good of the nation, and can be said to have reached the exclusive stage in education.

It is a fallacy to assume that the student who can reel off the day's work in perfect synchronism with the instructions of the professor is to be the great engineer of the future, because such is not always the case, as is shown by the history of engineers, past and present.

It may be that our educators and the engineers they have produced are developing a conviction that the profession of engineering will become debased if it is made easy to attain, but this is not so, and any line of reasoning which advocates pressure and ambition-killing periods for the young mind is wrong—wrong from a standpoint of efficiency as demonstrated through an engineering education, because efficiency in engineering as applied to the work of the world will best be served by our universities educating, or partly educating, all of the young men that it is possible to induce to take up the study of engineering. In this way there will be produced not only the greatest number of real engineers from the greatest possible field of embryo engineers but also, from the men who are not suited for the life of a working engineer, a class of non-active engineers who will find their place in the commercial world. These men will be properly educated to understand what constructive advancement means, and will be broader and more aggressive citizens, better servants of the government, state and municipal, better bankers, manufacturers and merchandizers. Again because they will know enough of the laws of engineering to make them interested in the evolution of the world along engineering lines, they will be able to help their brothers, the highly trained and natural engineers, to put into practice their ideas and aims and push civilization on more rapidly to greater heights.

It is a well-known fact that many 95 per cent men have proven "dudds" on the battlefield of engineering, and that many, yes—a great many class tail-enders, or dropped-for-failure men have to their credit great achievements. The first individuals had the photographic mind while the latter did not, and according to the education specifications proposed, would not have been accepted as students; nevertheless they have been able to meet the working specifications of the world through what they did assimilate engineeringly, and because of this they have accomplished things of importance. And let it be remembered that there are some brilliant engineers with concrete works to their credit who were not university trained, so that there is some power outside the pressure-and-period course suggested.

It would, therefore, seem that the engineers and educators of today should view this all-important question not from the standpoint that we must deal only with the easily educated young man, but rather from the standpoint that we wish to develop for our country, and the world, the largest number of engineers within our power, that we want to make engineering a democratic line of endeavor, not an exclusive one. To do this we must use the keys of reasonableness and encouragement, leaving the initiative and ambition of the student to act as the medium through which he will gravitate to his true position in life.

Chicago, Ill. W. R. Macklind.

A Correction

On page 516 of the August issue of Mechanical Engineering in Mr. T. A. Lewis's paper on Utilization of Waste Heat in the Steel Industry, the twelfth line should read "It amounts to $25,000 a year per furnace" instead of $2500.

Jurisdictional Board Asks Coöperation of Engineers

FOR over two years a quiet but effective body has been at work preventing misunderstandings that may lead to strikes in the building industry. These misunderstandings are not the major ones between the employers and the workmen but those insidious fallings out over work claimed by more than one building trade. In 1919, as the result of a plan adopted at the annual meeting of the Building Trades Department of the American Federation of Labor, a National Board for Jurisdictional Awards in the Building Industry was established. Coöperation of the contractors, architects and engineers was secured and as now organized this arbitration body is made up of three representatives of the labor unions, three representatives of contractors and employers of building-trade workers, a representative from the American Institute of Architects and one from the American Engineering Council.

The constitution and rules of procedure under which the Board has successfully carried on its work, provide, in the main, for the submission of complaints in writing through one of the organizations signatory to the plan, and a hearing after due notice to all parties in interest. A two-thirds vote of the Board is necessary for a decision, failing which, an umpire, whose decision is to be final, is selected either by the Board or the Secretary of Labor, although, thus far, it has not been necessary to resort to an umpire. Provision is also made for the appointment of committees to investigate cases that may be brought to the attention of the Board. Each of the labor bodies coming under the scope of the Board agreed that their membership shall not take up any sympathetic strikes in any case of jurisdictional dispute. Suitable penalties are provided for violation of this rule. Under the guidance of these principles the Board has considered a number of troublesome points of difference between the various building-trades unions and in general its findings have been regarded as final by the trade unions involved. In fact those who have been intimately connected with the workings of this Board are convinced that its accomplishments have fully justified its establishment. One prominent labor leader has expressed his satisfaction in a statement that the Board has accomplished more in the short period of its existence than the unions themselves in the years in which they have been joined in their Federation.

In only one instance has there been any organized attempt to obstruct the action of this Board. The carpenters refused to abide by the Board's award to the sheet-metal workers of the work of setting hollow steel doors, hollow metal window frames and sash. Great embarrassment resulted from the tactics pursued by the carpenters and as a result the carpenters' union was forced to withdraw from the Building Trades Department of the Federation. In a resolution, given in full in the June issue of Mechanical Engineering, page 405, condemning the action of the carpenters' unions of the Building Trades Department in disavowing its decisions, the Jurisdictional Board called upon all parties to the plan to show an active support, the architects and engineers by inserting in their specifications and contracts a stipulation that the decisions of the National Board for Jurisdictional Awards in the Building Industry shall be observed, the contractors by similarly requiring coöperation from their sub-contractors and the labor men by disciplining subordinate bodies that are inclined to dissent.

The attitude of the Building Trades Department of the American Federation of Labor is most encouraging, especially as at the recent Cincinnati convention it unanimously voted confidence and support of the Board's work. Furthermore it refused to readmit the carpenters' union to the Department except in accordance with the constitution of the Jurisdictional Board. There is, however, a feeling among some of the labor men that the architects and engineers are rather luke-warm toward this movement to eliminate jurisdictional strikes and that some of the contractors, among whom are many of our engineers, are not giving their support whole-heartedly. As their contribution to the elimination of waste in industry and as part of their obligations to their clients and the general public, who ultimately pay the cost of strikes and other labor troubles, engineers, both as designers and contractors, should line up with the other parties to this voluntary agreement and support with all their strength the work of the Board and use every reasonable effort to secure the coöperation of their colleagues and associates.

We take this opportunity, therefore, to emphasize again the request of the Board for engineers, architects and contractors to insert in contracts the stipulation that the decisions of the Jurisdictional Board shall be observed, than which no more direct or effective method seems practicable. It is not uncommon at the present time for architects and engineers to incorporate in their specifications that disputes as to the meaning of those specifications shall be submitted to arbitration, and even in many cases to name certain individuals in the specifications as arbitrators. Why is it not fitting that the success and standing of the Jurisdictional Board be recognized in a similar manner in matters pertaining to jurisdictional disputes?

Rudolph P. Miller.[1]

German Standards

THE writer had an opportunity to visit Germany a few months ago as a delegate of the American Engineering Standards Committee for the purpose of discussing international ball-bearing standards with the German Ball-Bearing Committee.

In this work I made the acquaintance of several of the leaders of the German standardization work and obtained an idea of the magnitude of this work in Germany.

It was only a few years ago that the "Normenausschuss der Deutschen Industrie," an organization corresponding to our American Engineering Standards Committee, was formed under the auspices of the Verein Deutscher Ingenieure, but the amount of work which it has accomplished since its formation is stupendous.

The "Normenausschuss" has already issued several hundred sheets of approved standards, and about twice as many are already published as proposed standards. This enormous output of the German organization has led many to believe that it was merely a factory, producing "paper standards," and that its work was not to be taken very seriously. A personal investigation convinced me that this is not the case, and I found that the great output of standards was merely due to the enormous efforts put forth and to the enthusiasm of the great majority of the interested parties.

---

[1] Representing American Engineering Council on the National Board for Jurisdictional Awards in the Building Industry.

This enthusiasm is due to a more or less general recognition, created under the pressure of war conditions, of the great economical value of standardization, and to the very generally accepted opinion that a standardised industry would be one of the strongest weapons in Germany's struggle for economic rehabilitation and financial reconstruction.

To give a concrete illustration of this point, I may mention that at the time of my visit, a syndicate of nineteen German and one Swedish manufacturer was executing an order for seven hundred locomotives for Russia, all of the same design, and every part in every one of them was being made interchangeable with the corresponding part in all the others, all parts having been manufactured to the same fits and tolerances. This feature will have the great advantage of permitting the Russian railroads to use any disabled locomotive as a store of spare parts for all the others. In case of future orders, the Russians will no doubt specify that all new locomotives of this class be built not only of the same design as above, but so that every part is interchangeable with the above.

Another error in our conception of German standardization is that the "Normenausschuss" is autocratic in its methods and is not in as close contact with the industries as our own standardizing bodies. I found, on the contrary, that absolutely the same methods are used there as here to arrive at national standards. The staff of the "Normenausschuss" is merely coördinating and directing the work of the various committees, and the actual establishment of standards is left to recognized leaders in the various industries.

The work of the permanent staff is greatly facilitated by the eager response from German industry, whose leaders look to standardization as one of their greatest hopes for salvation. Many of the big German manufacturers have standard departments of their own, with a number of engineers and draftsmen working permanently on national standards.

It would of course, be highly desirable to establish international standards and great efforts are being made to obtain them in certain lines, such as ball bearings. One of the greatest obstacles for international standardization, however, is the fact that America and England do not commonly use the same scheme of measurement as other countries.

There is no doubt in my mind that one of the main reasons why forward-looking Germans force their standardization work is because they want to impress German standards on the great import countries and possibly on the whole world. Holland, Switzerland, Austria, Sweden and many other European countries follow the German lead very closely. The great German deliveries in kind to France will no doubt, as far as feasible, be made according to German standards, thereby introducing them in that country.

The days may not be far distant when our manufacturers will receive inquiries from oversea countries to furnish goods according to the national German standards or specifications, as referred to above in connection with the Russian locomotives, and it behooves us to plan in time to meet such conditions. England seems to have fully realized the importance of recognition of her standards, and is trying to force the adoption of them in her colonies and dominions.

Another institution closely connected with the "Normenausschuss" deserves special mention, and that is the Committee on Industrial Processes. This committee investigates the methods used in the various industries to obtain certain results, submits them for critical comparison and standardizes the best obtainable methods. This committee, which is also sponsored by the Verein Deutscher Ingenieure, works of course in very close coöperation with the "Normenausschuss."

On account of its very efficient organization, the German "Normenausschuss" has come to play a more important role in the industrial life of the nation than originally expected. Manufacturers write to it for advice on questions of the most delicate nature, and frequently competitors exchange manufacturing secrets through some member on its staff.

In conclusion I wish to express the hope that the example of the German engineers and manufacturers may spur us to make equally large contributions in work and money to the cause of standardization, and that our leading engineers may try to realize the enormous economical importance of both national and international standards.

Oscar R. Wikander.

Beneficial Effect of Prizes

THE A.S.M.E. Committee on Awards and Prizes has been asked to write briefly as to the benefit to the Society and to Engineering of the prizes and honors which are in the gift of the Society, with the idea that it might possibly arouse greater interest in the subject and induce a larger number to compete for these awards.

The idea of the award of a prize for the greatest merit must be practically coeval with the race. Not many of us as engineers have read the poem in the original, but we all know that one of the greatest of the world's poems, the Iliad, was in a way the result of the award of a prize in a beauty contest. Leadership in savage tribes is the reward for supremacy in bravery, skill at arms or wisdom, and so we might go on indefinitely. In other words, the feeling seems thoroughly implanted in human nature that some tangible evidence of recognition of superiority is of great value in helping to bring about that superiority.

In considering the award of prizes by our Society there comes to mind the story told of Herbert Spencer, the great philosopher (who was at first an engineer), which, whether true or not, is worthy of very careful consideration. It is said that after he became famous and was recognized as one of the world's greatest philosophers, the universities of Oxford and Cambridge offered to confer on him the honorary degree of Doctor. The story goes that Spencer's reply was that, when he was a young man and struggling hard to get recognition for his work, and when such degrees from the universities would have been of great value to him, they were not forthcoming; now that he had attained a certain degree of fame without their help he objected very decidedly to having the universities plaster their label on him after all the rest of the world had already assigned him a definite position. Observation of the honorary degree lists of our own great universities would lead one to believe that in general they follow the same plan as the English universities followed with Spencer. In other words, after a man has become famous then the universities acknowledge that fact by giving him a degree. Nevertheless Spencer's declination of the honor is about the only one on record.

This does suggest, however, that the Society might very well take the lesson to heart, and endeavor to ascertain meritorious work whether the individual is already well known or not, and that in the case of previously unknown men this award of approbation would have a real value, and might, in many cases, be such an encouragement as to lead to work of the highest value later on in life.

In order that this may be the case it is necessary that all the members of the Society should take an interest in the subject, familiarize themselves with the awards which are provided and assist the Committee on Awards and Prizes by friendly suggestion, where they are not competitors themselves, and by doing their own very best work where they feel that their efforts may justly entitle them to consideration.

An annual prize is for the best paper appearing in the Society's Transactions during the year. These papers cover so wide a range of subjects that it is impossible for a single committee unaided to make a decision based on expert knowledge of these many subjects. If the members who specialize in any particular subject find a paper along their specialty which commends itself to them as of very high value it would be a favor to the Committee and helpful to the Society if they would write to the Secretary's office giving their opinion, together with the reasons for esteeming it of specially high value. The Committee can then be trusted to weigh the evidence in the various cases and make a decision, taking account of all the features which enter in such a competition, with the probability that the paper finally decided upon is undoubtedly the best of all which appeared.

With respect to the medal for specially meritorious inventions or work in engineering, it may well happen that some members may know of such cases, which, unless they advise the Committee about them, might pass unnoticed. This was exactly the case with the first award of this prize. Those who knew of the work of Mr. Carlson recognized that it was of extreme value to the country in its hour of trial and that it solved a problem which otherwise would have involved immense cost and difficulty.

The Committee believes that much greater honor will accrue to the Society from the discovery of highly meritorious work of obscure

or little-known members. rather than from conferring the prize on some famous men whose work has been heralded in the daily press until it is known to every bright schoolboy.

The Committee on Awards is willing to do a great deal of work and give its very best efforts to advancing the interests of the profession in making suitable recommendations, but it lays no claims to omniscience and must have the cordial coöperation of the membership at large if the great benefits which will result from the proper award of the prizes is to be secured.

Walter M. McFarland.[1]

Alfred D. Flinn Reports Nationwide Interest in Research

Alfred D. Flinn, secretary of the Engineering Foundation and chairman of the Division of Engineering of the National Research Council, returned August 2 from a six-weeks' tour to the Pacific Coast on which he addressed groups of engineers to enlist their aid in a nationwide plan for engineering and industrial research.

Mr. Flinn addressed meetings at Salt Lake City, Los Angeles, San Francisco, Sacramento, Portland, Oregon, Seattle, Duluth and Minneapolis. In spite of the fact that the time of year was such that the men of the profession were to a large extent scattered, a group of from fifty to seventy-five representative engineers were present at every meeting. The meetings were arranged by local sections of the National Engineering Societies, or the local engineer's club, and the audiences included officers and members of these Societies as well as others interested in problems of research.

There was evidence of interest everywhere in the work of the Engineering Foundation and the National Research Council. Men were impressed by the extent and quantity of the work already done, considering the limited resources of the Foundation, and desirous of having the work pushed further so they could have the benefit of it. The Engineering Societies Library received favorable comment for the splendid service it renders to engineers.

At Los Angeles, San Francisco, Seattle and Portland Mr. Flinn found particular interest in the proposed study of arched masonry dams. In the first three of these cities there was an active interest in the marine-piling investigation being conducted by the National Research Council. In this connection, during Mr. Flinn's time in Canada where he met and talked with individuals instead of groups, he met Prof. C. McLean Fraser of the Biological Board of Canada. Professor Fraser gave assurance of his desire to coöperate in the study of marine borers and estimated that the damage done by these small animals to the wooden piling along the British Columbia Coast alone amounts to several hundred thousands of dollars every year.

One object of the trip was to make personal contacts that might lead to interesting people of means in contributing to the support of the Engineering Foundation. Engineers themselves are not able to do this and contributions must come largely from outside sources. Personal contacts were also made with men who can be useful in committee work and who have shown a desire to help.

St. Louis Central Station to Use Pulverized Fuel

Mechanical engineers who have been following the performance of the powdered-fuel installation at the plant of the Milwaukee Railway and Light Company will be very much interested in the announcement that the new Cahokia plant of the Union Electric Light and Power Company, St. Louis, Mo., is also to have a pulverized-fuel installation.

In a statement recently issued, McClellan and Junkersfeld, Inc., engineers and constructors of this project, emphasized the fact that in the Cahokia plant pulverized-fuel equipment will permit the economical use of the low-grade Illinois coal having a heat value of approximately 10,000 B.t.u. per pound and high moisture and ash contents.

The decision of the engineers was reached after extensive tests and investigation on stokers and pulverized-fuel equipment. The plant at Milwaukee afforded an excellent opportunity for the investigation of performance with powdered coal and it placed the results on a basis comparable with those secured with the best modern automatic stoker plants.

The new plant, of which 60,000 kw. will probably be in operation next year, will have an ultimate capacity of 240,000 kw., and is to supply the rapidly increasing industrial and lighting load in St. Louis, in addition to that now being supplied from the Keokuk Dam and from an existing large steam plant.

The engineers state that improvements may be expected in the development of stokers as well as in pulverized-fuel equipment but that stokers have been under development for a long period of years, and the burning of coal in pulverized form in large quantities by central stations has been done only in the last few years. Without attempting to estimate future developments in the two classes of equipment for burning coal at least the present relative position, so far as the Cahokia Station is concerned, will probably be maintained.

The engineers call particular attention to the fact that their recommendation should not be applied to any other quality or price of fuel, plant site, plant layout, load factor or other conditions without making careful adjustment for the differences between such conditions and those which obtain with the Cahokia Station.

Two 30,000-kw. turbines, eight 1800-hp. B. W. boilers without economizers and a Lopulco system for burning pulverized fuel will be installed. The plant will be located on the Illinois side of the Mississippi River about fifteen miles from the coal mines.

DeLamater-Ericsson Collection to be Nucleus for National Museum of Engineering

At the Council Meeting in Atlanta on May 8, President Kimball announced the appointment of five A.S.M.E. representatives on the Joint Committee on the DeLamater-Ericsson Historical Collection. The personnel of the Joint Committee is as follows:

American Society of Mechanical Engineers: H. F. J. Porter, Chairman of the Committee, Sydney Bevin, Fred A. Halsey, Thos. F. Rowland, Jr., Henry R. Towne; Swedish Societies of New York: Axel S. Hedman, Johannes Hoving, Charles K. Johansen, Emil F. Johnson, Ernst Ohnell; Associated Veterans of the DeLamater Iron Works: Walter M. Parker. This Committee will collect the historical material connected with Cornelius H. DeLamater and Capt. John Ericsson during their fifty years association as the leading factors of the DeLamater Iron Works.

In the concluding paragraph of the Report of the National Museum at Washington for 1920, attention is called to the fact that "the commanding place in the world which the United States has reached in the short space of seventy-five years is due largely to the full development and utilization of mechanical power in the exploitation of her natural resources. It is this that has made it possible for the people of the United States to enjoy a standard of living far and above that under which the peoples of the rest of the world exist, and still no public sign of appreciation, either national or otherwise, is to be found anywhere. What more suitable monument could there be than a Museum of Engineering and where could there be found a more logical place for it than as a part of the great National Museum?"

The Smithsonian Institution then not only solicited the placing of the DeLamater-Ericsson Historical Collection in its National Museum but proposed the coöperation of the Committee in establishing the nucleus there of a great national engineering museum comparable to the foreign museums to record the accomplishments, in the upbuilding of this nation, of its engineers. The DeLamater-Ericsson Historical Collection will be exhibited first at the Annual Meeting of the Society in December. Later such part of it as will exhibit the contribution to civilization by the Swedish-American engineer, Captain Ericsson, will be sent to Sweden to the Tercentenary of Gothenburg to be held there from May to September, 1923. On its return, the whole collection will be placed in its permanent repository in the Smithsonian Institution in Washington, as the nucleus for the Engineering Section of the Museum.

It is desired to make this a national movement in which every engineer in the country will participate. Engineering societies and alumni associations of engineering schools are requested to communicate for further information with the Joint Committee on the National Engineering Museum, 29 W. 39 St. New York, N. Y.

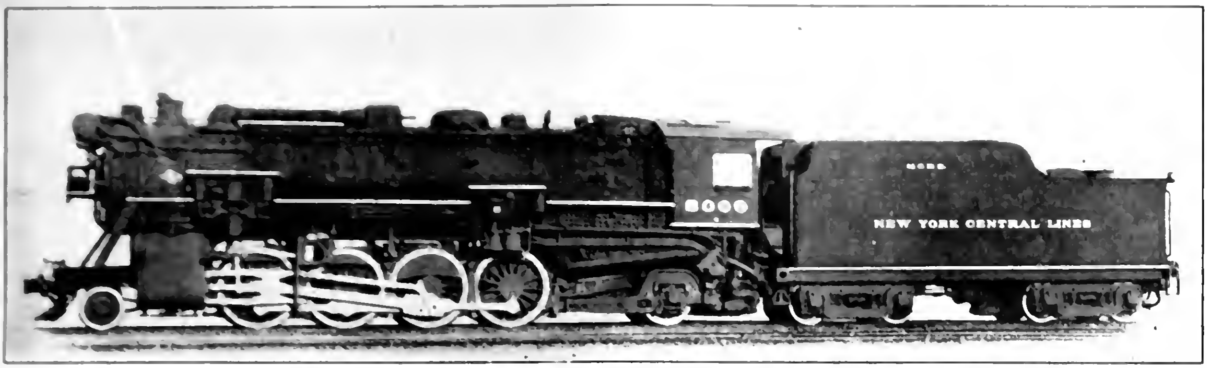

Fig. 1 The Novel Attachments, Shown Above, Contribute to Economical Operation

Remarkable Steam Locomotive Sets New Standard

Mikado for Heavy Fast-Freight Service on the Michigan Central Embodies New Devices and Principles That Insure Light Weight and High Economy

REGARDLESS of the gesture threatening electrification of railroads sometime in the future, the development of steam locomotives goes merrily on. The most recent example of remarkable progress is a new Mikado placed in heavy fast-freight service on the Michigan Central a little over two months ago. This machine embodies the results of a score of years of study and research and although no official tests have been taken, the performance has been so satisfactory that the order has been placed for one hundred and fifty according to the same detail specifications. In its initial road test, it hauled 100 heavily laden coal cars and later pulled a train of 140 cars containing more than 9000 tons of coal, this over the level division between Toledo and Detroit.

"No. 8000," as this extraordinary engine is designated, was built by the Lima Locomotive Works according to designs made under the supervision of President A. H. Smith of the New York Central Lines. To obtain a drawbar horsepower for the minimum fuel, weight and cost of repairs and to secure ease and safety of operation, the best known practices and devices have been incorporated.

The first requirement of maximum tractive effort for the minimum weight is an elimination of unnecessary weight and this has been accomplished, without sacrifice of strength, by refinements in design and by the use of alloy steels and hollow axles and crank pins. Without tender, the locomotive weighs 334,000 pounds The tender with its capacity of 10,000 gallons of water and 16 tons of coal, weighs 199,700 pounds. Maximum tractive effort of 74,500 pounds is obtainable, a booster on the trailer truck delivering 11,000 pounds. In a statement issued by the New York Central Lines, quoted recently in the *Railway Age*, attention is especially directed to the fact that, comparing No. 8000 with the heaviest Mikados in the Michigan Central service, No. 8000, with an increase in weight of only two per cent, has an increased tractive power of nearly eight per cent from the forward cylinders alone and with the booster cut in the increase is 26 per cent.

Fig. 2 The Feedwater Heater is Prominent

Perhaps the most noticeable change in this locomotive to achieve greater economy in fuel consumption is the addition of a feedwater heater. In the use of superheated steam a departure from common practice is the location of the throttle between the superheater and the cylinders and the use of superheated steam in the air pump, feedwater pump, booster engine and headlight turbo-generator. In Fig. 1 the dry pipe can be seen leading forward for connection with the superheater. The throttle box is ahead of the stack, an arrangement necessary for the use of superheat in the auxiliaries. A double arch, with eight supporting tubes, increases the effectiveness of the fire and improves the boiler circulation.

The feedwater heater is installed at the front of the engine over the headlight, high enough to return the condensate to the filter in the rear of the tender. The feedwater pump is shown on the left side of the locomotive. The boiler pressure is 200 lb. per sq. in. and the superheat at the cylinder is over 550 deg. fahr. The Type E superheater, using superheater tubes in every boiler flue, was applied. The cylinder diameter is 28 in. and the stroke is 30 in.

The cab design is such that the enginemen perform their duties with the minimum of movement and practically no physical effort. Precision power reverse gear, an Elvin stoker and a power grate shaker are installed for this purpose. The whistle is operated pneumatically. There is a water scoop on the tender.

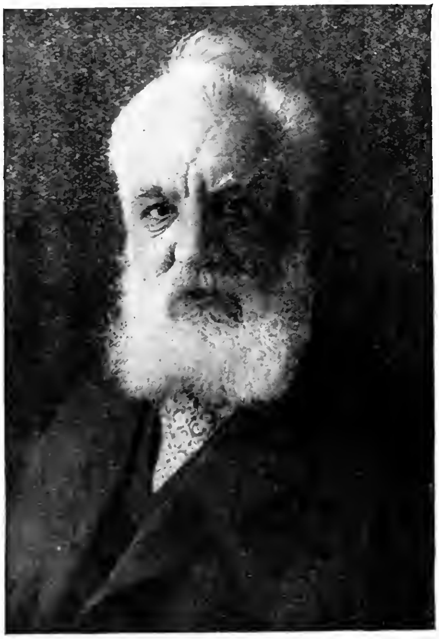
For many years, the development of steam locomotives was in size and weight but without systematic improvement in the making and using of steam. With the adoption of superheat, economy of operation was greatly improved but steam-locomotive design is still under great pressure to meet rigid requirements with definite limitations of size and weight and at the same time to equal the best results of marine and stationary practice. In this respect No. 8000, an embodiment of devices not new or radical, sets a new standard. Further, the elimination of weight and the refinements of design will lessen the dynamic augment

Steam locomotives must bear the burden of transportation in this country for some time to come and the development of this machine is a courageous movement toward better practice. The old rule demanding simplicity above all seems to have been discarded.

Alexander Graham Bell, Father of the 'Phone, Dies

ALEXANDER Graham Bell is dead. In the early morning of August 2, 1922, the great inventor passed quietly away at his summer estate in Nova Scotia. At sunset a few days later his body, clad in a homely tweed and corduroy suit similar to the one he wore in his laboratory, was laid to rest at the peak of Beinn Bhreagh Mountain overlooking the beautiful Bras d'Or lakes on whose waters he had experimented with speed boats and fast water sleds.

The inventor of the telephone was born in Edinburgh, Scotland, March 3, 1847. His grandfather, Alexander Bell, invented a system for overcoming stammering, and his father, Alexander Melville Bell, dean of British elocutionists, perfected a system of "visible speech" by which the dumb could speak. Young Bell was educated at Edinburgh and London where he acquired a smattering of music, electricity and telegraphy. His chief interest lay in the study of sound, and at the age of sixteen he was teaching elocution in the British schools and instructing deaf mutes.



Alexander Graham Bell

At twenty-two Bell was threatened with tuberculosis, a disease which had claimed his two brothers. His whole family migrated to Canada in 1870 and the next year he went to Boston University as professor of vocal physiology. His system of teaching deaf mutes won immediate recognition and his success encouraged him to open a school of his own. He went to live at the home of one of his pupils in Salem, and it was in the Sanders cellar after school hours that he started a series of inventions that were to culminate in the telephone.

In the winter of 1874, at an electrical workshop where he had taken his "harmonic telegraph," a device for sending a number of Morse messages over a single wire at the same time, Bell met Thomas A. Watson, who was employed there. From that hour Watson devoted most of his time to working out in brass and iron the ideas that came pouring out of Bell's brain. The two young men labored day and night in the workshop and in the Sanders cellar in Salem to demonstrate Bell's dream that an electric wire could carry the sound of the human voice. They worked while sane men gaped at them in pity.

In June, 1875, after months of experiments on the harmonic telegraph, something happened to convince Bell that at last he was on the right track. One of the transmitter springs of his telegraph instrument stuck, and the magnetized steel generated a current that sent a faint noise over the electric wire to Bell's receiver. This was the necessary proof that his principles were correct. Thereafter it was a question of working out details. On March 10, 1876, at a Boston boarding house, Bell, from his room on the top floor, spoke to Watson in another room, and Watson heard what was said. A week later Bell took out his first patent on the telephone.

The invention of the telephone was unique in a special sense in that it had not even been foreshadowed before its achievement. In later litigation on the Bell patent, the literature of the world was searched without finding a hint that anyone prior to Bell had even a vague thought as to how the electric transmission of speech could be effected. Possibly it was just this very fact that threw such stupendous financial difficulties in the way of the young inventor. The press reflected universal scepticism, and funds ran low for many months.

The story of the exhibit of the telephone at the Philadelphia Centennial Exposition on the day set aside for "freak novelties" has often been told, but not always in quite the way that Bell himself told it. According to Frederick P. Fish, former president of the American Telegraph and Telephone Company, to whom Bell repeated the story, the exhibit of the telephone created little attention. The various freak novelties were to be presented in order and the telephone appeared far down on the list. Sir William Thompson (Lord Kelvin) was to be present at the exhibition, and Bell was much excited at the prospect of having this eminent scientist see his invention. However, on the day of the exhibit, Sir William was delayed until it became so late that Bell thought his golden opportunity had been lost.

Finally Sir William came, and with him Dom Pedro, the Emperor of Brazil, a man of high attainment and very much interested in every phase of scientific work. Although Dom Pedro had once met Bell in connection with his work in teaching the dumb, Bell had no idea he would be remembered. But Dom Pedro grasped him cordially by the hand and when told of the invention of the telephone, asked to have it exhibited first of all. Both Sir William Thompson and Dom Pedro were greatly impressed and their outspoken enthusiasm went a long way toward attracting favorable attention to offset the universal scepticism of the public.

It was not until August, 1877, when there were 778 telephones in use, that the "Bell Telephone Association" was formed, Bell, Watson, Bell's father-in-law Gardener G. Hubbard, and Thomas Sanders, in whose cellar the invention was first started, were the members of the Company. Sanders was the sole financial backer. Bell was no business man, and after 1877 he had little active connection with the organization of the telephone industry. He married in that year one of his former pupils, went abroad to help introduce the telephone in England, returned, and with characteristic energy turned to experiments with flying machines.

Bell's inventions other than the telephone include the photophone, the induction balance, a telephone probe for the detection of bullets in the human body (for which he received an honorary M.D. from Heidelberg University at its 500th anniversary) and, with C. A. Bell and Sumner Taintor, the graphophone. It was his practice to keep complete records of his scientific researches, and the several hundred volumes containing these records cover a multiplicity of subjects from the utilization of waste heat to notes on eugenics and the biological history of a cat.

Dr. Bell had received many honors. In 1880 the French Government gave him the Volta Prix, and the engineering profession acknowledged his genius by bestowing the John Fritz Medal in 1907. He had received gold medals from The London Society of Fine Arts, the Royal Albert, the Elliott Cresson, and the Hughes Medal of the Royal Society of Arts. He was an officer of the French Legion of Honor. He founded and endowed with $250,000 the American Society to Promote Teaching of Speech to the Deaf. He was at one time President of the National Geographical Society, and was a member of the National Academy of Sciences, the American Philosophical Society, the American Academy of Arts and Sciences, and the American Association for the Advancement of Science.

The Treasure House of Aeroplane Design

McCook Field to Establish Museum of Aeroplanes and Aircraft Engines

ONE of the greatest difficulties encountered by designers of aircraft engines and aeroplanes lies in the inability to secure concise information about the various details of design. For example, the usual printed descriptions of an aeroplane engine tell about the number of cylinders, their dimensions and such main features, but when it comes to the exact location of the valves and the design of the cams, they are usually silent or indefinite. Even an inspection of the engine does not help in many cases as the desired part may be concealed from view and can be carefully studied only after the engine is dismantled. This cannot always be done for the sole benefit of the prospective designer.

The authorities of the Air Service, War Department, at McCook Field, took steps to remedy this situation for the benefit of their own engineering department as well as for legitimate use by other American engineers and manufacturers. During the war, through various agencies of the government, quite a collection of aeroplane engines of American, Allied and enemy origin was assembled at McCook Field, and this collection is to form the nucleus of the Museum of Aircraft Engine and Aeroplane Design now being installed in several hangars on the field.

The great value of this collection at McCook Field lies in the method of display adopted in place of the impressive but not always enlightening method of erecting engines on stands. Two engines have been secured for every type and one engine is placed on the stand completely assembled which gives a clear idea of its general construction and assembly. The other engine is entirely disassembled, the various parts being placed either in glass cabinets where they can be easily inspected and if necessary reached, or on shelves under the glass cabinets, these shelves containing mainly duplicate and very large parts. The designer, therefore, can easily inspect and measure any part of any of the engines shown in the Museum. There is no doubt that a few days spent in the Museum would give more information as to current practice in aircraft-engine and aeroplane design than could be obtained by any other means except extensive trips through the whole of Europe and the United States and visits to the factories. In a pocket by the side of each cabinet are placed printed descriptions, tracings, diagrams and such information as is available about each engine or plane. In addition any visitor who can show legitimate interest in this subject will be granted access to the bibliographical index files of the Engineering Division, McCook Field, in itself a veritable mine of information, often to be found nowhere else.

Fig. 1 A Disassembled Engine is Placed in the Cabinet

As it is impossible to apply the same method to aeroplanes on account of lack of space, somewhat simplified arrangements will show such details as construction of wings, landing gear, etc.

One of the most gratifying features of the McCook Field Museum is that there is no intention of making it a departmental preserve.

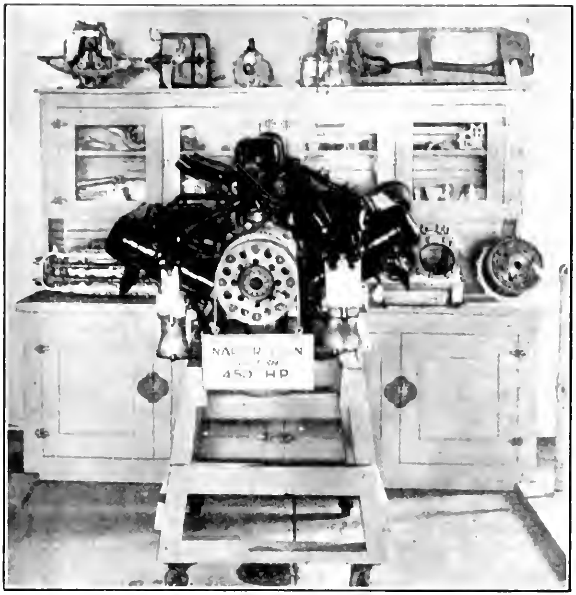


Fig. 2 The Engine and Cabinet are Available to American Designers

On the contrary, every facility of the Museum will be thrown open to any American engineer or manufacturer who can show a legitimate interest in this subject. Work is now proceeding on the construction of the cabinets and stands, and it is expected that the Museum will be opened the latter part of September.

Carbon Tetrachloride for Electric Fires

Engineers who look to the carbon tetrachloride fire extinguisher as the reliable aid in case of electric-arc fires will be interested in the recent report of the Bureau of Mines which acquitted the carbon tetrachloride extinguisher of the charge that the gases originated in the extinguisher caused the asphyxiation of a number of passengers in a New York City subway fire on July 6. A short circuit caused the fire in an express train on the Lexington Avenue Subway. The passengers were removed without casualty although it was necessary to take a number to hospitals so that they could be revived from the effects of fumes caused by the fire. At first it was thought that the carbon tetrachloride with which all subway trains are equipped caused the asphyxiation. The Report of the Transit Commission, which was assisted by the experts from the Federal Bureau of Mines, stated that the symptoms of the patients as shown in the hospital records can all be accounted for by the known effects of gases resulting from the burning of insulating materials such as rubber, varnish and paint, and that the symptoms given are not characteristic of phosgene or carbon tetrachloride poison. Furthermore, the Report states that carbon tetrachloride is a standard fire extinguisher in general use, approved by the National Board of Fire Underwriters and is particularly adapted for fires produced by short circuits in electrical equipment and apparatus because it is a non-conductor of electric current.

Engineering and Industrial Standardization

Fire-Hose Couplings

A NUMBER of conferences which have been held during the past two months have added new impetus to the campaign for an American Standard Fire-Hose Coupling. As far back as 1873 the importance of a universally adopted fire-hose coupling in the elimination of fire waste was recognized by those most directly connected with fire fighting.

At conventions of fire chiefs and the International Association of Fire Engineers this subject, received much attention, and finally a set of standard dimensions for the $2^{1}/_{2}$-, 3-, $3^{1}/_{2}$- and $4^{1}/_{2}$-in. couplings were agreed upon. In these early discussions the National Fire Protection Association, the New England Water Works Association, the American Water Works Association, and the National Board of Fire Underwriters took an active part. Later The American Society of Mechanical Engineers and the Bureau of Standards reviewed the work of the earlier committees and approved what was then generally known as the National Standard. The A.S.M.E. Committee's report was published in 1913 and the Bureau of Standard's Bulletin No. 50 appeared in 1914. Since that time a painstaking and consistent effort has been made by the National Board of Fire Underwriters to encourage the adoption of this standard coupling by the cities and towns of the United States. For those which had previously adopted a coupling whose pitch and outside diameter were slightly different from the standard this Board arranged for the development of a set of standardizing tools by a well-known firm of tap and die makers.

The Progress Report of the National Screw Thread Commission placed a stamp of approval on this fire-hose standard and completed it by the addition of a set of manufacturing tolerances. It was the discussion of these tolerances which was the immediate reason for the recent conferences. An agreement has been reached between the representatives of the National Board of Fire Underwriters, the National Screw Thread Commission, and The American Society of Mechanical Engineers. So it will probably not be long before the manufacture of standard fire-hose couplings will be placed on an interchangeable-production basis by the use of steel working gages which can be certified to by the Bureau of Standards.

It is proposed to present this standard in the near future to the American Engineering Standards Committee for approval as an American Standard.

Four New American Standards

Recent actions by the American Engineering Standards Committee have resulted in the following Standards:

SAFETY CODE FOR FOUNDRIES

This Code is a revision of that developed by the American Foundrymen's Association and the National Founders Association, joint sponsors of the new code. The revision was worked out by a thoroughly representative Sectional Committee organized under the Rules of the American Engineering Standards Committee and included four representatives of makers and owners of foundry equipment, four of governmental bodies, two of technical associations, two of insurance organizations, and a representative of foundry employees.

This new *tentative* American Standard Code No. 20 deals with foundry conditions only, omitting such subjects as building construction, exits, stairways, elevators, lighting, sanitation, etc., as these subjects are covered by other Safety Codes which have an official status before the American Engineering Standards Committee. The code consists of 124 sections which are grouped under the following twelve main divisions: entrances, floors, pits, and galleries, gangways, aisles, foundry equipment, finishing and cleaning, heating, ventilation, operating rules, protection devices, employment of females, and recommendations.

The Sectional Committee which revised the foundry safety code and recommended it for approval by the A.E.S.C. included representatives of the National Founders Association, the Association of Government Labor Officials, the U. S. Department of Labor, the American Foundrymen's Association, the National Association of Mutual Casualty Companies, the National Safety Council, the U. S. Bureau of Standards, the National Association of Manufacturers, the National Bureau of Casualty and Surety Underwriters, the American Society of Safety Engineers, and the U. S. Public Health Service.

NATIONAL ELECTRICAL SAFETY CODE

The National Electrical Safety Code of the Bureau of Standards which covers the generation, distribution and utilization of electricity for power, light and communication has been approved as American Standard No. 21.

In making public this decision, the Standards Committee announces that there is now in process of formation a thoroughly representative Sectional Committee to consider any revisions of Part 2 of this Code, Rules for the Installation and Maintenance of Overhead and Underground Electrical Supply and Signal Lines, which may be deemed necessary by any of the interested parties. There are also being organized three sub-committees to take up the unification of crossing specifications under the three following heads: Signal Lines Crossing Railways; Power Lines Crossing Railways; and Power Lines Crossing Signal Lines.

It is believed that this action, together with the organization of the representative committees to take care of the revision of the Code and to prepare the crossing specifications, constitutes one of the most important steps yet taken in securing national uniformity in these matters.

ILLUMINATING ENGINEERING NOMENCLATURE AND PHOTOMETRIC STANDARDS

This group of Standards as published by the Illuminating Engineering Society in 1918 has been approved as American Standard No. 22 with the substitution of six internationally agreed upon definitions for certain ones of the 1918 rules. The definitions which have been reworded are: luminous flux, luminous intensity, illumination, candle, lumen, and lux.

The special committee of the American Engineering Standards Committee which examined the proposal submitted by the I.E.S. and which recommended approval of the nomenclature and photometric standards included representatives of the U. S. Bureau of Standards, the American Gas Association, the American Physical Society, the International Acetylene Association, the Optical Society of America, the American Institute of Electrical Engineers, the Illuminating Engineering Society, and the National Electric Light Association.

SPECIFICATIONS FOR TESTING AND USE OF PERMISSIBLE EXPLOSIVES APPROVED

The specifications for the testing and use of permissible explosives submitted to the American Engineering Standards Committee by the U. S. Bureau of Mines has been approved by the A.E.S.C. as an American Standard. It therefore becomes American Standard No. 23.

The Special Committee of the A.E.S.C. which examined the proposed specifications and recommended them for approval by the Standards Committee included representatives of the U. S. Department of Interior, the American Mining Congress, the Coal Mining Institute of America, the Mine Inspectors' Institute of America, the American Society of Civil Engineers, the Institute of Makers of Explosives, and the U. S. Department of Agriculture.

Your Comment is Requested

Stacks. Some of our readers have proposed the standardization of the specifications on which the estimates for circular brick stacks are based. A few of the items which might be specified are: maximum wind pressure, maximum permissible stress in brickwork, amount of lining, etc. Should steel stacks also be considered?

Valves, Cocks and Faucets. During the past two months the American Engineering Standards Committee has carried on a considerable amount of correspondence with a view to determining

whether or not these products offer a field for standardization and, if so, what dimensions should be considered. The Committee needs all the guidance it can have.

Shop Drawing Sizes. Periodically the A.S.M.E. Standards Department receives an inquiry concerning the supposed A.S.M.E. standard sizes for shop drawings. There are no such standards but many firms have given considerable attention to the problem. Should this information be collected and studied by a properly organized committee for the purpose of developing a set of generally acceptable standard sizes?

BOOK NOTES

Beleuchtung der Bahnhöfe und der Bahnhofshochbauten. By Richard Sarre. Wilhelm Engelmann, Leipzig, 1922. (Handbuch der Ingenieurwissenschaften, 5. Teil, 5. Band.) Cloth, 7×10 in., 300 pp., illus. 151 M.

The primary object is to provide a discussion upon the principles and systems of lighting railway stations and railway office buildings. But since every existing method of lighting has been used for these purposes and since the principles of artificial lighting are of general application, the book is in reality a concise survey of methods of illumination and of the laws governing their use.

Les Colloides. Par J. Duclaux. Gauthier-Villars et Cie, Paris, 1922. (Actualités scientifiques.) Paper, 5×7 in., 305 pp. 10 fr.

This work does not purport to be encyclopedic. It is, rather, a concise statement of chosen facts woven into a coherent account, from a single point of view, with useless details and superimposed theories avoided. Certain modifications have been made in the new edition. The author is Director of the Laboratory of the Pasteur Institute.

Mathematical Theory of Probabilities. By Arne Fisher. Second edition, enlarged. The Macmillan Co., New York, 1922. Cloth, 6×9 in., 289 pp. $5.

The author's aim has been to treat all the modern researches upon this important branch of applied mathematics from a common point of view, based upon the mathematical principles laid down by Laplace, and to present a theory of probabilities as developed in recent years of value to the practical statistician, the actuary, the engineer and the biologist, as well as students of mathematics. The second edition is extended to nearly twice its original size by added chapters on frequency functions and their applications. Mr. M. C. Rorty contributes an introductory note indicating some of the practical applications of the theory of probabilities to business problems.

Les Progrès de la Métallurgie du Cuivre. Par Auguste Conduché. Masson et Cie; Gauthier Villars et Cie, Paris, 1922. (Encyclopédie Léauté.) Paper, 5×8 in., 254 pp., illus., 14 fr.

Considerable progress has been made in recent years in the metallurgy of copper, due in part to the technical improvement of machinery and plants, but still more to scientific investigation and to the careful utilization of the chemical reactions that occur. This book is a concise account of this progress. It provides a statement of present knowledge of the properties of copper, the effects of impurities, its alloys, and the methods of smelting and refining, with careful attention to scientific principles and to the economic factors. It also presents a typical example of the value of systematic research and scientific methods for the development of an industry.

On The Electro-Deposition of Iron. By W. E. Hughes. H. M. Stationery Office, London, 1922. (Dept. of Scientific and Industrial Research. Bulletin No. 6.) Paper, 50 pp., plates, 6s. 8½d.

Reports the results of an extensive laboratory investigation of the structure of electrodeposited iron, together with the author's conclusions regarding the influence of various factors upon this structure. The effects of temperature, current density, and movement of the cathode or electrolyte are given special attention. The conclusion is reached that the general theories entertained in regard to the crystallization of other substances hold also for deposited metal and that the dominant factor governing structure is concentration.

Pulling Together. By John T. Broderick. Robson & Adee, Schenectady, 1922. Cloth, 5×8 in., 144 pp., $1.

A discussion of current problems connected with the relations of capital and labor, with employee representation as the central theme. Dr. Steinmetz has contributed a brief introduction.

SYNTHETIC-GASOLINE PRODUCTION

(*Continued from page 595*)

B. = gravity of crude oil in degrees Baumé
n = percentage of natural gasoline of 58 deg. B. gravity in the crude
c = value of crude oil at refinery in dollars per bbl.
f = value of fuel oil at refinery in dollars per bbl.
s = value of gas oil at refinery in dollars per bbl.
a = percentage of artificial or synthetic gasoline in crude.

(1) Percentage of artificial gasoline obtainable by commercial cracking:

$$a = \frac{[100 - n]\,[35 + 1.45\,(B. - 10 - 0.3n)]}{100}$$

Total gasoline = $n + a$

(2) Cost (C_1) of gasoline per gallon when made by skimming only:

$$C_1 = \frac{c + 0.35 - f\,(0.95 - 0.01\,n)}{0.42\,n}$$

(3) Cost (C_2) of gasoline per gallon when made by cracking and skimming:

$$C_2 = \frac{c + 0.40 + a\,(0.0202 + 0.015\,f) - f\,(0.95 - 0.01\,n)}{0.42\,(a + n)}$$

(4) Cost (C_3) of gasoline per gallon when made by cracking gas oil:

$$C_3 = \frac{\$2.02 + 1.41\,s - 0.05\,f}{42}$$

Illustrations of Preceding Formulas

(1) Total gasoline from crude oils:

	Sp. Gr., deg. B.	Per Cent Natural	Per Cent Artificial	Per Cent Total
Mexia, Texas crude	37	5	68	73
Burkburnett, Texas	40	40	37	77
Ranger, Texas	38	25	49	74
Panuco, Mexico	12	5	34	39
Tuxpan, Mexico	17.5	15	32	47

(2) Cost (C_1) of gasoline by skimming only (c = $2.00 per bbl.; n = 25 per cent; B. = 37 deg.; f = $1.00 per bbl.):

$$C_1 = \frac{2.35 - 1\,(0.95 - 0.25)}{(0.42)\,(25)} = 15.7 \text{ cents per gal.}$$

(3) Cost (C_2) of gasoline by skimming and cracking, using values given in (2):

$$C_2 = \frac{2.00 + 0.40 + 47.4\,(0.0202 + 0.015) - (0.95 - 0.25)}{0.42\,(47.4 + 25.0)} = 11 \text{ cents per gal.}$$

(4) Cost (C_3) of gasoline made from gas oil with s = $1.25 and f = $1.00:

$$C_3 = \frac{\$2.02 + 1.75 - 0.05}{42} = 8.9 \text{ cents per gal.}$$

ACID-RESISTING METALS AND ALLOYS

(*Continued from page 580*)

of acid or combinations of acids other than sulphuric, namely, nitric, hydrochloric, hydrofluoric, acetic, stearic, oleic, etc., and outside of those with nitric acid, have been fairly successful. Most of the tests have been conducted with acids and solutions at normal temperature. When subjected to the higher temperatures the losses are much greater, and this makes the solution of the problem even more complex.

There are few known metals or alloys that will resist the action of nitric acid or a combination of nitric with other acids, and the general use of these few is either prohibited by their rareness and cost, or by the fact that they cannot be produced in such a way as to make them at all interesting from a commercial standpoint so far as mine pumps and accessories, apparatus for the chemical industries, etc., are concerned.

Metals and alloys which are required to be highly resistant to the effects of corrosion and erosion, and at the same time commercially practicable, must be of such a nature that they can be easily cast, rolled, drawn, and machined, so that all parts of a pump or other apparatus can be readily made from them, including piping, valves, etc., otherwise the field covered by such metals must be more or less confined and limited.

THE ENGINEERING INDEX

(Registered United States, Great Britain and Canada.)

THE ENGINEERING INDEX presents each month, in conveniently classified form, items descriptive of the articles appearing in the current issues of the world's engineering and scientific press of particular interest to mechanical engineers. At the end of the year the monthly installments are combined along with items dealing with civil, electrical, mining and other branches of engineering, and published in book form, this annual volume having regularly appeared since 1906. In the preparation of the Index by the engineering staff of The American Society of Mechanical Engineers some 1200 technical publications received by the Engineering Societies Library (New York) are regularly reviewed, thus bringing the great resources of that library to the entire engineering profession.

Photoprint copies (white printing on a black background) of any of the articles listed in the Index may be obtained at a price of 25 cents a page. When ordering photoprints identify the article by quoting from the Index item: (1) Title of article; (2) Name of periodical in which it appeared; (3) Volume, number, and date of publication of periodical; (4) Page numbers. A remittance of 25 cents a page should accompany the order. Orders should be sent to the Engineering Societies Library, 29 West 39th Street, New York.

ACCOUNTING

Construction Projects. Accounting for Construction Projects, W. Paxton Little. Elec. World, vol. 79, no. 24, June 17, 1922, pp. 1211–1215, 18 figs. Commission regulation requirements give importance to proper accounting; actual unit-cost information needed as guide to engineers and executives; outline of specific methods that have been found successful.

AERONAUTICAL INSTRUMENTS

Air Service Tests. Air Service Tests New Instruments, S. R. Winters. Aviation, vol. 12, no. 26, June 26, 1922, pp. 755–756, 3 figs. Rate of climb indicator, bubble statoscopes and new barograph tested in balloon flights.

Sylphon Diaphragms. Sylphon Diaphragms, H. N. Eaton and G. H. Keulegan. Aerial Age, vol. 15, no. 15, June 26, 1922, pp. 370–372, 4 figs. Method for predicting their performance for purposes of instrument design.

AERONAUTICS

Government Laboratories, Aid. Government Laboratories Aid Aircraft Growth, P. M. Heldt. Automotive Industries, vol. 46, no. 26, June 29, 1922, pp. 1423–1426, 3 figs. Aeronautic session of S. A. E. develops discussion on aircraft performance formulas, government subsidies, and commercial flying. McCook field work is shown in motion pictures.

Standard Atmosphere. Standard Atmosphere, Willis Ray Gregg. Nat. Advisory Committee for Aeronautics Report no. 147, June 1922, 4 figs. Use of Toussaint's formula in determining standard atmosphere up to 33,000 ft. and tables showing values. Based in part on paper entitled An Aerological Survey of the U. S. to be published by Weather Bureau.

AIR COMPRESSORS

Centrifugal. A New Air Compressor (Ein Neuer Luftkompressor), E. Löwenstein. Deutsche Optische Wochenschrift, vol. 8, no. 22, May 28, 1922, pp. 413–414, 4 figs. Describes new compressor by Götz, having very high efficiency and requiring little power, for use in glass-blowing and technical glass industries.

AIRCRAFT

Research in America. America Makes Creditable Showing in Aircraft Research, Archibald Black. Automotive Industries, vol. 46, no. 23, June 8, 1922, pp. 1257–1265, 13 figs. Speed and reliability increased; helicopters; variable-pitch propeller; landing-field development; Handley Page slotted wing.

AIRPLANE ENGINES

Developing, Method of. A Method of Developing Aircraft Engines, Geo. E. A. Hallett. Soc. Automotive Engrs. Jl., vol. 10, no. 6, June 1922, pp. 457–462, 10 figs. Outline of procedure taken by Air Service before beginning actual design, and subsequent developments.

German, Siemens-Halske. A New German Aeronautical Engine, Erik Hildesheim. Aviation, vol. 12, no. 24, June 12, 1922, p. 693, 3 figs. Siemens-Halske 50–60 hp. air-cooled radial engine; first example of German post-war commercial design.

German 5-Cylinder Radial. A New Low-Power German Radial Air-Cooled Aero Engine. Flight, vol. 14, no. 23, June 8, 1922, pp. 326–327, 3 figs. Description of 60-hp. Siemens-Halske 5-cylinder, 4-stroke engine.

Metals for. Metallurgical Problems of the Airplane Engine (Le Probleme metallurgique pose par le Moteur d'Aviation), C. Grard. Aeronautique, vol. 4, no. 46, May 1922, pp. 156–165. Conditions metals must fulfill for construction of airplane engines.

Silencers. The Silent Airplane and the Silent Engine (L'avion silencieux et la moteur silencieux), Charles Dollfus. Aéronautique, vol. 4, no. 36, May 1922, pp. 145–147, 3 figs. Describes Schneebeli and Birger apparatus for reducing noise.

AIRPLANES

Aerofoils. Flow Tests on Slotted Aerofoils. Flight, vol. 14, no. 22, June 1, 1922, pp. 315–316, 15 figs. Some experiments on behavior of eddies at various points, angles and velocities as shown by means of sal-ammoniac smoke.

BaCo Skylark. The BaCo Skylark. Flight, vol. 14, no. 24, June 15, 1922, pp. 337–339, 5 figs. Description of two-seater tractor biplane fitted with 60-hp. Lawrence air-cooled engine. Constructed by Bethlehem Aircraft Corp.

Propulsion Efficiency vs. Performance. Propulsion Efficiency vs. Performance, Roy G. Miller and F. E. Seiler, Jr. Aviation, vol. 12, no. 25, June 19, 1922, pp. 716–719, 5 figs. Influence of propulsion efficiency on performance of airplanes demonstrated by some well known examples.

Performance Formulas. Airplane Performance Formulas, Edward P. Warner. Soc. Automotive Engrs. Jl., vol. 10, no. 6, June 1922, pp. 469–474, 7 figs. Process of deriving simplified formulas and consideration of elements such as minimum and maximum speeds, climbing ability, etc.

Slotted-Wing Theory. Theory of the Slotted Wing, A Betz. Nat. Advisory Committee for Aeronautics Technica Notes, no. 100, June 1922, 13 pp., 7 figs. Means of varying coefficient of lift, thereby reducing difficulties of taking off and landing and making greater flight speeds possible; suggestions for theories from which formulas may be developed. From Berichte u. Abhandlungen der Wissenschaftlichen Gesellschaft fur Luftfahrt, no. 6, Jan., 1922. See also Aerial Age, vol. 15, no. 15, June 26, 1922, pp. 366–368, 6 figs.

Two-Way. Introducing the Two-Way Airplane, John B. Flowers. Aviation, vol. 13, no. 1, July 3, 1922, pp. 9–10, 1 fig. Tentative design presented to stimulate thought in this direction and criticism of idea, by well-known aeronautical engineer.

AIRSHIPS

Wright Dirigible Engine. The Wright Dirigible Engine and Its Development for the Navy, George J. Mead. Aerial Age, vol. 15, no. 15, June 19, 1922, pp. 342–343. Six-cylinder, vertical, water-cooled engine with 1850 cu. in. displacement, weighing 1320 lb. and developing 400 hp.

ALLOYS

See ALUMINUM ALLOYS, NICKEL ALLOYS, ZINC ALLOYS.

ALUMINUM

Coating With. Coating With Aluminum (Les recouvrements par l'aluminium), Léon Guillet. Révue de Métallurgie, vol. 19, no. 5, May 1922, pp. 296–297. Describes various processes and their successful application.

ALUMINUM ALLOYS

Aluminum-Silicon. Aluminum-Silicon Alloys and Their Industrial Uses (Les alliages aluminium-silicum et leurs emplois industriels), Leon Guillet. Révue de Métallurgie, vol. 19, no. 5, May 1922, pp. 303–310, 15 figs. Reviews development of this type of alloy and discusses new types and their properties.

Aluminum-Zinc. A Study of Alloys of Aluminum and Zinc, D. Hanson and Marie L. V. Gayler. Raw Material, vol. 5, no. 5, June 1922, pp. 174–181, 29 figs. Results of experiments on work along this line; effects of age hardening. Paper read before British Inst. of Metals.

Light. Light Aluminum Alloys, Prof. F. C. Lea. Metal Industry (Lond.), vol. 20, no. 23, June 9, 1922, pp. 533–536, (includes discussions), 2 figs. Effect of various combinations on melting point and characteristics of alloys. From paper read before Inst. of Metals.

Melting and Pouring. Melting and Pouring Aluminum Alloys. Am. Mach., vol. 57, no. 1, July 6, 1922, pp. 1–4. Proper care of furnace; effect of melting and pouring temperatures on castings; how to overcome foundry difficulties.

[See also DURALUMIN.]

AMMONIA

Capacity Table. A Pound of Ammonia, John E. Starr. Refrig. World, vol. 57, no. 6, June 1922, pp. 19–20. Table showing work of a pound of ammonia when heat is received at various temperatures and discharged at various other temperautres.

Chart, Bureau of Standards. The New Bureau of Standards Ammonia Chart. Ice & Refrigeration, vol. 62, no. 6, June 1922, pp. 461–464, 2 figs. Historical facts; nature of chart, properties of anhydrous ammonia which are represented; characteristic curves to show properties; phases of cycles of operation; some common cycles of operation shown graphically.

ASHES

Use for Refiring. Ash Treatment (Ashen-Aufbereitung), F. A. Gruessner. Technische Blätter, vol. 12, nos. 8 and 9, Feb. 25 and Mar. 4, 1922, pp. 81–82 and 89–90, 3 figs. Feb. 25: Discusses processes of preparing ashes for refiring, such as magnetic separation. Mar. 4: Detailed discussion of magnetic separation.

Washing for Refiring. Utilization of Ashes (Aufbereitung von Feuerungsrückständen), G. Reder. Archiv für Wärmewirtschaft, vol. 3, no. 5, May 1922, pp. 83–87, 15 figs. Describes number of plants for washing ashes for reuse under boilers.

AUTOMOBILE ENGINES

Air-Cooled. Air-Cooled Engines Subject of Widespread Current Research, J. Edward Schipper. Automotive Industries, vol. 46, no. 23, June 8, 1922, pp. 1214–1218, 7 figs. Producing cooling at hottest points on combustion chamber wall. General Motors copper-cooled car near production.

Citroen, Fuel Economy. Citroen Which Lowered World's Fuel Consumption Record, W. F. Bradley. Automotive Industries, vol. 46, no. 26, June 29, 1922, pp. 1434–1435, 2 figs. New detachable head engine used in fuel trials; total valve head diameter $1\frac{1}{8}$ in.; reciprocating parts lightened; compression from 65–68 lb.; lubrication follows standard lines; 1-section connecting rods; rocker arms mounted on two separate shafts.

Diesel Type. Small Diesel Type Automotive Engine Now in Production. Automotive Industries, vol. 46, no. 24, June 15, 1922, pp. 1320–1321, 2 figs. Four-cylinder Austrian engine designed to avoid excessive compression and combustion pressures, thus

reducing strain on working parts. Hindl engine can be started by means of hand crank and operates at speed of 1150 r. p. m.

Economy and Flexibility Aims. Better Economy and Flexibility Are Chief Aims of Engine Development, Herbert Chase. Automotive Industries, vol. 46, no. 23, June 8, 1922, pp. 1266–1269, 4 figs. Research and development work tending towards 40 miles per gal., lower speed and higher torque, nonthrottling engines.

Lubrication. Oil-Pumping, Geo. A. Round. Soc. Automotive Engrs. Jl., vol. 10, no. 6, June 1922, pp. 309–312, 4 figs. Factors controlling rate of oil consumption, methods of lubrication, including splash and force-feed systems, oil-pumping troubles.

Oil Consumption. Oil Consumption, A. A. Bull. Soc. Automotive Engrs. Jl., vol. 10, no. 6, June 1922, pp. 313–322, 19 figs. Fundamental factors affecting oil consumption. Methods of testing.

Overhead Camshaft. Overhead Camshaft Passenger-Car Engines, P. M. Heldt. Soc. Automotive Engrs., vol. 10, no. 6, June 1922, pp. 489–498, 19 figs. Adoption of overhead valves in automobile engines, their use on American cars greatly increased.

Pistons, Light-Metal. Light-Metal Pistons for Automobile Engines. Engineering, vol. 113, no. 2945, June 9, 1922, pp. 716–718, 3 figs. Competitive tests under auspices of German Transport Ministry and Verein Deutscher Motorfahrzeug-Industrieller by Prof. Gabriel Beckee.

AUTOMOBILE FUELS

Alcohol. Alcohol Motor Fuel Research. Petroleum Times, vol. 7, no. 176, May 20, 1922, pp. 711–712. Report of four series of tests which showed that all speeds, both with high and low compression, thermal efficiency obtained with alcohol was higher than that obtainable with petrol or benzol at any compression which could be employed with them.

Detonation of, Blended. Detonation Characteristics of Some Blended Motor-Fuels, Thomas Midgley, Jr. and T. A. Boyd. Soc. Automotive Engrs. Jl., vol. 10, no. 6, June 1922, pp. 451–456, 5 figs. Effects of admixtures of various percentages of alcohol and alcohol-benzine for reducing detonating tendency of paraffin hydrocarbons.

Low-Volatile. Can Less Volatile Motor Fuels Be Used Successfully? F. C. Mock and M. E. Chandler. Automotive Industries, vol. 46, no. 25, June 22, 1922, pp. 1372–1376, 8 figs. Proper fuel preparation prior to combustion involves formation of continuously homogeneous mixture without liquid film or drops at lowest possible temperature. Advantages and disadvantages of present methods of heat application. Condensed from paper read before Soc. Automotive Engrs.

Research, Effect on Industry. Automotive Engineering Development Rests Largely on Fuel Research, Herbert Chase. Automotive Industries, vol. 46, no. 23, June 8, 1922, pp. 1219–1231, 16 figs. Gasoline substitutes used in other countries; cracking processes developed; work of Ricardo and Kettering.

AUTOMOBILE INDUSTRY

André Citroen Plant, France. The André Citroen Establishments. Engineering, vol. 113, no. 2945 June 9, 1922, pp. 705–708, 5 figs. Description of plant where sixty 10-hp. automobiles are turned out daily. Some details of buildings which cover 20 acres.

British Research, Economy. British Automotive Research Devoted to Securing Operating Economy, M. W. Bourdon. Automotive Industries, vol. 46, no. 24, June 15, 1922, pp. 1322–1324. Use of combined oil and air cooling for engines being studied in several quarters. Experiments proceeding to further use of light alloys in chassis construction. Reducing bus operating costs.

Canadian Plant at Ford, Ont. Producing 55,000 Cars and Trucks a Year. Can. Machy., vol. 27, no. 25, June 22, 1922, pp. 26–31, 11 figs. Outstanding features of Ford Motor Co. of Canada at Ford, Ontario.

General Motors Plant, Chicago. Making Five Types of Cars At One Plant. Can. Machy., vol. 27, no. 25, June 22, 1922, pp. 35–37, 6 figs. Outstanding features of plant where two types of Chevrolet, McLaughlin-Buick, Oldsmobile and Oakland are turned out for Canadian consumption.

Research in Iron and Steel. Better Cars and Trucks May Result from Iron and Steel Research, P. M. Heldt. Automotive Industries, vol. 46, no. 23, June 8, 1922, p. 1270. Study of chrome-molybdenum steel, high-carbon steel brake drums, resistance-to-wear investigation and heat treatment.

Research in Light Metals. Light Metal Research Will Affect Future Car and Truck Design. Automotive Industries, vol. 46, no. 23, June 8, 1922, pp. 1278–1279. New all-aluminum car. Rosenhain's aluminum alloy for pistons. Germans light alloys in high-speed engines. Aluminum forging and soldering.

Research in Non-Ferrous Metals. Non-Ferrous Metal Research Affects Design of Small Automotive Parts. Automotive Industries, vol. 46, no. 23, June 8, 1922, pp. 1259–1260. New coefficient of expansion determined for nickel; properties of monel metal; bearing flux.

S.A.E. Standard Report. New S.A.E. Standard Report of Interest to Many Manufacturers. Automotive Industries, vol. 46, no. 24, June 15, 1922, pp. 1329–1336, 10 figs. Recommendations covering bumper mountings, oil-drain plugs, spring steel, truck-axle parts, electrical equipment, tractor drawbar adjustment, bronze and aluminum sheet, bearing metals, ball studs, screw threads and serrated fittings are important to vehicle as well as to parts makers.

AUTOMOBILES

Differentials, With and Without. With and Without the Differential, G. E. Bradshaw. Autocar, vol. 48, no. 1382, April 15, 1922, pp. 611–613. Upholding argument that differentialless axle is not suitable for touring cars.

Suspension. New System of Spring Suspension for Automotive Vehicles, H. M. Crane. Soc. Automotive Engrs. Jl., vol. 10, no. 6, June 1922, pp. 463–465, 2 figs. History; Hotchkiss drive for shaft driven cars, rear-axle mountings and device developed by author.

Taxicabs, European. New European Taxicabs Are Designed for High Economy, W. F. Bradley. Automotive Industries, vol. 46, no. 24, June 15, 1922, pp. 1316–1319, 3 figs. Citroen with small four cylinder engine, 111-in. wheelbase and 46-in. track, and body seating only two passengers has proved highly successful. 3200 Renault cabs with larger engine, same wheelbase, 56-in. track, and four-passenger body are now competing.

Transmission, Mechanical Shift. Gear Transmission with a Mechanical Shift, H. O. Herzog. Am. Mach., vol. 57, no. 1, July 6, 1922, p. 17, 5 figs. on p. 16. Describes Saden gear shift, a German device; 4 speeds and reverse; operator merely selects speed desired, shift is mechanical.

Trojan Two-Stroke. The 10 Hp. Two-Stroke Trojan. Autocar, vol. 48, no. 1392, June 24, 1922, pp. 1071–1073, 9 figs. Small utility car incorporating novel two-stroke engine, epicyclic gear, and solid tires.

Waverley. The New 10–15 Hp. Waverley Car. Auto, vol. 27, no. 23, June 8, 1922, pp. 467–470, 12 figs. New and lighter model of well known London-made car with Coventry-Simplex, four-cylinder monobloc engine.

Webb Light Car. The Webb Light Car. Auto, vol. 27, no. 24, June 15, 1922, pp. 489–491, 11 figs. Description of British car of pleasing design, four-cylinder Alpha engine of 1,088 cc. piston displacement.

AVIATION

Traffic Law Proposed. Proposed Air Traffic Law, Geo. Ripert. Aerial Age, vol. 15, no. 14, June 12, 1922, pp. 320–323. Suggestions for international laws deduced from those adopted at international conventions and by various governments.

B

BEAMS

Plate. Dimensions of Plate Beams (Dimensionierung Einfach Bewehrter Plattenbalken), Leo Báron. Bauingenieur, vol. 3, no. 9, May 15, 1922, pp. 273–275. Gives new, simplified, expeditious and reliable method of calculation, and explains it by practical examples.

BEARING METALS

Babbitt. The Microstructure of Babbitt Metal, A. McArthur Johnston and R. W. Irwin. So. African Instn. of Engrs. Jl., vol. 20, no. 10, May 1922, pp. 197–211, 21 figs. Characteristics, construction, and properties of alloys recommended by Chamber of Mines Eng. Standardization Committee; nature of microstructure o feach alloy and physical properties likely to be found.

White-Metal and Red-Brass. White Metal and Red Brass Bearing Metals for Machines, Bushings, Collars, Etc. (Weissguss- und Rotguss-Lagermetalle für Maschinen, Lagerfutter, Zapfenlager usw). Zeit. für die Gesamte Giessereipraxis, vol. 43, no. 23, June 10, 1922, pp. 316–317. Composition of bearing metals, especially for machine tools; gives tables of percentages of tin, zinc, antimony, copper, lead, etc., also of their mechanical properties, elasticity, tensile strength, elongation, hardness, construction.

BEARINGS

Babbitted, Troubles. Fourteen Causes of Trouble With Babbitted Bearings, L. D. Allen. Belting, vol. 20, no. 6, June 1922, pp. 55–56, 1 fig. Points that should be investigated when bearings give trouble.

Motor. Some Pointers on Bearings, A. L. Gear. Elec. Rev. & Indus. Engr., vol. 80, no. 6, June 1922, pp. 265–270, 309–310, 13 figs. Sleeve-bearing materials, design and construction.

Steam-Engine, Lubrication of. The Problem of Lubricating Steam-Engine Bearings, W. F. Osborne. Power, vol. 56, no. 2, July 11, 1922, pp. 53–54, 1 fig. Method of lubrication; effect of characteristics of engine on selection of suitable lubrication.

BEARINGS, BALL

Advantages. On the Quality of Various Bearings and the Advantages of Ball Bearings (Note sur les qualités générales des divers paliers de transmissions, avantages des paliers à billes), H. Bursic. Révue Générale de l'Électricité, vol. 11, no. 21, May 27, 1922, pp. 792–794, 3 figs. Progress made in recent years in journal bearings and SKF ball bearings.

BELT DRIVE

Power Transmission by. Power Transmission by Belting. Machy. (Lond), vol. 20, no. 507, June 15, 1922, pp. 325–327, 4 figs. Characteristics of leather belting and charts for simplifying calculations.

Power Transmitted. How Much Power is Belt Transmitting? W. F. Schaphorst. Nat. Engr., vol. 26, no. 6, June 1922, pp. 268–269, 1 fig. Simple method of determining from easily obtained instruments.

BELTING

Cellulose. Experiments With Cellulose Belting (Versuche mit Zellstofftreibriemen), M. Rudeloff. Zeit. des Vereines deutscher Ingenieure, vol. 66, nos. 19 and 20, May 13 and 20, 1922, pp. 466–469 and 491–494, 23 figs. May 13: Equipment for experiment, details of testing operation and conditions under which each test was carried out. May 20: Discusses friction in ball bearings in pulley-driven machinery; determination of useful work; records of revolution counters.

Grain Elevators. Belting Systems in Two Large Grain Elevators, D. R. Egbert. Belting, vol. 20, no. 6, June 1922, pp. 13–17, 6 figs. Reconstructed C. & N. W. elevator contains $8^1/_2$ miles of conveyor and elevator belt; New Orleans public elevator; four installations compared.

Slide Rule, Calculation by. The Improved Belt Slide Rule, Carl G. Barth. Management Eng., vol. 2, no. 6, June 1922, pp. 351–354, 2 figs. As now constructed it solves problems for three classes of belts, viz., machine, heavy countershaft, and light countershaft.

BLAST FURNACES

China. New Steel Plant is Wholly Chinese. Trans-Pacific, vol. 6, no. 4, April 1922, pp. 72–74, 1 fig. Some details of 250-ton blast furnace of Lungyen Min. Administration near Peking which is expected to make iron this spring.

Fuel Economy. The Alabama Company's No. 1 Stack Breaks Production Record on Low Fuel Consumption, H. R. Stuyvesant. Blast Furnace & Steel Plant, vol. 10, no. 6, June 1, 1922, pp. 343–346, 1 fig. Production increased 17 per cent, coke consumption decreased 30 per cent; labor force reduced 50 per cent.

BOILER FEEDWATER

Feeding Compound with. Methods of Feeding Boiler Compound With the Feed Water, W. H. Wakeman. Southern Engr., vol. 37, no. 4, June 1922, pp. 43–45, 4 figs. Description of successful application.

BOILER FIRING

Half-Gas. Improvements in Half-Gas Firing (Neuerungen an Halbgas-Feuerungen), Graafen. Braunkohle, vol. 21, no. 6, May 13, 1922, pp. 113–120 and (discussion) 120–124, 18 figs. Describes Völcker, Peretti, Bergman, and other types of firing systems.

BOILER PLATES

Strength and Elasticity. Strength and Elasticity of Boiler Plate at Elevated Temperatures, H. J. French. Chem. & Met. Eng., vol. 26, no. 26, June 28, 1922, pp. 1207–1209, 3 figs. Proportional limit maintained or increased with first temperature rise; tensile strength has slight maximum at about 250 deg. cent., but both fall off badly at higher temperatures; reduction and elongation have minimum at about 260 deg. cent., but recover their original value around 450 deg. cent.

BOILER TUBES

Safe Ends, Electric Welding. Electrically Safe Ending Boiler Tubes, J. J. Sullivan. Boiler Maker, vol. 22, no. 6, June 1922, pp. 153–154, 2 figs. Summary of results in safe ending boiler tubes and flues with Thomson electric butt welder at Nashville, Chattanooga & St. Louis Ry., Nashville, Tenn.

BOILERS

Electrically Heated. Production of Steam and Hot Water in the Electric Boiler (Dampf- und Warmwassererzeugung in elektrischen Dampfkesseln), Hindelang. Zeit. des Bayer. Revisions-Vereins, vol. 26, no. 10, May 31, 1922, pp. 84–85, 1 fig. Providing hot water to Municipal Bath and German Museum in Munich.

Fire Bridges. Arches in Central Heating Boilers (Schamotte-Einbauten in Zentralheizungs-Kesseln) de Grahl. Glasers Annalen, vol. 90, no. 12, June 15, 1922, pp. 215–221, 5 figs. Nassel fire bridge and tests made to establish its efficiency, including flue-gas analysis, determination of heat losses, etc.

Ladd-Belleville. Large Units of Modern Boiler Plants (Les grandes unités des chaufferies modernes), C. Radiguer. Révue Générale de l'Électricité, vol. 11, no. 24, June 17, 1922, pp. 897–906, 6 figs. Describes Ladd-Belleville boilers at Ford plant on River Rouge, their operation, upkeep, firing with gas and pulverized coal, etc.

[See also LOCOMOTIVE BOILERS.]

BOILERS, WATER-TUBE

Spearing, Manufacture of. The Manufacture of the Spearing Boiler. Eng. Rev., vol. 35, no. 11, May 1922, pp. 379–381, 3 figs. Facts about design, manufacture and testing of this comparatively new type.

BRASS

Forgings. Brass Forgings, C. G. Heiby. Metal Industry (N. Y.), vol. 20, no. 6, June 1922, pp. 220–221. How produced; chilled cast blanks; composition of metal; microstructure of forgings. Paper read at Convention of A.F.A.

The Development of Brass Forging, Oscar T. Roder. Forging & Heat Treating, vol. 8, no. 6, June 1922, pp. 256–259, 7 figs. Art of working brass while hot; general details of process of presses used and of die construction; composition; physical properties; microstructure of forgings and castings.

BRAZING

Dip Brazing and Heat Treatment. Dip-Brazing With 80:20 Brass and the Heat Treatment of Brazed Joints, E. V. Schaal. Chem. & Met. Eng., vol. 26, no. 24, June 14, 1922, pp. 1121–1125, 9 figs. Satis-

factory methods for dip brazing; strengths of joint and effect of heat-treatment; metallography of brazed joints; strength of bond between brass and steel.

BUSES

Trolley, Overhead Materials for. Overhead Materials and Current Collection Equipment for Trolley Bus Lines, M. W. Manz. Bus Transportation, vol. 1, no. 6, June 1922, pp. 327–330, 12 figs. Advantages of continuing use of present standards as far as practicable. Details of trolley harp, base and overhead special work design.

C

CABLEWAYS

Aerial. The Use of Electric Telphers for Conveying, in Dock Operations (Die Verwendung der Elektrohangebahn im Hafenbetrieb), Martin Bruckmann. Schiffbau, vol. 23, no. 37, June 14, 1922, pp. 1086–1092, 16 figs. Mechanical conveying by means of aerial cables, electric telphers, and cable cranes, and their operation in loading and unloading ships.

CANS

Seaming, Special Machines for. Building Special Machines for Can-Seaming, Arthur Mumper. Machy. (N. Y.), vol. 28, no. 11, July 1922, pp. 899–902, 3 figs. Highly developed type of single-purpose machine which closes ends of cylindrical tin containers.

CAR CONSTRUCTION

Side Frame. A One Piece Wrought Steel Truck Side Frame. Ry. Rev., vol. 70, no. 24, June 17, 1922, pp. 918–920, 6 figs. Symington type which is sheared and formed under hydraulic press; electric welded in final form.

CAR LIGHTING

Generator, Direct-Drive. Direct Driving Axle Generators for Passenger Cars. Ry. Rev., vol. 70, no. 25, June 24, 1922, pp. 972–974, 5 figs. Am. Ry. Assn. committee on train lighting and equipment report direct drive still in development stage. (Abstract.)

Generator, Body Suspension. Long Island Changes Generator Suspensions. Ry. Elec. Engr., vol. 13, no. 6, June 1922, pp. 190–192, 2 figs. Truck mounted machines placed on car bodies show economy by giving greater belt mileage.

CARS

Dump. Car Tippers and Automatic Unloading Cars (Wagenkipper und Selbstentladewagen), Wintermeyer. Verkehrstechnik, vol. 39, no. 23, June 9, 1922, pp. 317–320, 10 figs. Principles of construction of cars for coal, coal, ore, sand and similar material; automatic unloading to keep cars in circulation.

CARS, COAL

N. & W. Ry., 120-Ton. Coal Car of 120-Tons Capacity—Norfolk and Western Railway. Ry. & Locomotive Eng., vol. 35, no. 6, June 1922, pp. 142–145, 7 figs. Details of construction and design.

CASE-HARDENING

Distortion. Distortion Produced in Casehardening, A. A. Blue. Am. Mach., vol. 56, no. 25, June 22, 1922, pp. 915–916, 3 figs. Consistent minimum warpage in manganese steel; large holes decrease, small holes increase when carbonized; greater wall thickness produces greater effect.

Steel, Failures. Causes of Failures in Case-Hardening Steel. Iron Age, vol. 109, no. 26, June 29, 1922, pp. 1807–1808. Non-metallic impurities, chiefly dissolved oxides, responsible in many cases in which hardening process has been thought at fault.

Selective. Selective Case-Carburizing, W. P. Wood and O. W. McMullan. Chem. & Met. Eng., vol. 26, no. 23, June 7, 1922, pp. 1077–1080, 4 figs. Review of various methods of producing local cases; in general, electrodeposited copper has furnished best protection; non-metallic coating whose application and removal presents no great difficulties is described.

CAST IRON

American vs. British. American Versus British Grey Cast Iron, F. J. Cook. Can. Foundryman, vol. 13, no. 6, June 1922, pp. 26–32, 7 figs. Superior qualities of British iron shown; sulphur and phosphorus not as detrimental as generally believed; soft castings depreciate value of American machinery.

CASTINGS

Centrifugal. Centrifugal Castings, N. Lilienberg. Blast Furnace & Steel Plant, vol. 10, no. 7, July 1922, pp. 375–379, 9 figs. States advantages of making centrifugal castings in vertical molds rather than in horizontal molds as is customary; theoretical calculations necessary for method are given.

Cutting and Welding. Cutting and Welding of Castings, G. O. Carter. Iron Trade Rev., vol. 71, no. 2, July 13, 1922, pp. 107–110. Minimum interruption caused by changing of tips, altering of pressures, etc.; castings should be segregated according to size of risers. Paper read before Am. Foundrymen's Convention.

Feeding Heads, Without. The Making of Castings Without Feeding Heads, E. Ronceray. Foundry Trade Jl., vol. 25, no. 302, June 1, 1922, pp. 393–397. Suggestions of importance in practice which would obviate necessity for heads in many cases. Paper read before Inst. British Foundrymen.

Plaster Molds for. Plaster Molds for Small Castings. Machy. (Lond.), vol. 20, no. 509, June 29, 1922, pp. 398–399, 2 figs. Advantageous features for models and exacting commercial work.

CEMENT MANUFACTURE

Fusion Process. Possibilities of Fusion Process for Cement Production, S. L. Meyers. Concrete, vol. 20, no. 6, June 1922, pp. 105–107, 5 figs. This process contains fuel economy possibilities that rotary kiln with sintering methods does not.

CEMENT MILLS

Iowa. Building and Operating Iowa's First Cement Plant, W. T. Christine. Cement, Mill & Quarry, vol. 20, no. 10, May 20, 1922, pp. 25–34, 19 figs. Plant was put into operation in 1908; intricate process of cement manufacture; waste-heat boiler furnishes all power to operate plant.

CEMENT, PORTLAND

Chemical Analysis. Interpreting the Chemical Analysis of Portland Cement, J. C. Witt. Cement & Eng. News, vol. 34, no. 6, June 1922, pp. 21–23. Suggested system of recasting has not demonstrated relationship of results with physical behavior.

CENTRAL STATIONS

Superpower. The Superpower Undertaking in Styria (Austria) (Das steirische Grosskraftwerksunternehmen), Richard Hofbauer. Elektrotechnik u. Maschinenbau, vol. 40, no. 23, June 4, 1922, pp. 265–269. Discusses power works of Enns group, Mur groupe, water storage works at Teigitsch and Mixnitz, and districts they supply with power.

CLUTCHES

Magnetic. Magnetic Clutches in the Cement Industry, W. H. Costello. Cement, Mill & Quarry, vol. 20, no. 11, June 5, 1922, pp. 23–24. Transmits from 600 to 800 hp. Torque requirements; starting tube mill; shaft alignment.

COAL

Briquetting. Briquetting of Peat (Brikettierung von Rohtorf oder Kohlenschlamm durch maschinelle Druckentwässerung ohne Bindemittel), Kampers. Technische Blätter, vol. 12, no. 5, Feb. 4, 1922, pp. 49–51, 4 figs. Processes depending on extracting water by pressure.

Production Costs. Analyzing the Cost of Producing Anthracite, S. D. Warriner. Min. & Metallurgy, no. 187, July 1922, pp. 7–9. Explanation of wide difference in price to consumer from labor cost in mine.

Steaming. Coal Steaming, A. W. Binns. Power Plant Eng., vol. 26, no. 12, June 15, 1922, pp. 595–598, 8 figs. Costs, steam consumption and mechanical details.

COAL HANDLING

Equipment for Ash and. On Coal and Ash Handling Equipment, Harry R. Westcott. Power House, vol. 15, no. 10, May 20, 1922, pp. 25–29 and 42. Numerous types of apparatus for these purposes are described in outline, and suitability of one or other is indicated under differing conditions.

COKE

Non-Coking Coals. Coke from "Non-Coking" Coals. Iron & Coal Trades Rev., vol. 104, no. 2828, May 12, 1922, pp. 708–709. Process of heating non-coking coals so rapidly that resinous content is decomposed before excessive oxidation occurs.

COMPRESSED AIR

Interfactory Mail Despatch. Development of Flat Postal Tubes for Conveying Sheets of Paper to Distant Departments (Die Entwicklung der Flachrohrpost fur die Beförderung von Zetteln in Fernämtern), Carl Beckmann. Ziet. für Fernmeldetechnik Werk- und Gerätebau, vol. 3, no. 5, May 16, 1922, pp. 77–82, 21 figs. System of pneumatic conveying which does without condensers, documents being conveyed direct by air to distant parts of factory.

COMPRESSORS

See AIR COMPRESSORS.

CONCRETE

Alkali Action. The Effect of Alkali Upon Concrete, S. H. McCroy. Cement & Eng. News, vol. 34, no. 6, June 1922, pp. 17–18. Decomposition caused and explanations of it offered. No method known of preventing such deterioration, but impermeability retards it. Recommendations as to aggregate, proportioning and placing of concrete.

Lumber. Concrete Lumber Industry Is Growing, W. A. Scott. Concrete Products, vol. 22, no. 6, June 1922, pp. 29–31, 8 figs. Company in California has developed system of manufacture which is leased in assigned territory.

CONCRETE CONSTRUCTION, REINFORCED

Calculation. Reinforced-Concrete Construction Work and Calculations (Rechnung und Konstruktion im Eisenbetonbau), Robert Otzen. Bauingenieur, vol. 3, no. 9, May 15, 1922, pp. 262–266, 1 fig. Methods of calculating cross sections, stresses, etc., develops formulas and gives examples of application.

CONDENSERS, STEAM

Air Pumps for. The C. M. and M.-Delas Air Extractor. Electrician, vol. 88, no. 2300, June 16, 1922, pp. 718–719, 3 figs. Results of tests made in Paris workshops of Société Condenseurs Délas.

Tube Packing. Condenser Tube Packing. Am. Mar. Engr., vol. 17, no. 6, June 1922, pp. 25–31, 17 figs. Underlying causes of corrosion and an easy economical solution of problem.

COOLERS

Live-Steam. Live-Steam Coolers (Heissdampf-Kühlapparate). Archiv fur Wärmewirtschaft, vol. 3, no. 5, May 1922, pp. 91–92, 4 figs. Describes cooler built by Sieffert & Co., A. G., for cooling live steam to be used in manufacturing where waste-steam supply is insufficient.

CORES

Machines for Manufacture of. Production of Cores by Means of Machines (Die Herstellung von Kernen mettels Maschinen), Georg Hoffmann. Giesserei-Zeitung, vol. 19, nos. 13 and 15, Mar. 28, and Apr. 11, 1922, pp. 199–203 and 241–245, 33 figs. Mar. 28: Detailed description of American and hydraulic core machines. Apr. 11: Describes large and small types of core-making machines.

CORROSION

Iron and Steel. Corrosion of Iron and Steel—Influence of Molecular Concentration on Immersion-Test Investigations, D. M. Strickland. Chem. & Met. Eng., vol. 26, no. 25, June 21, 1922, pp. 1165–1169, 1 fig. Initial rate of corrosion most important; since solution rates change as equilibrium approaches; spent solutions often harmless, but sometimes accelerate corrosion; short tests in circulating pure chemicals logical method for comparative tests.

COST ACCOUNTING

Concrete Products Industry. Cost Accounting in Products Manufacture, Mac Hanson. Concrete, vol. 20, no. 6, June 1922, pp. 235–238, 3 figs. Relation of management to profits; valuable system which is being used and requires only few hours per week for usual product plant.

COTTON

English and American Practice. Cotton Manufacture, Sidney B. Paine. Engrs. & Eng., May 1922, pp. 149–153 and (discussion) 153–154. Conditions under which English textile industry has been developed; difference between English and American practice; suggestions toward adoption of English details which have proved profitable.

CRANES

Hammerhead, 200-Ton. Two-Hundred-Ton Fitting Out Crane at Camden Yard. Mar. Eng., vol. 27, no. 6, June 1922, pp. 383–385, 4 figs. Details of construction and operation of huge electrically operated hammerhead crane installed at South Yard of N. Y. Shipbldg. Corp.

CUPOLAS

Charging Machines. Charging Machines for Cupolas. Engr., vol. 133, no. 3470, June 30, 1922, pp. 727–728, 5 figs. Design of Thwaites Bros., Ltd., Bradford, which combines comparative low first cost and ease of installation.

Operation. Cupola Furnace Operations, Requirements in Coke and Its Influence in Enriching the Melt in Sulphur (Der hochentwickelte Kupolofenbetrieb, sein Koksbedarf und sein Einfluss auf die Schwefelanreicherung der Schmelze), Hörnig. Giesserei-Zeitung, vol. 19, no. 14, Apr. 4, 1922, pp. 215–220, 6 figs. Discusses modern cupola furnace with air preheater, and its operation.

CUTTING METALS

Cutting Fluids for. Cutting Fluids, Eugene C. Bingham. Am. Mach., vol. 56, no. 26, June 29, 1922, pp. 958–961, 4 figs. Why adhesion is important lubrication factor; relative physical properties found by tests; best oil for each operation and material. (Abstract.) Tech. Paper No. 204, Bur. of Standards.

D

DIESEL ENGINES

Air Supply. Air for Diesel Engine-Installations, W. P. Sillince. Oil Eng. & Finance, vol. 1, nos. 11 and 13, Mar. 25 and Apr. 8, 1922, pp. 370–371 and 439–440. Survey of air for combustion of fuel, for starting and maneuvering engines, for injection of fuel and to operate auxiliaries.

Compressorless. Compressorless Diesel Engines (Kompressorlose Dieselmaschinen). Schiffbau, vol. 23, no. 36, June 7, 1922, pp. 1055–1057, 7 figs. Discusses Trinkler, Haselwander, and other types, which do without compressor for feeding of fuel.

Construction and Operation. Diesel and Semi-Diesel Engines (Moteurs Diesel et Semi-Diesel), Ed Allar. Bul. des Associations Françaises de Propriétaires d'Appareils a Vapeur, vol. 3, no. 8, Apr. 1922, pp. 86–105, 5 figs. Theory, principle of combustion, construction, operation, and application.

Petroleum as Fuel. Some Characteristics of Petroleum Oils Used On Diesel Engines, Harold Moore. Oil Eng. & Finance, vol. 1, no. 14, Apr. 15, 1922, pp. 458–460 and 463–464. Number of analyses of fuel oils from various sources and their value as means of predicting behavior of new oils of similar characteristics. Paper read before Diesel Engine Users Assn.

Tosi. Internal-Combustion Engines (Les moteurs a combustion interne). Génie Civil, vol. 80, no. 25, June 24, 1922, pp. 561–564, 7 figs. Compares two-stroke and four-stroke Diesel engines, their application for marine purposes, and describes in detail Tosi Diesel four-stroke engine.

DURALUMIN

Gearing, for. Duralumin for Gearing, Robert W. Daniels. Am. Mach., vol. 57, no. 2, July 13, 1922, pp. 62–65. History of duralumin; some properties

that make it desirable for worm and other gearing, its strength and wearing qualities.

DUST

Precipitation, Electrical. Electrical Precipitation of Dust and Its Application in the Purification of Gas (La précipitation électrique des poussières), Saget. Bul. de la Societe Française des Electriciens, vol. 2, no. 12, Feb. 1922, pp. 83-100, 6 figs. Discusses precipitation in metallurgical, sulphuric acid and other plants, and advises its more general adoption.

DYNAMOMETERS

Tractor, Recording Type. The Watson Dynamometer, George W. Watson. Engineering, vol. 113, no. 2948, June 30, 1922, pp. 814-816, 10 figs. Tractive force transmitted by oil pressure in one cylinder to spring-actuated piston in smaller cylinder. Link motion controls stylus recording on paper roll actuated by speed of tractor. Time and furrow depth also recorded.

E

ECONOMIZERS

Value of. The Case for the Economizer, Julius Frith. Engineer, vol. 133, no. 3468, June 16, 1922, pp. 655-656, 3 figs. Rigid application of first principle usually shows coal economy but not always reduction of operating costs and features which influence this result.

EDUCATION, ENGINEERING

Technical Literature, Use of. Instruction of Students in the Use of Technical Literature, an Unexploited Phase of Engineering Education, E. H. McClelland. Eng. & Contracting, vol. 57, no. 25, June 21, 1922, pp. 598-600. Importance of research in present-day manufacture and available literature from which to start.

ELASTICITY

Moduli. The Modulus of Elasticity in Mechanical Construction Work (Le rôle du module d'élasticité dans la construction mécanique), R. de Fleury. Revue de Metallurgie, vol. 19, no. 5, May 1922, pp. 295-302. Its application to malleable iron, aluminum bronzes and other light metals, and construction of Diesel, aeronautical, and automobile engines.

ELECTRIC FURNACES

Design. New Electric Furnaces for Temperatures of 2500 Degrees and Over (Neuartige elektrische Öfen für Temperaturen von 2500° und darüber), E. Löwenstein. Centralblatt für Mineralogie, Geologie und Paläontologie, no. 9, May 1, 1922, pp. 283-285, 3 figs. Describes furnace built by Göttinger Elektroschaltwerk, in which high temperatures can be reached quickly, temperatures can be accurately regulated, current consumption is small; suitable for metals and minerals, and difficultly fusible earths of all kinds.

Fiat. Development of the Italian Iron Industry by Extensive Use of Electric Power in Smelting Works (Ueber die Entwicklung der italienischen Eisenindustrie durch weitgehende Anwendung elektrischer Energie im Schmelzbetrieb), Dornhecker. Stahl u. Eisen, vol. 42, no. 22, June 1, 1922, pp. 845-848, 3 figs. Discusses electric furnaces in iron foundries, especially Fiat furnace, and works of Fiat Co.

ELECTRIC LAMPS, INCANDESCENT

Dangers. Danger of Touching Unclean Incandescent Bulbs (Gefährdungsmöglichkeiten bei Berührung unsauberer Glühlampen), Stefan Jellinek. Elektrotechnische Zeit., vol. 43, no. 24, June 15, 1922, pp. 815-817, 4 figs. Discusses case of a death resulting from touching glass bulb covered with lime spots. Very considerable potentials were found by making contact with unclean bulbs.

ELECTRIC LOCOMOTIVES

British Design. Electric Locomotives, Vincent L. Raven. Ry. Gaz., vol. 36, no. 25, June 23, 1922, pp. 994-996, 2 figs. Design of shunting, freight and passenger locomotives. Foreign practice in relation to British conditions. Summary of paper read before Instn. Mech. Engr.

Mechanical Parts. Mechanical Parts of Electric Locomotives, H. A. Houston. Ry. Mech. Engr., vol. 96, no. 6, June 1922, pp. 319-322, 12 figs. Comparison with steam locomotives; details of construction of outside-frame type.

ELECTRIC PLANTS

Turbo-Alternator. Some Notes on the Design of Generating Plant, C. F. Hewitt. Elec. Times, vol. 61, no. 1599, June 8, 1922, pp. 552-553. Reliability; working conditions; thermal economy, capital cost, ease of operation and general accessibility are design factors in order of their importance.

ELECTRIC WELDING

Apparatus. Electric Welding Installations (Elettrische Schweissanlagen), Karl Midsch. Metall-Technik, vol. 48, no. 19, May 4, 1922, pp. 205-208, 10 figs. Discusses electric arc, resistance, and spot welding, and explains operations and apparatus.

Development. The History of the Development o Electric Welding, J. M. F. Wilson. Elec. News, vol. 31, nos. 7 and 11, Apr. 1 and June 1, 1922, pp. 35-37 and 40-41, 3 figs. Discusses carbon-electrode and metal-electrode systems of welding, selection of electrodes; impurities, etc.

Ship Construction. Electric Welding Applied to Steel Construction With Special Reference to Ships, A. T. Wall. Instn. Mech. Engrs. Prac., no. 2, 1922, pp. 239-288, 19 figs. Review of present application to ship construction and indication of further possibilities in steel structures.

Shipyards, Germany. Electric Arc Welding in the German Shipyard at Hamburg (Die elektrische Lichtbogenschweissung auf der Deutschen Werft, Hamburg), W. Heins. Schiffbau, vol. 23, no. 36, June 7, 1922, pp. 1062-1066, 14 figs. Gives a number of examples of handy application.

ENAMELS

Coating. Microscopic Study of Ground Coat and Cover Coat Enamel Reactions, E. E. Geisinger. Am. Ceramic Soc. Jl., vol. 5, no. 6, June 1922, pp. 322-337, 13 figs. Study showing that susceptibility of enamels to furnace gases is easily classified by cross section under microscope, examples.

ENERGY

World, Economics of. A Swedish Scientist on the World Energy Economics, Svante Arrhenius. Eng. Progress, vol. 3, no. 6, June 1922, pp. 136-138. Consideration of sources of energy which are still available and how long they are likely to last.

ENGINEERING SCHOOLS

Germany. Illuminating Institute Department of the Baden Technical High School at Carlsruhe (Das Lichttechnische Institut der Badischen Technischen Hochschule in Karlsruhe), J. Teichmuler. Zeit. für Beleuchtungswesen, vol. 28, no. 9-10, May 15-31, 1922, pp. 51-55, 9 figs. Series of articles describing building and equipment, curriculum at high school, photometry, diffusion of light, etc.

ENGINEHOUSES

Equipment. Expediting Enginehouse Work at Hoboken. Ry. Mech. Engr., vol. 96, no. 6, June 1922, pp. 301-304, 8 figs. Modern machine equipment and efficient labor-saving devices show good results at D. L. & W. enginehouse.

EXHAUST STEAM

Superheating for Textile Process Work. Textile Plant Superheats Exhaust Steam for Process Work, Power, vol. 55, no. 25, June 20, 1922, pp. 965-966, 2 figs. Easton Finishing Co's method of drying cloth in tentering machine and heating drying rolls.

EXPLOSIVES

C. P. Toluene. Report on the Manufacture of C. P. Toluene from By-Products Plants and Petroleum Distillates, W. K. Kirby. Alumini Mag. of Colorado School of Mines, vol. 12, no. 2, June 1922, pp. 5-10. Description of toluene and its production by scrubbing coal or water gas and synthetic process by cracking petroleum distillates.

Detonators, Lead Plate Test. The Lead Plate Test as Applied to Commercial Detonators, Bennett Grotta. Chem. & Met. Eng., vol. 26, no. 24, June 14, 1922, pp. 1126-1132, 12 figs. Tests and experiments demonstrating its value in grading commercial detonators according to well-defined standards; efficiency of commercial detonators.

Liquid Air. Use of Liquid Air as an Explosive (Empleo de oxigeno liquido como explosivo), Eduardo Carvajal. Revista Minera, Metalurgica y de Ingenieria, vol. 73, no. 2829, Apr. 24, 1922, pp. 230-233, 3 figs. Making of cartridges; comparative costs; method of operation.

F

FANS

Forced-Draft, Operating Characteristics. Operating Characteristics of Forced-Draft Fans, H. E. Corl. Power, vol. 55, no. 26, June 27, 1922, pp. 1012-1013, 2 figs. Recent developments due to underfeed stokers; new type of fan in which maximum hp. is only approximately 5 per cent higher than rated hp.

Output and Efficiency. The Characteristic Curves of Fans, and Their Application to Pre-determine the Output and Efficiency of Fans Working Singly and In Parallel On Various Resistances, Joseph Parker. Instn. Min. Engrs. Trans., vol. 63, part 3, May 1922, pp. 222-234, 11 figs. Brief consideration of a comprehensive view of all laws brought into operation by two fans working in parallel. See also Min. Inst. of Scotland Trans., vol. 43, Apr. 22, 1922, pp. 22-34, 11 figs.

FIRE PREVENTION

Building Materials Tests. Lessons of Fire Tests, S. H. Ingberg. Clay Worker, vol. 77, no. 7, June 1922, pp. 657-660, 5 figs. partly on p. 661. Brick as fire-resisting material and some results of tests on steel and concrete columns subjected to fire conditions. Paper read before Nat. Brick Mfrs. Assn. convention.

Reinforced Concrete Slab Tests. British Fire Tests on Reinforced Concrete Slabs. Indian Eng., vol. 71, no. 20, May 20, 1922, pp. 278-279, 5 figs. on supp. plate. Dept. of Sci. and Indus. Research four-hour tests, maximum temperature 2000 deg. fahr., followed by 5 min. water application.

FLOORS

Concrete. Hardening Concrete Floors, Edward D. Boyer. Cement & Eng. News, vol. 34, no. 6, June 1922, p. 28. Sometimes defects in workmanship make use of remedies advisable.

FLOW OF WATER

Pipe-Capacity Chart. Chart That Solves Pipe-Capacity Problems, W. F. Schaphorst. Coal Age, vol. 21, no. 24, June 15, 1922, pp. 999-1000, 1 fig. Chart from which velocity that water will travel through a pipe of given diameter may be quickly determined in cu. ft. gals. or lb. per min.

FLOUR MILLS

Machinery. The Machinery of Flour Milling. Eng. Rev., vol. 35, no. 11, May 1922, pp. 370-376, 7 figs. Economics, mechanical aids, cleaning grain, some types of mills.

FLUE-GAS ANALYSIS

Graphical, Use of. New Diagrams for Turning to Account Fuel and Flue Gas Analyses (Neue Schaubilder zur Auswertung von Brennstoff- und Rauchgasanalysen), Wilhelm Schultes. Warme, vol. 45, no. 17, Apr. 28, 1922, pp. 213-218, 7 figs. Shows how flue gas analyses of fuels of known composition can be made use of by means of diagrams and graphic calculations, diagrams for classification of fuels.

FORGING MACHINES

Germany. Recent Forging Machines and Their Application (Neuzeitliche Schmiedemaschinen und ihre Anwendung), Technische Blatter, vol. 12, no. 1, Jan. 7, 1922, pp. 1-3, 13 figs. Discusses machines, especially for research work, railroad shops, and hardware generally.

FOUNDRY EQUIPMENT

Compressed Air. Compressed Air Applied to the Foundry, R. Hoadley Tingley. Compressed Air Mag., vol. 27, no. 6, June 1922, pp. 153-158, 20 figs. Description of some of many air appliances indispensable in modern foundry practice.

[See also CORES.]

FUELS

Coal and Oils. Relative Value of Coal and Oils as Fuels, C. H. Butz. Forging & Heat Treating, vol. 8, no. 6, June 1922, pp. 262-265, 6 figs. Comparison made by means of charts based upon practical operating figures obtained from processes varying in nature from very inefficient furnace to highly efficient boiler.

Utilization on Railways. Utilization of Fuels on Railroads—6th Report of the Commission for the Utilization of Fuels (L'Utilisation des combustibles sur les chemins de fer—Sixieme rapport de la Commission d'utilisation des combustibles). Génie Civil, vol. 80, no. 20, May 20, 1922, pp. 449-453. Effect of electrification of railway lines; character and performance of steam locomotives; production and use of steam; etc.

[See also AUTOMOBILE FUELS, COAL, COKE, GASOLINE, OIL FUEL, PULVERIZED COAL.]

FURNACES, BOILER

Care and Upkeep. Views of Mechanical Engineers in Wyoming Valley as to Proper Care and Upkeep of Boiler Furnaces, D. C. Ashmead. Coal Age, vol. 21, no. 26, June 29, 1922, pp. 1083-1087, 3 figs. Anthracite boiler practice inefficient; some plants install Dutch ovens; combustion arches increase temperature and steadiness of heat; large-size fuel may ruin arches; water softening much needed; fireclay as a mortar.

FURNACES, HEATING

Fuel Economy. Fuel Economy in Heating Furnaces, K. Huessener. Blast Furnace & Steel Plant, vol. 10, no. 7, July 1922, pp. 380-383, 2 figs. New methods to obtain increased production with decreased fuel consumption from regenerative and recuperative furnaces.

G

GAGES

Gage Blocks. Interference Methods for Standardizing and Testing Precision Gage Blocks, C. G. Peters and H. S. Boyd. Scientific Papers Bur. of Standards, no. 436, May 2, 1922, pp. 677-713, 21 figs. Use of interference of light waves makes possible detection of errors within a few millionths of an inch.

Wear, Allowing for. Allowing for Gage Wear, R. Dumas and E. C. Peck. Am. Mach., vol. 56, no. 26, June 29, 1922, pp. 953-954. Discussion of desirability of having fixed tolerance or an allowance for wear; difference of American and British viewpoints.

GALVANIZING

Heat Transmission in. Heat Transmission in the Hot-Galvanizing Process, J. D. Keller. Blast Furnace & Steel Plant, vol. 10, no. 7, July 1922, pp. 371-373, 2 figs. Describing thermal features of process; rate of motion of sheets through bath should vary with sheet thickness if based on factor of heat transmission.

GARAGES

Ramp and Elevator Type. Comparison of Ramp and Elevator Type Garages, Harold F. Blanchard. Bus Transportation, vol. 1, no. 6, June 1922, pp. 331-335, 12 figs. Description of comparative capacities and convenience.

GAS CLEANING

Filtering Process. A New Process For Scrubbing Gases and Vapours, E. Stach. Eng. Progress, vol. 3, no. 6, June 1922, pp. 127-130, 7 figs. Rotary filtering process by Freytag-Messler for removing dust, tar, oil, and other impurities more completely than hitherto.

GAS ENGINES

Navy, Building for. Building Gas Engines for the Navy, S. W. Brinson. Am. Mach., vol. 57, no. 2, July 13, 1922, pp. 45-48, 9 figs. Developing engine

and special plant; equipment of shop; machining engine parts; handling work; assembling engine.

GAS PRODUCERS

Seaboard By-Product Coke Plant. Producer Gas for By-Product Ovens, Freeman D. Lohr. Gas Age-Rec., vol 49, no. 22, June 3, 1922, pp. 677–681, 8 figs. Description of new plant built to meet increasing demand for gas and decreasing market for coke.

GASOLINE

Cracking Process. Production of Gasoline by Cracking Heavier Oils, E. W. Dean and W. A. Jacobs. Petroleum World, vol. 19, no. 261, June 1922, pp. 225–226 and 228–230, 1 fig. Pressure-distillation and vapor-phase processes; experiments and methods resulting from same. See also Petroleum Times, vol. 7, nos. 180 and 181, June 17 and 24, 1922, pp. 874–875 and 915.

High-Explosive, Process for. New Process Makes High-Explosive Gasoline. Oil Trade Jl., vol. 13, no. 6, June 1922, p. 15. Wm. J. Knox perfects invention which will increase percentage of distillate recovered from crude on large scale.

GEAR-CUTTING MACHINES

Geometric Control. Geometric Control of Gear Cutter Movement, Chester B. Hamilton, Jr. Can. Machy., vol. 27, no. 22, June 1, 1922, pp. 40–41 and 48, 4 figs. Careful grinding of cutters is necessary to maintain proper shape; using mill type of cutter; machines for cutting double-helical gears are of special design.

Spur, Muir Automatic Machine. The Muir Automatic Spur Gear Generating Machine. Machy. (Lond.), vol. 20, no. 506, June 8, 1922, pp. 292–294, 4 figs. Teeth of spur gears are formed with rack-shape cutter which has vertical reciprocating motion across face of gear blank.

Fellows High-Speed Shaper. New Fellows High-Speed Gear Shaper. Machy. (Lond.), vol. 20, no. 507, June 15, 1922, pp. 329–332, 6 figs. Machine that operates with a shaping action and generates gear teeth from gear-shape cutter.

Spur, Hobbing. Cutting Spur Gears by Hobbing. Machy. (Lond.), vol. 20, no. 509, June 29, 1922, pp. 393–398, 5 figs. Setting up gear-hobbing machines; examples from practice; application of multiple-threaded hobs; cutting small pinions.

GEARS

Autopitch. A New Form of Gear. Eng. Production, vol. 4, no. 88, June 8, 1922, pp. 545–548, 24 figs. Development of new type of gear as an attempt to reach requirements of theoretically ideal one; description of extent to which attempt is successful. Abridgment of paper read before Instn. of Engrs. & Shipbuilders.

Helical and Spur. Helical Gears and Spur Gears, W. G. Dunkley. Machy. (Lond.), vol. 20, nos. 500 and 506. Apr. 27 and June 8, 1922, pp. 105–107 and 300–302, 9 figs. April 27: Effect of sliding action on uniform velocity and on relative efficiency. June 8: Contact conditions of spur gears; load distribution and periodical variations; effect of variation of load distribution on uniformity of rotation; effect of increased speed.

GLASS

Composition and Durability. An Examination and Extension of Zulkowski's Theory of the Relation between the Composition and Durability of Glasses, Wm. L. Baillie. Soc. of Glass Technology Jl., vol. 6, no. 21, May 1922, pp. 68–95 and (discussion) 95–101, 1 fig.

GRINDING

Automobile Parts. Grinding in the Automotive Industry. Machy. (N. Y.), vol. 28, no. 11, July 1922, pp. 855–862, 16 figs. Approved methods of grinding such important parts as pistons, piston-rings, piston-pins, cylinders, connecting-rods, crankshafts, camshafts, gear teeth and spline shafts.

H

HANDLING MATERIALS

Safety in. Making Material Handling Safe, Vernon C. King. Iron Trade Rev., vol. 71, no. 1, July 6, 1922, pp. 29–32, 8 figs. Greatest number of industrial accidents occur in handling of material; use of proper trucking and conveying equipment is aid to safety; discipline and morale are essential factors. Paper presented before Worcester Sec. A.S.M.E.

[See Also COAL HANDLING.]

HANGARS

Airplane. The New Airplane Hangars at the Aerial Port of Bourget, Near Paris (Les nouveaux hangars a avions du port aérien du Bourget, près Paris), Ch. Dantin. Génie Civil, vol. 80, no. 21, May 27, 1922, pp. 465–468, 13 figs. partly on supp. plate. General description of five hangars used by Messageries aériennes Co., Grands Express aériens Co., Franco-Roumaine Co., and Aérienne Française Co.; details of construction.

HARDNESS

Testing. The Ball Hardness Test, Dr. Moore. Metal Industry (Lond.), vol. 20, no. 22, June 2, 1922, pp. 510–513, 1 fig. Indentation tests being purely empirical should specify conditions. Features of Brinell test and Meyer's laws. Paper presented before Inst. of Metals

HEAT TRANSMISSION

Cylinder Walls. Heat Transmission Through Cylinder Walls of Internal-Combustion Engines (Wärme Durchgang durch die Zylinderwandungen von Verbrennungs-Maschinen), Schlachter. Motor u. Auto, vol. 19, nos. 7, 8 and 9, May 1, 10 and 20, 1922, pp. 97–100, 113–116 and 129–131, 8 figs. Discusses transmission of heat from one medium to another, and develops formula for calculation; transmission of heat from gas to metal walls; examines heat transmission on mathematical basis.

Measurement. American Heat Transmission Measurement by the Two-Plate System (Amerikanische Wärmedurchgangsmessungen nach der Zweiplattenmethode), Max Jakob. Zeit. für die gesamte Kälte-Industrie, vol. 29, no. 5, May 1922, pp. 83–87, 3 figs. Recent work carried out by Bur of Standards and Am. Soc. Heat. & Vent. Engrs.

HEATING AND VENTILATING

Cleveland Public Auditorium. Ventilating Equipment of Cleveland's Public Auditorium, M. A. Boyd. Heat. & Vent. Mag., vol. 19, no 6, June 1922, pp. 33–40, 9 figs. Methods followed in handling air supply for largest plastered structure in world.

HEATING, STEAM

Building Heating Plant. World's Largest Gas Heating Plant, S. S. Fyfe. Gas Age-Rec., vol. 49, no. 25, June 24, 1922, pp. 765–768, 3 figs. Gas-fired steam boilers at Los Angeles; heats building of 3,000,000 cu. ft., using mixed natural and artificial gas.

General Fire Extinguisher Co. Heating System of the General Fire Extinguisher Co., Chas. L. Hubbard. Power Plant Eng., vol. 26, no. 12, June 15, 1922, pp. 591–595, 10 figs. Steam is generated at high pressure and used only for heating. Power is purchased from an outside source.

HOISTING ENGINES

Steam and Air Combination. Combination Steam and Air Hoist, R. C. Demary. Nat. Engr., vol. 26, no. 6, June 1922, pp. 244–246, 5 figs. Description of twin tandem compound with Corliss-type valve gear; high-pressure cylinders which are used for compressing air.

HOISTS

Skip. Elevating Coke by Skip Hoist. Gas Age-Rec., vol. 49, no. 22, June 3, 1922, pp. 683–684 and 687, 5 figs. Taking coke from small cars to elevated bins by means of automatic device; straight-up lift eliminates consideration of belt conveyor.

HYDRAULIC TURBINES

Impellers. Minimum Number of Blades and Inlet Diagram of Modern Turbine Impellers (Die Minimalschaufelzahl und das Eintrittsdiagramm für moderne Stauturbinenlaufräder), Hugo Marschner. Zeit. des Österr. Ingenieur- u. Architekten-Vereines, vol. 74, no. 15–16, Apr. 14, 1922, pp. 67–69, 6 figs. Present turbine systems; arrangement of rotating blades, and calculation of minimum number; minimum space between blades.

Radial Suction. Radial Suction Turbines (Die Saugstrahlturbine), Hans Baudisch. Elektrotechnik u. Maschinenbau, vol. 40, no. 25, June 18, 1922, pp. 289–291, 1 fig. Calculation of useful work, losses due to friction and eddies, comparison with Kaplan turbine, etc.

HYDROELECTRIC PLANTS

France. Hydroelectric Plant of Baumont-Monteaux (Usine hydro-électrique de Beaumont-Monteux), J. Reyval. Révue Générale de l'Électricité, vol. 11, no. 21, May 27, 1922, pp. 781–790, 17 figs. A central station situated at confluence of Isère and Rhone; will supply current to industrial works; general description of parts of plant and engineering work connected with it

Hydroelectric Plant of Beaumont-Monteaux (Usine hydro-électrique de Beaumont-Monteux), Jacques Suet. Révue Générale de l'Électricité, vol. 11, no. 22, June 3, 1922, pp. 817–829, 18 figs. Describes electric equipment, including alternators, exciters, transformers, switchboard; current is stepped from 5,500 to 120,000 volts.

New Brunswick. New Hydro Plant in New Brunswick. Elec. News, vol. 31, no. 11, June 1, 1922, pp. 34–39, 9 figs. Unique installation just completed at Musquash River, near St. John; actually two plants in one; work of New Brunswick Power Commission.

Queenston-Chippawa, Canada. Arrangement for Handling 500,000-Kw. Load from Queenston Plant. Elec. World, vol. 79, no. 25, June 24, 1922, pp. 1261–1263, 2 figs. Most economical utilization of water power available and protection against interruption of service were chief factors influencing design of this new station of Hydroelectric Power Commission of Ontario.

Queenston-Chippawa Hydro Development Largest in the World. Power, vol. 55, no 26, June 27, 1922, pp. 1000–1006, 9 figs. Initial installation five 55,000-hp. hydroelectric units; 305 ft. of 327-ft. head between Lake Erie and Lake Ontario effective on turbines; water carried through concrete-lined canal designed for possible ultimate capacity of 600,000-hp.

Semi-Outdoor. Semi-Outdoor Hydro-Electric Plant with Backwater Suppressor, John A. Sirnit. Elec. World, vol. 79, no. 23, June 10, 1922, pp. 1161–1164, 5 figs. Mitchell Dam development of the Alabama Power Company will involve an entirely new principle in hydroelectric construction. Results of long series of experiments in backwater suppression.

Switzerland. Hydroelectric Plant of Fully (Valais, Switzerland) Using a Head of 1,650 m. [Usine hydro-électrique de Fully (Vailis, Suisse), utilisant une chute de 1.650 mètres], Ch. Daotin. Génie Civil, vol. 80, nos. 18 and 19, May 6 and 13, 1922, pp. 393–397 and 423–427, 29 figs. partly on supp. plate. May. 6: Describes civil-engineering features, damming of Fully Lake, pressure piping, etc. May 13: Electric generating machinery; turbine regulators; pipe lines.

I

INDICATORS

Indicator Diagrams of Compound Engine. Indicator Diagrams of Compound Engines. Power, vol. 56, no. 2, July 11, 1922, pp. 55–58, 10 figs. Classification of engine types; fixed and variable low-pressure cut-off. Other characteristics which determine proper setting of valves.

Micro, for High-Speed Engines. The Collins Micro-Indicator for High-Speed Engines. Engineering, vol. 113, no. 2945, June 9, 1922, p. 716, 3 figs. Description of instruments which within half a minute will produce on card ten successive indicator diagrams of performance of a high-speed engine.

INDUSTRIAL MANAGEMENT

Business Depression Cycle. Facts May Prevent Depressions, Ernest F. Dubrul. Iron Trade Rev., vol. 70, no. 25, June 22, 1922, pp. 1791–1794. Ignorance of business cycles brings reversals; burden rests upon management of modern industry to study basic factors; should contribute to general store by frank publicity about its own conditions.

Cost Explanation for Employees. Interpreting the Corporation to the Workers, C. M. Ripley. Elec. World, vol. 79, no. 25, June 24, 1922, pp. 1281–1282, 2 figs. Value of explaining distribution of costs to employees.

Manager's Problems. Solving the Manager's Present Day Problems, John H. Van Deventer. Indus. Management, vol. 64, no. 1, July 1922, pp. 1–3. Barriers to improved methods and how to overcome them.

Planning and Controlling, Chart for. Planning and Controlling Work in the Assembling Department of a French Shop, E. Jullien. Am. Mach., vol. 56, no. 25, June 22, 1922, pp. 932–933, 6 figs. Work plotted on revolving calendar and always under control of planning department; forms used for assembly specifications and piece-work tickets.

Psychosis of Industry. The "Psychosis" of Industry, Frank Mason Harris. Indus. Management, vol. 64, no. 1, July 1922, pp. 18–23. Application of psychoanalysis methods in relieving friction between employer and worker.

Purchase Controlled by Output Records. Making Output Records Control Material Purchases, Kenneth Coggeshall. Indus. Management, vol. 64, no. 1, July 1922, pp. 6–11, 23, 6 figs. Practical procedure for conservative purchasing with materials in stock bought at former high levels.

Shop-Record Keeping. Record Keeping on Dies, Tools and Scrap, Geo. H. Koskey. Forging & Heat Treating, vol. 8, no. 6, June 1922, pp. 279–282, 6 figs. Ideas as to data which can be kept and discussion of die bonus and die piecework.

INTERNAL-COMBUSTION ENGINES

Fuels. Research Aimed at Solution of Fuel Problem, Herbert Chase. Automotive Industries, vol. 46, no. 26, June 29, 1922, pp. 1412–1418, 5 figs. Cooperation of automotive and petroleum industries; new knock preventive announced by General Motors; lubricating problems also discussed.

The Value of Gas Engine Fuels, Letson Balliett. Min. Rev., vol. 24, no. 5, June 15, 1922, pp. 14–15. Exposition of impossible claims to increase heat values of hydrocarbon fuels; use of fuel oil in blacksmith's shop.

Combustion. Combustion Research—An Aid to Better Performance, Herbert Chase. Automotive Industries, vol. 46, no. 23, June 8, 1922, pp. 1253–1265, 2 figs. Internal-combustion engines; factors affecting detonation; flame propagation and related subjects examined by various investigators.

Reversing Turbine for Marine. The Starting and Reversing of Marine Internal-Combustion Engine with the Aid of Compressed-Air Turbines (Ueber das Anlassen und Umsteuern von Schiffs-Verbrennungskraftmaschinen mit Hilfe von Druckluftturbinen), Paul Praetorius. Schiffbau, vol. 23, nos. 28, 29, 30, 32, 34 and 35, Apr. 12, 19, 26, May 10, 24, and 31, 1922, pp. 851–857, 879–886, 911–915, 959–963, 1007–1012 and 1035–1040, 19 figs. Describes reversing turbine developed by author for a 60-hp. four-cylinder, four-cycle Diesel engine, points out its advantages and gives results of tests; comparison with other reversing systems.

Sproule. The Sproule Internal Combustion Engine. Oil Eng. & Finance, vol. 1, no. 81, March, 4 1922, pp. 277–279, 1 fig. Description of engine in which it is claimed that difficulties of limited flexibility, low efficiency, and lack of easy reversibility are almost completely overcome.

Still System for Marine. The Still System of Internal-Combustion Engine for Marine Purposes, F. Leigh Martineau. Steamship, vol. 33, no. 396, June 1922, pp. 414–416. Description of system which is applicable to several types of engines. Read before Inst. Mar. Engrs.

[See also AIRPLANE ENGINES, AUTOMOBILE ENGINES, DIESEL ENGINES, GAS ENGINES, OIL ENGINES.]

IRON

Metallography. Influence of Graphite on Iron, J. W. Bolton. Foundry, vol. 50, no. 11, June 1, 1922, pp. 436–443, 19 figs. Theories advanced for varying effects of graphite on cast iron and semi steel explain states in which it is found, causes are analyzed, micrographs illustrate points.

IRON INDUSTRY

Nord-Paris Co. Plant. The Works of the Nord-Paris Company. Engineering, vol. 113, no. 2945, June 9, 1922, pp. 708–709, 2 figs. Description of steel works, iron foundry, large machine shop, and auxiliary buildings covering some 50,000 sq. yd.

IRON ORE

Chromite. Chromite for the Manufacture of Ferro-Chrome, J. A. Holden. So. African Min. & Eng. Jl., vol. 33, no. 1595, Apr. 22, 1922, pp. 1120–1121, 1 fig. Rhodesian and new Calcedonian ores contrasted, varieties suitable for electrometallurgical smelting and some features of process.

Electric-Furnace Reduction. Electrothermic Reduction of Iron Ores and Pyrites (Sulla riduzione elettrotermica dei minerali di ferro e delle ceneri di pirite), Stefano Paghani. Forno Elettrico, vol. 3, no. 12, Dec. 15, 1921, pp. 168–183, 13 figs. Development of direct reduction of iron ore in electric furnace; summary description of the various furnaces and their working.

IRON, PIG

Silicon, Lower. Foundries Can Use Lower Silicon Irons, Y. A. Dyer. Iron Age, vol. 109, no. 25, June 22, 1922, pp. 1749–1750. Blast furnace-men would be relieved by lessened demand for high-silicon pig; call for high-phosphorus iron may be overdone also.

L

LEATHER

Drying Artificially. Artificial Drying of Leather, M. Hirsch. Eng. Progress, vol. 3, no. 6, June 1922, pp. 123–125, 5 figs. Arrangement for regulating admission of air according to progress of drying and proportioning recirculated and fresh air as drying proceeds.

LIGHTING

Industrial. Industrial Lighting: Ideal Requirements (Legislative and Otherwise) and Practical Solutions, L. Gaster. Illuminating Engr., vol. 15, no. 2, Mar. 1922, pp. 74–88, 8 figs. Consideration of four essentials for ideal lighting and discussion of code. Paper read before Illuminating Eng. Soc.

LIME

Plants. The New Rockland Lime Plant, Nathan C. Rockwood. Rock Products, vol. 25, no. 12, June 17, 1922, pp. 35–44, 36 figs. Six continuous-discharge, gas-fired mount design kilns of which five turn out 130 tons of lime in 24 hours.

A Plant Ahead of Its Time, Clinton S. Darling. Rock Products, vol. 25, no. 12, June 17, 1922, pp. 59–68, 32 figs. Rotary kiln for dry or semi-wet burning, with 175 ft. flame; remarkable flexibility to make every lime product at Am. Lime & Stone Co.'s plant.

LOCOMOTIVE BOILERS

Circulation, Effect on Efficiency. Effect of Circulation on Locomotive Boiler Efficiency, F. G. Lister. Ry. Rev., vol. 70, no. 22, June 3, 1922, pp. 787–790. Needed improvements in design for effecting better circulation, covered in paper presented at annual convention of Int. Ry. Fuel Assn. 1922.

LOCOMOTIVES

Fire Box, Water-Tube. Development of a Practical Water Tube Locomotive Fire Box, D. L. Kiss. Ry. Rev., vol. 70, no. 24, June 17, 1922, pp. 900–908, 16 figs. Hungarian state railways successfully operating locomotives equipped with Broton type boilers, use of water purifiers an important factor.

Design and Equipment. Current Questions of Locomotives Design and Equipment. Ry. Rev., vol. 70, no. 25, June 24, 1922, pp. 982–987, 1 fig. Am. Ry. Assn. Committee on locomotive construction considers relative merits of locomotive types and details in design. (Abstract.)

Fuel Economy. Effect of Tonnage Rating and Speed on Fuel Consumption, J. E. Davenport. Ry. Rev., vol. 70, no. 22, June 3, 1922, pp. 777–782, 10 figs. Practical interpretation of results of laboratory tests conducted in Pennsylvania Locomotive testing plant, showing heavy slow-speed trains to be most economical. Papers read before Int. Ry. Fuel Assn.

Locomotive Fuel—The Life Blood of Transportation, G. M. Basford. Ry. Rev., vol. 70, no. 22, June 3, 1922, pp. 742–785, 2 figs. Salient points in address at annual convention of Int. Ry. Fuel Assn.

Headlights, Electric. Effect of Design on Headlight Maintenance, R. Wayne Cargo. Ry. Age, vol. 73, no. 1, July 1, 1922, pp. 31–32, 4 figs. Cost of turbine-generator operation calls for careful consideration in selection of equipment.

Mallet for Pekin-Suiyuan. Heavy Mallet Locomotive for Pekin-Suiyuan. Ry. Mech. Engr., vol. 96, no. 6, June 1922, pp. 305–307, 5 figs. Largest locomotives exported or operated outside of U. S. now in service in China.

Mikado for Michigan Central. Lima Builds a New Mikado for the Michigan Central. Ry. Rev., vol. 70, no. 24, June 17, 1922, pp. 910–911. Locomotive 8000 recently placed in service weighs 334,000 lb. and exerts tractive effort of 63,500 lb. without booster.

Southern Pacific, 2-10-2. 2-10-2 Type Locomotive for the Southern Pacific. Railroad Herald, vol. 26, no. 7, June 1922, pp. 19–21, 2 figs. Description of locomotive of which 50 have recently been ordered.

Fifty More New Freight Locomotives for the Southern Pacific. Ry. Rev., vol. 70, no. 24, June 17, 1922, pp. 897–900, 5 figs. Southern Pacific motive power reflects evolution of 2-10-2 type, new locomotive equipped with Boosters and feedwater heaters.

Superheater. The New Locomotives of the Halberstadt-Blankenburg Railroad Company (Die neuen Lokomotiven der Halberstadt-Blankenburger Eisenbahn-Gesellschaft), Gustav Hammer. Glasers Annalen, vol. 90, no. 11, June 1, 1922, pp. 192–200, 10 figs. Describes new type 1E1 superheater locomotive with tender, built by Borsig, which shows reduction in fuel consumption and considerable increase in tractive effort.

The Superheater Locomotive—Its Lubrication. Lubrication, vol. 8, no. 5, May 1922, pp. 49–60, 10 figs. Important features in operation and lubrication in connection with these.

Uniflow. Recent Developments in the Unaflow Locomotive. Ry. Age, vol. 72, no. 25, June 24, 1922, pp. 1727–1730, 7 figs. Exhaust ejector effect overcomes handicap of high compression and reduces size of cylinders.

LUBRICATING OILS

Frictional Loss, Testing. A Practical Way to Test Lubricating Oils for Frictional Losses, W. F. Osburne. Power, vol. 55, no. 26, June 27, 1922, pp. 1010–1011. Readings to be taken; heat carried away from bearings; considerations other than bearing temperatures.

Storing and Handling. The Storage and Handling of Lubricating Oil, Allen F. Brewer. Indus. Management, vol. 64, no. 1, July 1922, pp. 27–30, 4 figs. Application of engineering principles to elimination of waste and obtaining maximum efficiency.

Voltol. The Production of Voltol. Eng. Progress, vol. 3, no. 6, June 1922, pp. 121–122, 2 figs. Process of making high-viscosity oil from thin cheap ones under effect of electrical glow discharges in rarefied gas.

LUBRICATION

Lubricants and. Lubrication and Lubricants, W. A. Ludwick. Steam, vol. 29, no. 6, June 1922, pp. 157–164. Consideration of straight-run mineral, blended mineral, compounded and animal oils; greases; selection of lubricants.

Petroleum. Petroleum and Lubrication, E. A. Evans. Oil Eng. & Finance, vol. 1, no. 13, Apr. 8, 1922, pp. 434–436. Consideration of true friction and proper specifications for oil to overcome same; constitution of film; carbonization; emulsion. Paper read before Inst. Mar. Engrs.

M

MACHINE GUNS

Hotchkiss Company, Levallois Works. The Levallois Works of the Hotchkiss Company. Engineering, vol. 113, no. 2945, June 9, 1922, pp. 710–711, 4 figs. Description of plant arranged for fine machine work.

MALLEABLE CASTINGS

Manufacture. Production of Malleable Castings and the Triplex Process (La fabrication de la Fonte malleable et le Procede Triplex), T. Levox. Fonderie Moderne, no. 6, June 1922, pp. 169–173. Composition and properties of malleables produced by triplex and other processes; electric production of malleable castings in continuous furnace.

MALLEABLE IRON

Manufacture. Malleable Anneals Not Packed, E. K. Smith. Foundry, vol. 50, no. 11, June 1, 1922, pp. 457–458, 2 figs. Pot with flange at both ends is developed to prevent gases from entering and attacking castings; temperature must be kept low to eliminate warping when castings are not supported.

Standardization. Standardizing Malleable Iron (Ueber die "Normung" von Temperguss), Rudolf Stotz. Giesserei-Zeitung, vol. 19, nos. 20 and 21, May 16 and 23, 1922, pp. 301–303 and 319–322, 3 figs. May 16: Dependence of tensile strength on thickness of wall and methods of production; gives figures for tensile strength from various foundries. May 23: Chemical composition and physical tests; shrinkage; etc.

MATERIALS

Testing Method. The Sliding Cone as Basis for Testing Materials (Die Rutschkegelbildung all Grundlage zc das Materialprüfwesen), Friedr. Riedels. Zeit. des Vereines deutscher Ingenieure, vol. 66, no. 23, June 10, 1922, pp. 566–571, 17 figs. Defects of present theory of stresses in materials; formulates new laws on basis of experiment, and discusses their application to testing of materials.

METALLOGRAPHY

Preparation of Metal. Preparation of Metal for Microscopic Examination, Wm. Campbell. Chem. & Met. Eng., vol. 26, no. 25, June 21, 1922, pp. 1163–1164. Preparation of specimens, development of structures for various samples.

METALS

Fatigue. Fatigue of Metals, C. E. Stromeyer. Iron & Coal Trades Rev., vol. 104, no. 2831, June 2, 1922, pp. 822–824, 2 figs. Empirical law by which fatigue limit may be obtained by direct measurement quickly and fatigue coefficient within one-half hour. (Abstract.) Paper read before So. Wales Inst. of Engrs.

Calorizing. Calorization (Note sur la calorisation), Léon Guillet. Bul. Technique du Bureau Veritas, vol. 4, no. 4, Apr. 1922, pp. 83–86, 3 figs. Discusses methods of protecting metallic articles, especially calorization or coating by means of aluminum by Schoop spraying process.

Casting. The Casting of Metals, Thomas Turner. Brass World, vol. 18, no. 6, June 1922, pp. 191–195. Consideration of melting and molding of metals as a whole with special attention to non ferrous alloys. Lecture before Inst. of Metals.

Cold Rolling and Drawing. The Process of Cold Rolling and Drawing and Its Consumption of Power (Der Kaltwalz- und Ziehvorgang und sein Leistungsverbrauch), L. Weiss. Zeit. für Metallkunde, vol. 14, no. 4, Apr. 1922, pp. 160–172, 18 figs. Develops formulas for calculating power required for cold rolling and applies results to wire drawing, giving examples.

Properties, Effect of Temperature on. The Effect of Temperature on Some of the Properties of Metals, F. C. Lea. Engineering, vol. 113, no. 2948, June 30, 1922, pp. 829–832, 11 figs. Results of experiments on critical points; tensile tests at from 40 deg. to 1000 deg. cent. tests on Armco iron; table showing properties of iron and certain steels at various temperatures; alloys of aluminum and copper. Paper read at Paris meeting of I.M.E.

METRIC SYSTEM

Arguments Against Adoption. Standardization and the Metric System (La standardizzazione e la serie metrica standard), Narciso Desirello. Industria, vol. 36, no. 9, May 15, 1922, pp. 163–167, 6 figs. Concludes that metric system, although perfect theoretically, is entirely inadequate for practical use and modern industrial exigencies.

MILLING MACHINES

Horizontal. A New Horizontal Milling Machine (Neue Wagerecht-Fräsmaschinen), M. Naumann. Ziet. des Vereines deutscher Ingenieure, vol. 66, no. 20, May 20, 1922, pp. 486–490, 33 figs. Describes new universal type built by Saxon Milling Machine Works, Chemnitz, and gives particulars of operation.

MINE LOCOMOTIVES

Germany. Mine Locomotive Conveying in the Ruhr District (Der Stand der Grubenlokomotivdörderung im Ruhrbezirk), O. Gunderloch. Glükauf, vol. 58, nos. 20, 21 and 22, May 20, 27 and June 3, 1922, pp. 589–592, 616–622, and 653–657, 25 figs. Describes various types of benzol, wired electric, electric accumulator, and compressed-air locomotives; their management and cost of operation.

MOLDS

Ingot, Production. Production of Molds for Steel Works (Ueber die Herstellung von Stahlwerkskokillen), A. Richold. Giesserei-Zeitung, vol. 19, no. 15, Apr. 11, 1922, pp. 239–241. Thickness of wall and relation to size of ingot.

MOTION PICTURES

Films. Chemical Production and Treatment of Films (Die chemische Herstellung und Behandlung von Filmen), S. Halen. Kunststoffe, vol. 12, no. 10, May 2, 1922, pp. 73–76. Discusses production from nitrocellulose, copper oxide, ammonia cellulose, viscose, cellulose hydrates in caustic alkali, etc., also sensitizing of gelatin layer.

MOTOR BUSES

Design. What Constitutes a Perfect Motor Bus? G. A. Green. Automotive Industries, vol. 46, no. 25, June 22, 1922, pp. 1364–1371, 14 figs. Controlling design factors are safety, comfort, and minimum operating cost. They can be obtained with low center of gravity, wide frame, track and spring centers and effective braking. Short turning radius is necessary, together with clear vision for driver. (Excerpt.) Paper read before Soc. Automotive Engrs.

Design and Operation. Motor Bus Design and Operation, G. A. Green. Bus Transportation, vol. 1, no. 7, July 1922, pp. 369–375, 13 figs. Construction of single-deck and double-deck vehicles; factors involved in minimum operating cost; maximum accessibility requires separate unit form of chasis construction. (Abstract.) Paper read before S.A.E.

MOTOR TRUCKS

Parts Inspection. Rigid Inspection One of Rules at this Plant. Can. Machy., vol. 27, no. 25, June 22, 1922, pp. 47–48, 2 figs. Practice at Nat. Steel Car Corp., Hamilton, Ont. Parts purchased from outside sources are tested before leaving place of manufacture; further test given at Hamilton factory; jigs and fixtures are extensively used.

N

NICKEL ALLOYS

Chromel. Chromel Castings, Bars, Wire and Ribbons, E. F. Lake. Brass World, vol. 18, nos. 5 and 6, May and June 1922, pp. 158–161 and 165–167, 9 figs. Nickel-chromium alloy with higher chromium content than is found in others; its uses.

Nickel-Chromium Casting. Cast Nickel-Chromium Alloys, E. F. Lake. Foundry, vol. 50, no. 11, June 1, 1922, pp. 452–454, 6 figs. Metals are melted

in induction, arc and crucible-type electric furnaces; purity found to be essential, iron added to one of alloys; occluded gases a menace in melting.

O

OIL ENGINES

Cold-Starting Crude. The Brotherhood Cold-Starting Crude Oil Engine. Engineering, vol. 113, no. 2946, June 16, 1922, pp. 746–748, 12 figs. Horizontal 4-cycle type started by compressed air on regular fuel. Will operate after starting on any grease that can be pumped.

OIL FUEL

Burning Efficiency. How to Burn Fuel Oil Efficiently, Jos. W. Hays. Refrigeration, vol. 30, no. 2, Apr. 1922, pp. 31–36. Correct conditions of furnace, atomizing burner, air supply and operation.

OIL INDUSTRY

California. Oil Industry in California, Henry M. Payne. Eng. & Min. Jl.-Press, vol. 113, no. 25, June 24, 1922, pp. 1099–1103, 3 figs. Extensive records by state of operations; "peg models;" standard methods employed.

Records, Forms for Keeping. Forms for Keeping Records. Oil Field Eng., vol. 24, no. 5, May 1922, pp. 130–136. Suggestions for preparation of sheets on which to keep records, and summary of information that should be collected

OIL SHALES

Esthonian. The Chemical Properties of Esthonian Shales. Petroleum Times, vol. 7, no. 178, June 3, 1922, pp. 777–778. Some facts about most successful development in this field and unusually rich properties of shale.

Kukkersite, the Oil Shale of Esthonia, F. H. Cunningham. Petroleum World, vol. 19, no. 261, June 1922, pp. 255–259. Facts about occurrence and development of one of richest oil shales known.

OPEN-HEARTH FURNACES

British Practice. British Open-Hearth Furnace Practice. Iron Age, vol. 110, no. 2, July 13, 1922, pp. 75–78, 2 figs. Higher temperatures and more rapid working aimed at in proposed design of a 100-ton furnace; reduction of heat losses great desideratum.

Design Improving. Improving Open-Hearth Design, Willis McKee. Iron Trade Rev., vol. 70, no. 26, June 29, 1922, pp. 1865–1868, 5 figs. Blow-torch principle insures better combustion; proposal to introduce gas into uptakes without regeneration; improved design is resulting in greatly increased output, better steel and longer life of furnace.

Valves. Gas and Air Valves for Open Hearth Furnaces, Wm. C. Bulmer. Blast Furnace & Steel Plant, vol. 10, no. 6, June 1, 1922, pp. 302–306, 4 figs. Discussion of development of various types of valves for which each inventor claims some superiority.

ORDNANCE PLANTS

U. S. Navy. Naval Gun Factory at Washington, Sidney G. Koon. Iron Age, vol. 110, no. 2, July 13, 1922, pp. 87–90, 3 figs. Exceptionally massive machine tools for production of heaviest naval ordnance; subsidiary work of great importance.

OVENS

Electric, Enameling. Electric Ovens Are A Good Investment, West S. Scott. Elec. Rev. & Indus. Engr., vol. 80, no. 6, June 1922, pp. 275–277, 4 figs. Flexibility and ease of heat control, freedom from gases and low maintenance are among advantages of various examples discussed.

OXY-ACETYLENE CUTTING

Cutting Machines. Oxy-Acetylene Cutting Machine, I. William Chubb. Am. Mach., vol. 56, no. 25, June 22, 1922, pp. 929–931, 5 figs. Mechanically guided torch cuts intricate shapes at great speed; gas pressure and rate of torch travel regulated to suit work.

Machine, Efficiency of. Efficiency of Machine Cutting, Fred J. Maeurer. Acetylene Jl., vol. 23, no. 12, June 1922, pp. 587–595, 25 figs. Cutting with oxy-acetylene torch can be made to approach very closely maximum theoretical efficiency. Paper read before Am. Welding Soc

Underwater. The Underwater Torch Makes Good. Pacific Mar. Rev., vol 19, no. 6, June 1922, pp. 337–339, 5 figs. Temperature of 6000 deg. fahr. enables diver to cut metals at any depth to which he can descend.

OXY-ACETYLENE WELDING

Foundries. Oxy-Acetylene Cutting and Welding in Foundry, G. O Carter. Can Foundryman, vol. 13, no 6, June 1922, pp. 36–39. Piped oxygen and acetylene installations are recommended for large foundries Many uses, such as cutting steel risers and welding gray iron.

P

PAINTS

Exposure Tests. Miscellaneous Exposure Tests, Henry A. Gardner. Educational Bur., Paint Manufacturers' Assn of U. S, no. 153, June 1922, pp 282–313, 12 figs. Durability tests on paints applied by spray gun vs. hand brush; three-year exposure results on Atlantic City panels; and tests on metal power paint, titanium oxide pigment and antimony oxide pigment.

PAPER MANUFACTURE

New Paper From Old. Making New Paper From Old Paper Stock, Sidney D Wells. Paper, vol. 30, no. 14, June 7, 1922, pp. 7–10. Deinking processes for old newspapers and use of bentonite as peptizing agent.

PAPER MILLS

Machines, High-speed. Developments in High Speed Machines. Paper, vol. 30, no. 12, May 24, 1922, pp. 7–11. Effect of late developments in making paper by high-speed processes.

PIPE, CAST-IRON

Centrifugal Process. Cast Iron Water Pipe Made by de Lavaud Process. Can. Foundryman, vol. 13, no. 5, May 1922, pp. 26–27, 33, 2 figs. Melted metal poured into revolving mold is deposited by centrifugal force against wall of mold; makes dense grained homogeneous casting.

Failure, Causes of. Causes of Failure in Cast Iron Pipe, F. A. McInnes. Eng. & Contracting, vol. 62, no. 24, June 14, 1922, pp. 563–564. Quality of pipe line; permissable sulphur content; importance of analyses of iron.

PIPES

Coating for Cast Iron and Steel. The Right Kind of Coating for Pipe, Wm. R. Conard. Fire & Water Eng., vol. 71, no. 25, June 21, 1922, pp. 1107–1108 and 1122, 1 fig. Suggestions for durable and efficient coating that will insure longer life for cast-iron or steel pipe. From paper read before Convention of Am. Water Wks. Assn.

Tar Coating for. Present Day Tars for Pipe Coatings, Wm. R. Conard. Can. Engr., vol. 42, no. 22, May 30, 1922, pp. 560–561. Dr. Angus Smith's solution; standard specification for pipe coatings; quality of tar used at present time; objective for research work. Paper read at Annual Mtg. Am. Water Wks. Assn.

PISTON RINGS

Quantity Production. Quantity Production of High-Grade Piston Rings (Massenerzeugung höchstwertiger Kolbenringe), C. Irresberger. Stahl u. Eisen, vol. 42, no. 22, June 1, 1922, pp. 841–845, 12 figs. Demands made on piston rings; sand and permanent molds for casting; centrifugal casting process; etc.

PISTONS

Aluminum. Aluminum Pistons (A propos des Pistons en aluminium), Frank Jardine and Ferdinand Jehle. Technique Automobile et Aérienne, vol. 13, no. 117, 1922, pp. 54–59, 9 figs. Design and operation; measurment of temperature, tolerance, etc.

PLANERS

Foundations. Second-Story Planer Foundations, A. E. Robinson. Am. Mach., vol. 56, no. 25, June 22, 1922, pp. 917–919, 4 figs. How American Tool Works supports its planer department upstairs; concrete slabs for foundations; methods of leveling and straightening long planer beds.

PLATES

Rectangular, Stress in. Method for Approximate Static Calculation of the Bending Stress of Rectangular Plates (Verfahren zur angenäherten statischen Berechnung biegefester rechteckiger Platten), Ludwig Hotopp. Beton u. Eisen, vol. 21, nos. 6 and 8, Apr. 5 and May 9, 1922, pp. 95–97 and 116–119, 8 figs. Discusses distribution of stresses and gives examples and calculations.

POWER PLANTS

Chile. The Power Works of Chuquicamata (Los talleres y fuerza motriz de Chuquicamata). Ingenieria Internacional, vol. 8, no. 2, Aug. 1922, pp. 89–94, 3 figs. Production of power for mines and metallurgical works; a central heating station which burns oil and uses salt water.

Management. Power Station Management. J. S. Thomson. Iron & Coal Trades Rev., vol. 104, no. 832, June 9, 1922, pp 817–818. Sixteen economic areas suggested for England, most of power must come from thermal efficiency; gas and electric typical stations; automatic operations; steam considerations; electrical details.

Paper Mills. The Provincial Paper Mills, Power Plant, T. H. Fenner. Power House, vol. 15, no. 11, June 5, 1922, pp. 19–23, 8 figs. Interesting features of boiler room and facilities for enlargement of plant.

Wheeling Steel Corporation. Wheeling Steel Corporation Construct New Power Plant, Thos. G. Estep. Blast Furnace & Steel Plant, vol. 10, no. 6, June 1, 1922, pp. 329–337, 11 figs. Detailed description of modern power station constructed at Whitaker-Glessner plant, Wheeling, W. Va.; many unusual features mark plant.

PRESSES

Power, Crankshaft Design. Designing Power Press Crankshafts, Wm. J. Smith. Eng. Production, vol. 4, no 87, June 1, 1922, pp. 509–513, 5 figs. Details of calculations and formulas involved.

PULVERIZED COAL

Boiler Firing. Progress in Pulverized Fuel Firing, F. J. Crolius. Blast Furnace & Steel Plant, vol. 10, no 6, June 1, 1922, pp. 337–339. Code recommended for adoption by Carnegie Steel Company in handling of pulverized coal, presented; many points of unnecessary danger have been eliminated.

Danger of Explosion in Pulverized Coal Firing, (Die Explosionsgefahr bei Kohlenstaubfeuerungen), Mathtiass. Technische Blatter, vol. 12, no. 22, June 3, 1922, pp. 225–227. Direct and indirect methods of firing; safety regulations to avoid explosions.

Powdered Fuel under Steam Boilers. Iron & Coal Trades Rev., vol. 104, no. 2, 832, June 9, 1922, p. 858. Summary of results of five boiler tests with pulverized Illinois coal, made by Milwaukee Elec. Ry. & Light Co.

Combustion. Dangers of Coal Dust (Die Gefahren des Brennstaubes), A. B. Helbig. Feuerungstechnik, vol. 10, no. 17, June 1, 1922, pp. 188–190. Discusses in detail process of combustion and shows that with ordinary care there is no danger of explosion.

Fire Hazards. Fire Hazards in Plants Using Pulverized Coal, L. D. Tracy. Blast Furnace & Steel Plant, vol. 10, no. 7, July 1922, pp. 395–399. Various cases where fires and explosions originated from improper handling of pulverized coal; many hazards connected to apparatus used for pulverizing.

Stationary Boilers. Use and Abuse of Powdered Fuel for Stationary Boilers, John E. Muhlfeld. Blast Furnace & Steel Plant, vol. 10, no. 6, June 1922, pp. 353–355. Any great advance in combined boiler and furnace efficiency will depend largely upon full utilization of radiant heat.

PUMPING PLANTS

Land Drainage. Pumping Plants for Land Drainage, L. C. Craig. Can. Engr., vol. 42, no. 21, May 23, 1922, pp. 525–527. Reclaiming land in Mississippi River valley; electrically driven centrifugal pumps often used for drainage work; advantage of Diesel engines.

PUMPS

Endless-Chain. The "Aquatole" Endless-Chain Pump. Engineering, vol. 113, no. 2948, June 30, 1922, pp 827–828, 9 figs. Installation of Aquatole liquid lifter which has capacity of 20,000 gal. per hr. with driving pully speed of 350 r.p.m.; efficiency of 55 per cent is attainable and ease of setting up and variety of liquid that can be handled are desirable features.

Gasoline, for Aircraft. The "Sylphon" Petrol Pump. Flight, vol. 14, no. 24, June 15, 1922, p. 344, 2 figs, Eliminates troubles arising from glands and their packing, and gives maximum discharge pressure at high speeds and sufficient delivery of fuel at any speed.

Hydrautomat. The Hydrautomat. Elec. Times, vol. 61, no. 1600, June 15, 1922, pp. 573–574, 2 figs. Invention whereby water is lifted through open and closed tanks by small water stream.

Valveless Reciprocating. A Valveless Reciprocating Pump. Colliery Guardian, vol. 123, no. 3206, June 9, 1922, pp. 1420–1421, 4 figs. New type which effects operation of opening and closing inlet and outlet ports by means of alternate axially reciprocating and rotary-oscillating movements of piston or cylinder itself.

PUMPS, CENTRIFUGAL

Efficiency. Centrifugal Pumps—Notes on Efficiency, E. T. Keenan. Southern Engr., vol. 37, no. 4, June 1922, pp. 39–40, 2 figs. Factors bearing on efficiency of turbine and volute pumps.

Electrically Driven. Centrifugal Pumps and Pipe Lines (Om Centrifugalpumper og Rörledninger), Rich. Holm. Ingeniören, vol. 31, no. 29, May 20, 1922, pp. 181–185, 10 figs. Discusses electrically driven pumps, power required, effective working, friction, etc.

Submersible Motor. Submersible Motors. Practical Engr., vol. 65, no. 1842, June 15, 1922, pp. 371–372, 2 figs. Extreme portability, lightness and compactness; suction lift of 30 ft.; when pump is working submerged no suction hose or priming is required; advantages of this device.

R

RADIATORS

Casting Parts. Carting of Radiator and Boiler Parts (Fortschritte in der Radiatoren- und Gliederkessel-Giesserei), Carl Irresberger. Giesserie-Zeitung, vol. 19, nos. 12 and 13, Mar. 21 and 28, 1922, pp. 185–189 and 204–205, 14 figs. Mar. 21: Operations connected with casting of radiators. Mar. 28: Patterns, forms and casting of boiler parts.

RAILWAY CONSTRUCTION

Leipzig, Germany. The Rearrangement of the Leipzig Railway Facilities (Die Umgestaltung der Leipziger Bahnanlagen durch die Preussische und Sächsische Staatseisenbahnverwaltung), H. Rothe, H. Mirus, H. Christoph, H. Schmitz and H. Schlunk. Zeit. für Bauwesen, vol. 71, nos. 4–6, 7–9, 1921, pp 168–198, 259–299 and vol. 72, nos. 1–3 and 4–6, 1922, pp. 37–76 and 131–156, 267 figs. partly on supp. plates. General notes on plan of entire railway installation in and around Leipzig; union passenger and freight stations, including description of plan of lines; interlocking machines; light and power supply, water supply and drainage installations; passage of city streets through terminal zone, including laying of new street and construction of iron viaduct.

RAILWAY ELECTRIFICATION

Austria. The Work of Electrification of the Austrian State Railways at the Beginning of 1922 (Der Stand der Arbeiten in die Elektrisierung der österreichischen Bundesbahnen zu Beginn des Jahres 1922), Paul Dittes. Elektrotechnik u. Maschinenbau, Special Number June 1922, pp. 1–34, 57 figs. Canal construction work in progress at Lake Spüller; extension of Rutz works; turbine equipment and electric

installation of both works; details of transmission masts and transmission lines, current feeds of locomotives; etc. See also Zeit des Österr Ingenieur-u. Architekten-Vereines, vol 74, no. 23 24, June 9, 1922, pp. 99–106, 4 figs.

Chilean State Railways. Electrification of the Chilean State Railways. Engineer, vol 133, no. 3470, June 30, 1922, pp 711 714, 11 figs Utilization of great water power resources for reducing working expenses, increasing traffic capacity and obviating dependence on coal supply from other countries; technical features of problem.

English Main Line. The Electrification of English Main Line Railways, Henry Fowler Instn Mech Engrs. Proc., no. 3, 1922, pp. 317 330 Discussion of paper presented at joint meeting of Instn Mech. Engrs., Instn. Civil Engrs., and Instn Elec Engrs

Japan. Electrification of the Chichibu Railway of Japan, C. A. Bereaw. Ry Rev., vol 70, no 24, June 17, 1922, pp 911 912, 2 figs. Five 41 ton locomotives shipped by Westinghouse Co., represent first shipment of electric locomotives from America for operation on steam railroad electrification in Japan.

Switzerland. Conclusion of the Work of Electrification of Rhaetian Railway (Der Abschluss der Elektrifizierungsarbeiten der Rhätischen Bahn) W. Dürler Schweizerische Bauzeitung, vol. 79, nos. 14, 15, 20, 21 and 22, Apr 8, 15, May 20, 27 and June 3, 1922, pp. 180–183, 194 198, 249–254, 267–269 and 279–281, 26 figs. Apr 8 and 15: Discusses power plants at Thusis and Küblis, and their equipment, transmission lines, distributing system, transformers, etc May 20: Describes the various types of electric locomotive and gives particulars as to their wiring and connecting. May 27: Data of trial runs of locomotives, and heating of trains. June 3 Discusses workshops and enginehouses and their equipment

RAILWAY MOTOR CARS

Advantages of. What is the Future for Automotive Rail Cars? L. G. Plant Ry. Rev., vol 70, no. 24, June 17, 1922, pp 930–934, 3 figs. Modern features which are recommended for light local passenger service. From paper read before Soc. Automotive Engrs.

Diesel-Electric. Diesel-Electric Motor Cars for Railway Service. Ry Mech. Engr., vol. 96, no. 6, June 1922, pp 314–315, 2 figs. Successful operation in Sweden has led to introduction of 250-hp cars

Gasoline. Some Recent Developments in Gasoline Passenger Rail Cars, W. L. Bean. N. Y. R. R. Club Proc., vol. 32, no. 7, May 19, 1922, pp. 6713–6726 and (discussion) 6726–6744, 6 figs. Considerations which may assist in reducing charges by substituting for light steam trains.

Developments in Gasoline Passenger Rail Cars, W. L. Bean. Ry. Age, vol. 73, no. 1, July 1, 1922, pp. 17–20 (includes discussion), 3 figs. Design, power requirements and operating results of self-propelled cars. (Abstract.) Paper read before N. Y. R. R. Club.

120 Hp. Gasoline Motor Features New Rail Car Design. Ry. Rev., vol. 70, no. 24, June 17, 1922, pp. 934–937, 8 figs. Low maintenance and adaptability to wide range of rail requirements objective in latest automotive development.

New Features. New Features in Service Railway Motor Coach. Ry. Mech. Engr., vol. 96, no. 6, June 1922, pp. 337–338, 3 figs. Unique type of truck with cushioned wheels; high seating capacity combined with light weight.

Pittsburgh and Shawmut. Operation of Motor Cars on the Pittsburgh & Shawmut, D. C. Morgan. Ry. Rev., vol. 70, no. 24, June 17, 1922, pp. 928–929, 3 figs. Costs less to operate than local steam train; affords better and more frequent service. Paper read before N. Y. R. R. Club.

RAILWAY OPERATION

Train Control. Schweyer Automatic Train Control. Ry Elec. Engr., vol. 13, no. 6, June 1922, pp. 187–189, 3 figs. Intermittent, non-contact, inert roadside element type.

The Sprague Train Control System. Ry. Signal Engr., vol. 15, no 6, June 1922, pp. 226–230, 9 figs. Description of display system of auxiliary control by magnets.

RAILWAY REPAIR SHOPS

Albuquerque, N. M. A. T. & S. F. Ry. Shop Improvements at Albuquerque. Ry. Rev., vol. 70, no. 24, June 17, 1922, pp 889–896, 16 figs. Engineering and mechanical features of improvement program of largest locomotive erecting shop in West, involving expenditure of about $10,000,000.

Car Equipment Scheduling. Scheduling of Car Equipment Through Repair Shops. Ry. Rev., vol. 70, no 25, June 24, 1922, pp. 965–970, 6 figs. Am. Ry. Assn. Committee urges scheduling of heavy freight and passenger car repairs on same principle as recommended for locomotive repairs in 1922 report.

Glass Walls in. Santa Fe Ry. Has Large Steel-Frame Shop with Glass Walls. Eng News-Rec., vol. 89, no. 1, July 6, 1922, pp. 12–15, 9 figs. Glazing outside structural framing; T-columns carry 250-ton crane, folding rack doors; repair pits and floor track construction.

Grinding Practice. Railway Shop Grinding Practice in England. Ry. Mech. Engr., vol. 96, no. 6, June 1922, pp. 325–327, 3 figs. Interesting machines developed for grinding locomotive cylinders, car journals and mounted crank-pins.

Locomotive. Modern Management of Locomotive Boiler Repair (Neuzeitliche Betriebsführung in der Lokomotivkessel-Ausbesserung). Glasers Annalen, vol. 90, nos. 10 and 11, May 15 and June 1, 1922, pp. 169 181 and 200–205 and (discussion) 205 207, 36 figs. May 15: Management of staybolts and rivets, and operations connected with them. June 1: Record keeping of boiler repairs, and their management.

Passenger-Car. The Design of Passenger Car Repair Shops. Ry. Mech. Engr., vol. 96, no. 6, June 1922, pp. 332–336, 1 fig. Requirements for various departments outlined and typical layouts proposed by A.R.E.A. Committee.

Power Plants. Some Factors in the Design of Railway Power Plants. Ry. Rev., vol. 70, no 25, June 24, 1922, pp. 991–995, 5 figs Am. Ry. Assn. Committee on modernization of stationary boiler plants advocates welding pipe lines and reports on relative merits of steam turbines and uniflow engines. (Abstract.)

RAILWAY SIGNALING

Automatic. New Signaling on the Big Four, C. F. Stoltz. Ry. Signal Engr., vol. 15, no. 6, June 1922, pp. 221–224, 6 figs. A. C. floating battery installed for operation of 68 miles of double track automatics shows economy in operation.

Automatic Block. Automatic Block System in Operation at the Grande Ceinture (Block-System automatique en service sur la Grande Ceinture), Bernard. Révue Générale des Chemins de Fer et des Tramways, vol. 41, no. 6, June 1922, pp. 457–467, 10 figs. Describes Lartigue signaling system in use in Paris, its construction and operation, which so far has worked satisfactorily.

Operation, Economy in. Introducing Economies in Signal Operation, Sidney L. Baxter. Ry. Signal Engr., vol. 15, no. 6, June 1922, pp. 231–232, 4 figs. Storage batteries replaced by primary battery, electric lights installed, and maintenance force reduced.

Wires and Cables. Railroad Signal Wires and Cables, Wm. A. Del Mar and F. A. Westbrook. Ry. Signal Engr., vol. 15, no. 6, June 1922, pp. 233–239, 15 figs. Methods of installation and causes of deterioration of rubber insulated conductors.

RAILWAY STATIONS

Waterloo, England. The New Waterloo Station, London & South Western Railway. Ry. Gaz., vol. 36, no. 23, June 9, 1922, pp. 919–936, 25 figs. Description of rebuilding of largest station in British Isles and facilities provided.

RAILWAY TERMINALS

Mississippi River-and-Rail. New River-and-Rail Terminals on the Mississippi. Eng. News-Rec., vol. 89, no. 1, July 6, 1922, pp. 18–20, 3 figs. Truck conveyor bridge and car incline with cradle provide for varying river level; two concrete docks with cranes.

Detroit. Pennsylvania to Complete Entrance into Detroit. Ry. Age, vol. 72, no. 25, June 24, 1922, pp. 1717–1718, 1 fig. Project includes local freight terminal, classification yard and 25 miles of new line.

RAILWAY TRACK

Elevation. Aurora Track Elevation Expedites Traffic. Ry. Age, vol. 73, no. 1, July 1, 1922, pp. 7–11, 8 figs. Burlington's grade separation project is supplemented by plan for increasing facilities.

RAILWAY YARDS

Freight. New Haven Builds Freight Yards at Providence. Ry. Age, vol. 72, no. 24, June 17, 1922, pp. 1467–1470, 4 figs. New terminal forms important unit in broad improvement program to effect operating economies.

REFRIGERATING MACHINES

Condensers, Free-Air. Influencing the Pressure of Free-Air Condensers, M. Hirsch. Ice & Refrigeration, vol. 62, no. 6, June 1922, pp. 457–459, 4 figs. Descriptive article with charts on subject; formula for measuring difference of vapor tension between water surface and moisture contained in surrounding atmosphere; empirical curves for regulation of water and air.

REFRIGERATING PLANTS

Ice-Cream. Modern Ice-Cream Plant, Frank D. Chase. Ice & Refrigeration, vol. 62, no. 6, June 1922, pp. 454–456, 5 figs. Diagrams and description of modern ice-cream plant; factors to be considered; taking advantage of law of gravity; anticipation of provision for future; sanitation; ventilation and welfare requirements.

Overhauling. Overhauling the Refrigerating Plant, J. J. Grover. Southern Engr., vol. 37, no. 4, June 1922, pp. 46–49, 4 figs. Pointers regarding what to do when getting ready for season's run.

REFRIGERATION

Absorption Process. Refrigeration for the Power Plant Engineer. Power House, vol. 15, no. 12, June 20, 1922, pp. 31–32, 34, 2 figs. Absorption process of refrigerating; aqua ammonia; general construction and details of parts of machine; few words on operating features.

Absorption System. Outline of the Absorption Refrigerating System, D. L. Fagnan. Power, vol. 55, no. 25, June 20, 1922, pp. 977–979, 2 figs. Discussion of functions of several parts; cycle of events in system; operating procedure to be followed.

RELATIVITY

Theory. Criticism of the Theories of Relativity (Critiques des théories de la rélativité), P. Juppont. Génie Civil, vol. 80, nos. 19, 20 and 21, May 13, 20 and 27, 1922, pp. 430–431, 443–446 and 468–473, 2 figs. May 13: Discusses relativity and postulates, force, action and reaction, temperature, entropy. May 20: Relativists' solutions of these problems; inadequacy of relativity; Lorentz contractions. May 27: Shows that Einstein's theory is not a physical theory Physical mechanics, mechanical force and power.

RESEARCH

Malleable Iron. Malleable Castings Research Laboratory Iron Age, vol 109, no 26, June 29, 1922, pp. 1819 1820, 2 figs. Freedom from routine tests permits concentration on work to advance state of art.

ROLLING MILLS

Efficiency. Effective Work of the Rolling Mill (Die Nutzarbeit des Walzvorgangs), G. Liss. Stahl u. Eisen, vol. 42, nos. 18, 19, 20, 21 and 23, May 4, 11, 18, 25 and June 8, 1922, pp. 689 697, 735 741, 768 772, 806 816 and 891 896, 21 figs. May 4 and 11: Discusses deformation generally; velocity of changing forms per second per unit of volume in various rolling processes; power factor depending on temperature and velocity; etc. May 18: The external mechanical process during rolling, spreading and elongation, shaping, pressure and friction of rolls. May 25: Discusses resistance to deformation as dependent upon block temperature. June 8: Effect of velocity of changing form; determination and comparison of effective work.

Electrically Driven. Steel Rolled for Less on Electric Mills than with Steam Drive, G. E. Stoltz. Elec. World, vol. 80, no. 1, July 1, 1922, pp. 7–10, 2 figs. Records show that steam mills can often be replaced by electric mills with marked advantages; accurate cost accounting is possible with electric mills, and labor and maintenance costs are reduced.

Ship-Plate. The Dominion Iron and Steel Company's New Ship-Plate Rolling Mill, H. E. Rice. Can. Min. Inst. Trans., vol. 23, 1920, pp. 167–178, 5 figs. Description of $5,000,000-installation with its Lauth type 110-in. by 36-in three-high plate mill driven by 4,000-hp. 82 r.p.m. special motor.

S

SAFETY

Electric Power Stations. Safety as Applied to Operating Equipment of Large Electric Power Station, E. W. Gorry. Safety Eng., vol. 43, no. 6, June 1922, pp. 261–268. Provisions at plants and sub-stations of United Elec. Light & Power Co. and new Edison Company. Paper read before A.S.S.E.

Safety is Built into the Design of the New Hell Gate Electric Power Station, E. M. Van Norden. Safety Eng., vol. 43, no. 6, June 1922, pp. 257–260. Precautions resulting from knowledge of conditions existing at other stations where trouble has been experienced. Paper read before A.S.S.E.

SAND BLAST

Apparatus. Development of Sand Blast Apparatus in Germany and America (Die Entwicklung des Sandstrahlgebläsebaues in Deutschland und Amerika), W. Kaempfer. Giesserei-Zeitung, vol. 19, no. 19, May 9, 1922, pp. 289–292, 15 figs. Discusses the various types of apparatus and their operation.

SAND, MOLDING

Properties for Steel. Study Properties of Steel Sand. Iron Trade Rev., vol. 71, no. 2, July 13, 1922, pp. 103–106, 8 figs. Facing mixtures must possess highly refractory qualities to resist intense heat of steel at pouring temperatures; determining standards for measuring permeability and strength.

SCRAP

Railway, Reclamation of. Scrap Reclamation on the Chesapeake and Ohio, E. A. Murray. Ry. Mech. Engr., vol. 96, no. 6, June 1922, pp. 308–311, 8 figs. Methods used and savings effected in reclaiming locomotive, car and other parts at Huntington shops.

SEPARATORS

Magnetic. New Magnetic Separator for Low Magnetic Ores (Neue Magnetscheider für schwachmagnetische Erze), H. Bernhardt. Technische Blätte vol. 12, no. 10, Mar. 11, 1922, pp. 105–106, 4 figs, Discusses drum separators for large and small size of grain, and describes their operation.

SHIP PROPULSION, ELECTRIC

Machinery on SS San Benito. The Electric Propelling Machinery of the "San Benito." Engineering, vol. 113, no. 2946, June 16, 1922, pp. 749–752, 13 figs. Developing 2,500 s.hp. with propeller speed of 100 r.p.m. Turbo-alternator rated at 2,040 kw. at 3000 r.p.m. has 9-stage turbine operating on 190 lb. steam with 200 deg. fahr. superheat.

SHIPS

Conversion to Oil-Burning. Cunarder "Berengaria" Converted to Oil-Fuel Burning. Mar. Engr. & Naval Architect, vol. 45, no. 537, June 1922, pp. 236–240, 18 figs. Work of conversion by W. G. Armstrong, Whitworth & Co. Ltd., Walker-on-Tyne; White low-pressure oil-burning system by White Patent Oil Fuel Co.; largest boiler repair contract ever carried out on Tyne; general reconditioning and overhaul.

Gyrostabilizer. The Latest Sperry Gyro-Stabilizer Installation. Mar. Engr. & Naval Architect, vol. 45, no. 537, June 1922, pp. 218 219, 2 figs. New 120-ton stabilizer to be installed on American passenger liner "Hawkeye State;" general principles; some particulars of rolling experiments recently carried out on Italian destroyer.

SHOVELS

Rotary. The Clere Mechanical Rotary Shovel (Pelle mécanique rotative, système Clere), E. Weiss.

Génie Civil vol 80, no 21, May 27, 1922, pp. 477–479, 8 figs Describes Clere system for mechanical excavating loading, etc

SPRINGS

Accidents to, Securing Against. Securing Springs Against Accident Autocar, vol 48, no. 1389, June 3, 1922 pp 939–940, 2 figs. Description of some of devices employed to prevent fractured spring leaf from entirely deranging steering.

Laminated, for Automobiles. Laminated Springs for Automobiles, T H Sanders. Machy. (Lond.), vol. 20, nos 501, 503, 505, 507 and 508, May 4, 18 June 1 15 and 22, 1922, pp 125–128, 185–188, 249–253 317–321 and 345–348, 28 figs. Discussion of design of modern manufacturing appliances and processes and effect of standardization on production.

STEAM

Consumption. Steam and Steam Consumption (Wasserdampf und Dampfverbrauch), A. Hinz, Gluckauf, vol. 58, no 24, Jone 17, 1922, pp. 705–739, 18 figs. partly on supp. plate. Discusses structure of i-diagram (heat content and entropy) for steam, and Mollier table, and shows possibility of their application in number of examples for determination of theoretical consumption of steam per unit of performance.

Production and Use. Economies in Steam-Raising, T W. Harper. Gas Jl., vol. 158, no 3075, Apr. 19, 1922, pp. 154–156. Lancashire versus water-tube boilers; boiler settings and flues; feedwater and scale; fuel and grate; waste-heat utilization; superheaters; steam distribution. Paper read before North British Assn Gas Managers.

Production and Utilization. Commission for the Utilization of Fuels—5th Report (Commission d'Utilization du Combustible—Cinquième Rapport), V Krammerer. Annales des Mines, vol. 1, no. 5, May 1922, pp. 348–391. Production and utilization of steam; transportation of steam; steam power and pressure; application of steam in industries.

Work of the Fuel Utilization Commission, V. Kammerer (Travaux de la Commission d'Utilisation du Combustible) Bul. de la Société d'Encouragement pour l'Industrie Nationale, vol. 134, no 1, Jan 1922, pp. 50–78 Report on production and utilization of steam, including transmission, motive power, use of steam for manufacturing and heating purposes, etc. See also Chaleur et Industrie, no 24, Apr. 1922, pp. 1175–1182.

Supersaturated Condition. The Supersaturated Condition as Shown by Nozzle Flow, Prof. A. L. Mellanby. Engineering, vol. 113, no. 2948, June 30, 1922, pp. 832–835, 11 figs. Investigation of flow quantities exceeding those calculated on assumption of isentropic expansion of saturated steam. Paper read before Inst. Mech. Engrs.

STEAM ACCUMULATORS

Ruths. The Ruths Steam Accumulator on the Basis of the Patents of the Vaporackumulator Company in Stockholm (Der Ruths-Dampfspeicher auf Grund der Patente der Aktiebolaget Vaporackumulator in Stockholm). Kali, vol. 16, no. 12, June 15, 1922, pp. 234–238, 1 fig. Advantages of principle of steam accumulation for regulation of steam pressure; claims as stated in 17 German patents.

STEAM ENGINES

Uniflow. The Uniflow Steam Engine Industry. Power, vol. 55, no. 25, June 20, 1922, pp. 960–964, 8 figs Characteristics of this high-efficiency type which is thought to have kept steam-engine development from stagnation.

Uniflow Lubrication. Lubricating the Uniflow Engine Practical Engr., vol. 65, no. 1811, June 8, 1922 pp. 363–364. Errors in common practice indicated relieving excessive compression; selection of oil, speed and friction.

STEAM POWER PLANTS

Amsterdam. New Steam Plant at Amsterdam. Power Plant Eng., vol. 26, no 13, July 1, 1922, pp. 639–645, 10 figs Description of steam-turbine plant with an ultimate capacity of 200,000 hp.; boiler room; electric generating equipment; control equipment.

STEAM TRAPS

Selection and Use. Steam Traps Their Selection, Installation and Upkeep, E. Smiley. Power, vol 56, no 2, July 11, 1922, pp 45–48 General consideration and method of distinguishing actual leakage of steam from vapor formed by re-evaporation

STEAM TURBINES

Exhaust Type. The Exhaust Steam Turbine, W. R. Woolrich Nat. Engr., vol 26, no 6, June 1922, pp. 250–252, 3 figs Why this type has proven economical in conjunction with steam engine, vacuum as factor in economy; performance data.

Flow Phenomena and Design. Flow Phenomena and the Design of Large Steam Turbines (Stromungsvorgänge und Aufbau grosser Dampfturbinen), G. Zerkowitz. Zeit des Vereines deutscher Ingenieure, vol 66, nos 22 and 23, June 3 and 10, 1922, pp 533–536, 561–565, 15 figs. June 3 Incomplete expansion; means for reducing wear of turbine parts. June 10 Limits of efficiency; effect of great lengths of blades on flow of steam, etc.

STEEL

Arc-Deposited. Properties of Arc Deposited Steel, O. H. Eschholz. Iron Age, vol 109, no 26, June 29, 1922, pp 1803–1805, 7 figs Cast and hammer forged metal under static and dynamic stress as produced by direct current and steel electrodes.

Electrolytic Building Up. A Successful "Putting On" Tool for Steel Parts, David R. Kellogg. Elec. Jl, vol. 19, no 6, June 1922, pp. 249–251. Satisfactory method for depositing metal where it has been removed by wear or inaccurate workmanship.

Fatigue. Fatigue in Annealed and Tempered Carbon Steels (Über die Ermudung gegluhter und verguteter Kohlenstoffstähle), W Muller and H. Leber. Zeit des Vereines deutscher Ingenieure, vol. 66, no. 22, June 3, 1922, pp. 543–546, 8 figs. Experiments with steels of various carbon content, relation between fatigue and tempering and mechanical properties of steel.

Identification by Spark. Steels and Their Sparks Metal Industry (Lond.), vol. 20 no 23, June 9, 1922, pp. 549, 551–552, 10 figs. Determining character of steel by examination of sparks given off when sample is held against abrasive wheel.

Stainless. Stainless Steels and the Making of Cutlery R. G. Hall. Am. Soc for Steel Treating Trans vol 2, no 7, Apr. 1922, pp. 561–565 and (discussion) 566–568, 6 figs. Manufacture of stainless-steel blade, while not materially different in shape or size from that of ordinary carbon steel blade, is shown to be a great deal more costly.

STEEL CASTINGS

Foundry For. Makes Valves in New Foundry, H R Simonds. Foundry, vol 50, no 11, June 1, 1922, pp. 431–435, 13 figs. Description of steel foundry built by Chapman Valve Co for manufacture of steel castings.

Manufacture. The Production of Light Steel Castings, H. Spencer Kipling. Metal Industry, vol. 20, no. 21 and 22, May 26 and June 2, 1922, pp. 493, 495 and 525–526. Suggestions for overcoming metal difficulties of making castings for this type.

STEEL, HEAT TREATMENT OF

Carbon- and Chromium-Molybdenum Steel. Effect of Heat Treatment on Mechanical Properties of a Carbon-Molybdenum and A Chromium-Molybdenum Steel, H. I French. Am. Soc. for Steel Treating Trans., vol 2, no 9, June 1922, pp. 769–797 and (discussion) 797–798, 17 figs. Summary of results of previous tests and comparison of treatments for production of high resistance to impact and best combination to strengthen ductility.

Cooling and Heating. The Proper Heating and Cooling of Steel, John A. Succop. Can. Machy., vol. 27, no. 22, June 1, 1922, pp. 42–44, 4 figs. Less trouble experienced with small masses; all portions of piece should be subjected to same temperature; human element weakest link; temperature and time most important factors. Paper read before Am. Soc. for Steel Treating.

Annealing Overstrained Steel. The Efficiency of Annealing Overstrained Steel, I. H. Cowdrey. Am. Soc. for Steel Treating Trans., vol. 2, no 9, June 1922, pp. 802–808, 3 figs. Tests made to determine extent to which treatment of overstrained steel is successful.

Magnetic Properties, Influence on. The Influence of Heat Treatment Upon the Magnetic Properties of Steel, Lancelot W. Wild Am. Soc. for Steel Treating Trans., vol. 2, no. 8, May 1922, pp. 696–704, 6 figs. Intensity of magnetization, permeability, residual induction, and coercive force. Bibliography.

STEEL, HIGH-SPEED

Tests, Physical. Physical Tests on High-Speed Steels, A. H. D'Arcambal Iron Age, vol 110, no 1, July 6, 1922, pp. 1–5, 7 figs Transverse and tensile tests of two grades compared; effect of these properties on service of tool.

STEEL MANUFACTURE

Direct Process. A Direct Method of Steel Manufacture, A. E. Bourcoud Iron Age, vol 109, no 20, May 18, 1922, pp 1319–1351, 3 figs. Discussion of Bourcoud process and possibility of using oil, lignites and other fuels; data on costs. (Abstract.) Paper presented at meeting of Am. Iron and Steel Inst.

Tropenas Converter. Tropenas Converter for Making Steel, S. R. Robinson Blast Furnace & Steel Plant, vol. 10, no. 5, May 1922, pp 282–284. General description of this process, details of converter and information regarding cupola change. This process is very similar to the bessemer process.

STEEL WORKS

Electrification. The General Effect of Electrification on the Operation of Steel Mills, W Sykes Blast Furnace & Steel Plant, vol. 10, no. 6, June 1, 1922, pp. 306–312. Some interesting figures on operation of mills at Mark Plant are included, writer believes electric power is more economical than steam power.

Calumet Steel Company Electrify Mills, L. H. Hook and F. R. Burt. Blast Furnace & Steel Plant, vol 10, no. 6, June 1, 1922, pp. 313–316, 1 figs Rotary converter adjustable speed sets as applied to rail rerolling mill; twelve stands of rolls are now electrically driven.

France. The Hagondange Works [Les Usines d'Hagondange (Moselle)], I Siegle. Révue de Métallurgie, vol. 19, no. 6, June 1922, pp 313–351, 27 figs Describes iron works of Union des Consommateurs de Produits metallurgiques et industriels, mines operated by company; blast furnaces worked, their operation; steam production and use, compressed air; electric current; Thomas converters, rolling mills; workmen's dwellings.

France. The Unieux Foundry and Steel Works (Les Forges et Aciéries d'Unieux). Outillage, Tome 260, no 20, May 20, 1922, pp 652–655, 13 figs. partly on supp. plate. Describes works established by Jacob Holtzer, situated in Ondaine Valley, near Firminy, France, and its equipment

STOKERS

Chain-Grate. A New Chain Grate Stoker. Mar. Engr. & Naval Architect, vol. 45, no 537, June 1922, pp. 246–247, 1 fig. Mechanical method of coal firing; self-cleaning features; application of chain-grate to marine boilers.

Selection. What to Know When Selecting Stoker Equipment, J. G. Worker. Power, vol. 55, no. 17, Apr. 25, 1922, pp. 647–650. Combustion characteristics of principal coals; types of stokers best suited to burn them.

STORAGE BATTERIES

Lead Hydrate. Some Reflections on the Lead Hydrate Accumulator, W. R. Cooper. Electrician, vol. 88, no. 2298, June 2, 1922, pp. 654–656, 1 fig Examination of claims made for new type and consideration of characteristics.

STREET RAILWAYS

Toronto's Rolling Stock. Toronto's Progressive Rolling Stock Elec. Ry. Jl., vol 59, no. 21, May 27, 1922, pp. 867–870, 10 figs. Toronto Transportation Commission has added 250 new cars to its passenger rolling stock and has remodeled more than 350 other cars.

Turnstile Cars. Improvement in Turnstile Cars. Elec Ry. Jl, vol. 59, no. 19, May 13, 1922, pp. 787–789, 6 figs. One-man operation with double-truck cars in Utica and Syracuse has increased steadily until now Utica has 100 per cent operation. Improvements in turnstile arrangement are described

STRESSES

Allowable, Safety and. Factors of Safety and Allowable Stress, C. D. Albert. Am. Mach., vol. 57, no. 2, July 13, 1922, pp. 54–57. Meaning of allowable stress; factors of safety for live and dead loads; effects of fatigue, shock, and uncertainy as to actual conditions existing.

Torsional. Torsional Stresses (Die Lehre der Drehungsfestigkeit), Constantin Weber. Forschungsarbeiten auf dem Gebiete des Ingenieurwesens, no. 249, 1921, 70 pp., 170 figs. Discusses phenomena of torsion, stresses occurring, conditions of equilibrium, internal change of form; develops formulas and makes calculations; application to various cross-sections.

Two-Dimensional. Some Special Cases of Two Dimensional Stress or Strain, C. E. Inglis. Engineering, vol. 113, no. 2945, June 9, 1922, pp. 732–733, 8 figs. Mathematical consideration in six special cases in plates.

SUBWAYS

Safety and Operating Developments, London. "Safety" and "Operating" Developments on the Underground Railways. Ry. Gaz., vol. 36, no. 22, June 2, 1922, pp. 891–894, 6 figs. Arrangements to cut off current from affected section in 20 to 25 seconds; controller governed by brake system; other features.

T

TAR

Preparation and Uses. Preparation and Uses of Tar and Its Simple Crude Derivatives, W. W. Odell. Bur. of Mines, Dept. of Interior, Technical Paper 268, 1922, 84 pp., 13 figs. General treatise on utilization of tar and usual methods of working up tar into some of its simple or easily prepared derivatives.

TANKS

Steel, Manufacture of. Role of Steel Tanks is Important, J. D. Knox Iron Trade Rev., vol. 70, no. 25, June 22, 1922, pp. 1795–1797 and 1806, 3 figs. Manufacturing methods are relieved of details by standardizing product; fabrication involves 24 distinct operations; how large oil tanks are erected; instructions for tank installation.

TELESTEREOGRAPHY

Belin System. Telegraphic Transmission of Photographs. Nature, vol. 109, no. 2743, May 27, 1922, pp. 687–688, 1 fig. Latest developments in which good results have been obtained by French wireless station near Bordeaux and naval station in United States.

TESTS AND TESTING

American Society. American Society for Testing Materials. Iron Age, vol 110, no. 1, July 6, 1922, pp. 13–18 Annual convention discusses steel castings and pig and cast iron; sulphur in steel; symposiums on impact testing and fatigue of metals.

TEXTILE INDUSTRY

British and American Practice. British and American Textile Manufacturing Practice, Wm. D. Hartshorne. Engrs. & Eng., May 1922, pp. 143–148, 6 figs. Characteristic qualities of wool fiber; comparison of its treatment and results of differences.

TIDAL POWER

Utilization. Utilizing the Power of the Tides and the Motion of the Sea Waves (Utilizzazione della forza delle maree e dell'urto delle onde del mare). Elettricista, vol. 1, no. 10, May 15, 1922, pp. 73–74, 2 figs. Various schemes for generating power; describes plant at Rennes, in France.

TIMBER

Creosoted, Fire Hazard. Are Many Creosoted Timber Structures Destroyed by Fire? Ry. Maintenance Engr., vol. 18, no 5, May 1922, pp. 167–169. Facts which show that advantages derived from preservative treatment far outweigh any possible hazzards from that source.

TIRES, RUBBER

Damaged, Inspection of. The Inspection o

Advance copies of the new enlarged and completely rewritten edition of Engineering Bulletin M-1, descriptive of Cadman Bearing Metals, were sent to a few prominent engineers. Here are their replies:

A Professor of Mechanical Engineering

"Your treatment of the subject is both interesting and logical. The bulletin contains more practical information than any text book with which I am familiar. I should like to have several additional copies for use in my classes, if you can spare them."

The Chief Engineer of a Power Company

"Your bulletin M-1 is valuable and I must frankly confess that I can now, for the first time, actually visualize what takes place in a bearing."

The Chief Engineer of a Company manufacturing Electrical Machinery

"Engineering Bulletin M-1 is the first trade publication I have received in which the subject is discussed rationally. It is of real scientific interest."

The Superintendent of Motive Power of a Railroad

"Your Engineering Bulletin M-1 is of interest. Please quote prices on your metals."

The Chief Engineer of a Company Manufacturing Gas Engines

"We have been using your metal for about twenty-five years in our heavy duty bearings, and have never had a complaint. I consider your bulletin a valuable addition to engineering literature and can heartily endorse all you say."

The Superintendent of a Steel Plant

"We have been using your metal for more than twenty years, and I am glad to learn why it gives so undoubtedly superior service to babbitts made in the usual way."

This new edition of Engineering Bulletin M-1 will gladly be sent to Consulting, Operating and Designing Engineers. Use the coupon.

(Clip the coupon or simply enclose your card in an envelope)

The Hydraulic Turbine in Evolution

New Problems Created by Turbine Evolution—Analysis of Flow in a High-Speed Turbine—Correlation of the Marine Propeller with the Hydraulic Turbine

By H BIRCHARD TAYLOR[1] AND LEWIS F. MOODY,[2] PHILADELPHIA, PA.

IF WE view the present stage of development of the hydraulic turbine against its historical background, there are many indications that we are in the midst of a transition period. There was a similar time of transition in 1890 to 1900 when the turbine was being developed to meet the requirements of electrical generation, and as pointed out in the paper by one of the authors presented last year,[3] one phase of that transition period was an increase in complexity marked particularly by the adoption of multi-runner units. Another transition occurred about 1911 to 1912, marked by a return to greater simplicity and the readoption of the single-runner vertical machine.

For almost ten years the hydraulic turbine remained nearly stationary in its development, accepted practice settled upon a nearly standardized design, and there seemed to be room for little further improvement in efficiency, speed, or mechanical design. Nevertheless within the last two or three years a surprising number of new lines of progress have been opened up and the turbine, and with it other features of water-power engineering, is again in a healthy state of change.

Notable progress has been accomplished by a number of engineers in the extension of the range of available speeds, so that extremely high specific speeds are now obtainable with satisfactory efficiency. The authors have for a number of years been devoting particular attention to this high-speed field and the possibilities which the extension of the field has opened up. This paper will describe some of the lines of development which have been followed and some of the problems involved in applying the new turbine forms which have been developed.

PROBLEMS CREATED BY TURBINE EVOLUTION

As an indication of what has been accomplished, Figs. 1 and 2 show in preliminary form the design of an installation now under construction involving a turbine runner which is within a few inches of the same diameter as that installed at the great Cedars Rapids plant on the St. Lawrence containing the largest runners in existence today. The turbine shown in these figures, however, is of very nearly twice the specific speed which was available at the time the Cedars turbines were designed. It should also be recalled that the specific speed adopted in the Cedars plant represented a notable step in advance at the time that installation was completed, namely, 1914. This ability to use double the speed which was available eight years ago represents a material saving in the cost of the turbines, generators and power-house structure.

Not only is the weight and cost of the generator reduced in even greater ratio than the saving in the turbine, but the reduction in weight of parts to be handled by the power-house cranes reduces the weight of the station superstructure, and it is also possible in installations now carried out to effect considerable savings in the amount of excavation necessary for the power-house substructure, to mention only a few of the principal factors affected by the recent progress. The turbine of Figs. 1 and 2 is of the diagonal-propeller type. As shown in Fig. 2, instead of employing the usual continuous "speed ring" at entrance to the guide vanes, the design involves the use of separate stay vanes. In addition to the stay vanes at entrance, a second series of stay vanes are used in the spreading draft tube, as shown in Fig. 1. Fig. 3 shows a 16-in. turbine of the same type tested in the I. P. Morris Laboratory.

Although great progress has been made in the attaining of higher speeds, another question remains to be investigated, and that is the extension of the application of these high-speed turbines to higher heads.

For a long time it was common practice to select the type of turbine for any installation by taking the value of specific speed from a so-called "experience curve" which was plotted between the variables: head and specific speed. Thus it was assumed that for any given head available for a projected plant, the specific speed adopted should not be higher than the limit shown by such a curve. But the specific speed permissible for any installation is not a function solely of the head on the plant but it is also dependent upon the elevation of the turbine runner with respect to the surface of tailwater. About all that can be said for the "experience curve," is that by its use, turbines can be selected for any given installation which will be capable of being set at some arbitrary height above the tailwater consistent with customary practice. This method, however, of selecting specific speeds for any projected plant is not of much value even as a rough approximation and should not be relied upon, since it neglects so many factors of importance, among them being the possibilities opened up by the latest advances in this field of engineering. For example, there are probably many plants where the elevation of the runner above tailwater has been placed at an arbitrary distance, where it would have been possible by lowering this elevation to permit the adoption of considerably higher speeds and at the same time to reduce the risk of corrosion and vibration.

Referring, for instance, to the type of turbine shown in Figs. 1 to 3, it may be pointed out that there is no strong necessity when this turbine is installed to place the runner above high tailwater level. The probability of emergencies arising which would require the shutdown of the unit for examination or repair is very slight in large modern installations of the high class of design and workmanship now available. It is therefore not likely that it will be necessary to gain access to the runner during times of abnormal height of tailwater. Moreover, in the new forms of high-speed turbines when built in the large sizes of units now being adopted, it is not necessary to provide a manhole for entrance to the draft tube below the runner, since this space is readily accessible through the wide openings between the runner blades. It is therefore possible in many plants to place the runners close to the normal tailwater elevation without likelihood of any serious inconvenience.

As mentioned in the paper of last year, moreover, a further departure from customary practice has been proposed by one of the writers, involving the placing of the runner below tailwater. This suppression of the runner may be accomplished either by providing tail-race gates to permit access to the runner, or by adopting the inverted arrangement of the turbine. As a matter of interest and to show some of the possibilities of this plan, Fig. 4 is given, representing a proposed arrangement of the Taylor inverted turbine. One of these turbines was tested with one runner in both the inverted and conventional positions in order to satisfy the skeptical that the performances would be identical—as they were.

[3] The Present Trend of Turbine Development, by Lewis F. Moody, MECHANICAL ENGINEERING, vol. 43, no. 4, April, 1921, p. 235.

Abridgment of a paper presented at a meeting of the Philadelphia Section of THE AMERICAN SOCIETY OF MECHANICAL ENGINEERS, Philadelphia, March 21, 1922.

Analysis of Flow in a High-Speed Turbine

In order that the questions raised by the use of the new turbine types under an increasing range of heads may be considered more in detail, the following method of analyzing the flow through a high-speed turbine is given.

In some aspects the high-speed turbine has approached the marine propeller, but while some forms of high-speed turbines resemble a marine propeller rather strikingly in appearance, there are essential differences in action. In the marine propeller the water approaches the propeller in directions parallel to the axis of rotation; in the high-speed turbine of Fig. 3, the water enters the turbine with radial inward components of velocity directed toward the axis and also with an increasing tangential or whirl component about the axis. The radial component is turned into a diagonal direction, and in this type this turning then proceeds continuously as the flow passes through the runner until the discharge becomes axial and finally outward, away from the axis. The flow as it progresses through the turbine can be thought of as containing three kinds of rotation, or whirl, which take place simultaneously about three different axes.

In the complete form of the turbine, such as shown in Figs. 1 and 2, the water enters the turbine through a volute casing in which it takes up a motion of rotation about the turbine axis, which is increased as the water passes through the stationary guide vanes and approaches the axis. This rotation may be called the "primary whirl." As shown in the paper of last year, this whirl, while partially abstracted by the runner, still persists in reduced degree in the draft tube. It has apparently been the effort of some designers to adapt their runners to remove all whirl from the water and to discharge the water without rotation, and many of the draft tubes now used or proposed are adapted to handle only non-whirling flow; and many of such draft tubes—especially the formerly prevalent elbow type—are very defective in operation with any kind of flow. It was demonstrated in the previous paper, however, that when a runner discharges into a draft tube which is capable of regaining the energy of whirl, the most efficient condition of operation of the runner is attained when the water is discharged in an oblique direction, containing a definite tangential velocity component about the axis. It therefore follows that a high-speed runner when equipped with a whirl-regaining draft tube will operate most efficiently at a higher speed and that its efficiency will then be higher than is possible with other types of draft tube. Indeed, if runners of the speeds now being used are installed with improperly designed draft tubes, serious loss of power and efficiency may be looked for, as well as vibration and unsteady operation.

In analyzing the action of this "primary whirl" which the water possesses in some degree throughout its passage through the turbine, the law of constancy of moment of momentum may be applied to all spaces in which the water can whirl freely without the influence of directing vanes or obstructions. In accordance with this law, the tangential velocity in such spaces will vary inversely as the radial distance from the axis. We may start to apply this principle to the flow in the volute casing of the turbine and may form the walls of the volute to conform with such a mode of flow.

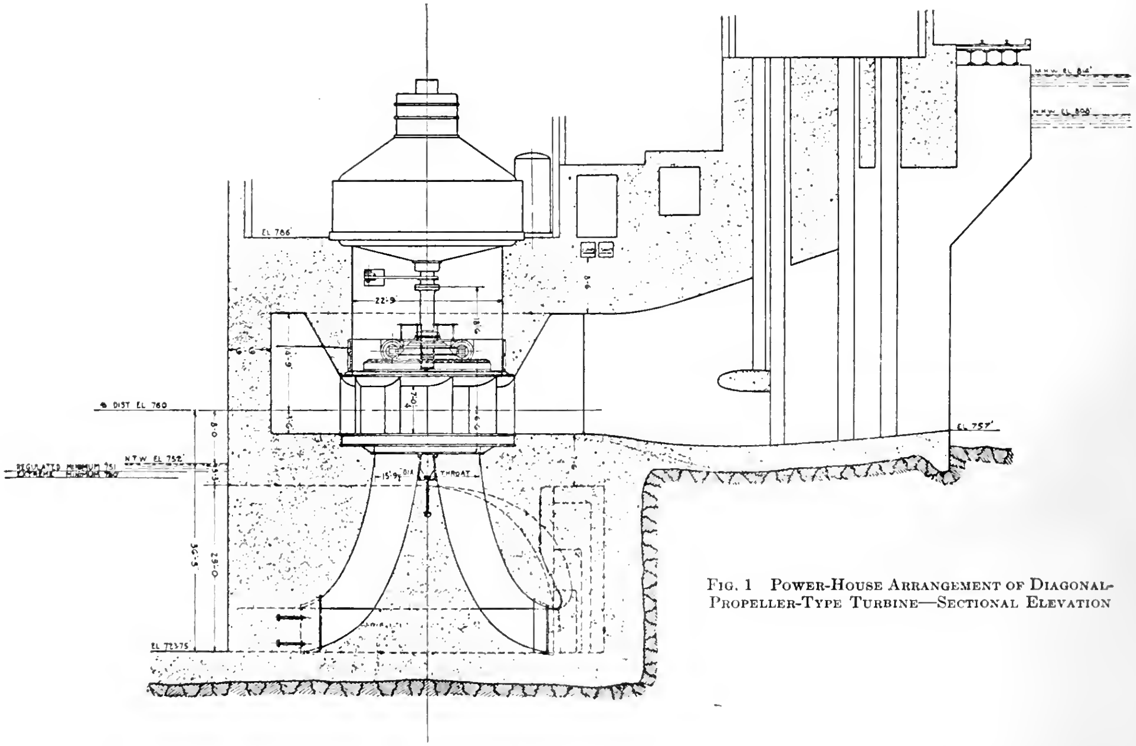

Fig. 1 Power-House Arrangement of Diagonal-Propeller-Type Turbine—Sectional Elevation

In designing the volute casing in this manner, the cross-sectional area of the volute passage will decrease in passing around the circumference of the turbine at a rate sufficient not only to provide for the decrease in quantity of flow remaining in the volute at each section, but also to provide for a continually increasing velocity. When applying this law to the velocity at any section, it may be taken as inversely proportional to the radius to the center of gravity of the section. In a casing designed by this method the walls will conform to the natural path of the water, and there is no reason to expect any greater loss of head in such a casing than that corresponding to the friction loss in an equivalent length of straight pipe.

After the water leaves the guide vanes, it passes inward toward the axis, its velocity continuing to increase in inverse proportion to the radius; and since more and more of its pressure head is converted into velocity head, its pressure decreases. If the freely whirling water is permitted to approach the axis closely, low pressures will occur, appreciably lower than atmospheric in many cases. Thus, we shall have even on the entrance side of the runner pressures of low absolute value, sometimes but little above the pressure in the draft tube; and this is evidenced in actual operation in some designs by the drawing of air through stuffing boxes into the transition space in advance of the runner.

Since points of low pressure are conducive to cavitation, or the formation of voids in the water stream, with tendencies toward

eddy formation, the formation of air pockets, and danger of corrosion and vibration, it is, of course, desirable to avoid any such low-pressure regions. An undue reduction in pressure in advance of the runner can be avoided by the admission of the water to the runner before it has approached too closely to the axis, the further reduction in pressure which the water must experience on its way to the draft tube then taking place within the runner during the process of transferring energy from the water to the runner. A reduction in pressure in advance of the runner is aggravated when the turbine is operating at part gate if it is equipped with the usual wicket gates, since at part gate the water leaves the guide vanes with increased velocity in a more tangential direction and with lower pressure, and the pressure starting at a lower value near the guide vanes drops more rapidly toward the axis. It may easily happen, particularly at part gate, that pressures may exist in the inner portion of the entrance space to the runner which are equal to, or even less than, the pressure in the draft tube. The new diagonal form in runner blade is adapted to prevent an undue pressure reduction of advance of the runner blades by providing a considerable diameter for the inflow edge of the blade where it joins the runner hub.

Another consideration which leads to the adoption of a diagonal-flow runner in preference to the purely axial-flow type is that as the stream elements at the upper portion of the guide vanes approach the axis the velocity of the water increases in inverse proportion to the radius. The velocity of the entrance edges of the runner blades, however, decreases in direct proportion to the radius, so that if the flow is carried too near the axis it may readily occur that the water will be traveling faster than the runner, requiring a backward angle of the runner blade and leading to complicated curvature and inefficient action. There is no necessity for the close approach to the axis, and by carrying the runner blades diagonally across the entrance passage an efficient runner has been produced and one having great mechanical strength due to the length and form of the blade section where it joins the runner hub.

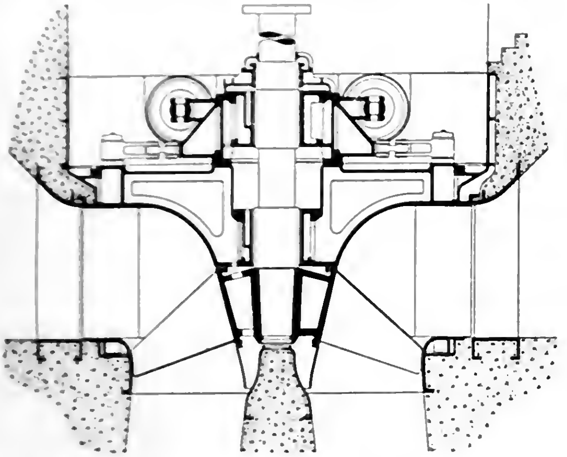

Fig. 2 Sectional Elevation of Diagonal-Propeller-Type Turbine

Since the primary whirl persists, although in reduced amount, at discharge from the runner, it is desirable, when structurally feasible, to provide in the draft tube a central core continuous with the runner hub. The provision of this core avoids the tendency toward the formation of a central cavity within the flowing stream with the resulting production of eddies, turbulence, and unsteady flow.

The second kind of whirl in the turbine occurs in meridian planes, that is, planes containing the turbine axis, and constitutes a rotation about axes perpendicular to these meridian planes. This rotation sets up an increase in pressure toward the upper and inner surface of the entrance space to the runner, and an increase in velocity and decrease in pressure at the lower distributor plate and runner tips. This "secondary" whirl therefore reduces the velocity of the stream elements leaving the upper part of the guide vanes and correspondingly reduces the velocity attained at entrance to the runner by these elements which enter the runner nearest to the axis; the stream elements leaving the lower end of the guide vanes are increased in velocity by this secondary whirl, but as these elements move inward toward the turbine axis only a small distance, their velocity is not further increased by any great amount.

The primary and secondary whirls, therefore, tend to some extent to neutralize each other in their effects of causing unequal distribution of the velocities and pressures in different portions of the stream. After turning the water from an inward direction to the axial, it then becomes desirable to turn the water outward and to conduct it away from the axis as an excellent means for regaining as much as possible of the energy of whirl with which it leaves the runner, while at the same time regaining the energy corresponding to the meridian component of velocity. The deflections from radial inward flow to axial flow and from axial to radial outward flow can very well be made continuous in a turbine designed to occupy small space in an axial direction. Fig. 3 shows such a design in which the secondary whirl is maintained and gradually reduced in magnitude as the flow attains the outward direction, without any abrupt changes in curvature of path.

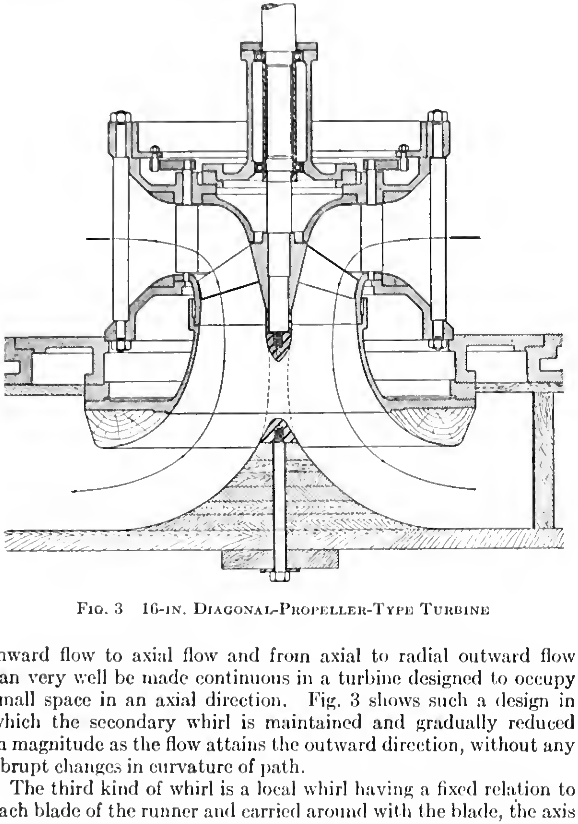

Fig. 3 16-in. Diagonal-Propeller-Type Turbine

The third kind of whirl is a local whirl having a fixed relation to each blade of the runner and carried around with the blade, the axis of this whirl being transverse to the general direction of flow and lying approximately in a revolving meridian plane. Consider the flow behind a blade, Fig. 5. The water adjacent to the rear surface of a blade will follow a curved path so that it may change in direction to correspond with the deflection produced by the blades and thus develop torque on the runner. The curvature of the path of successive stream elements will decrease at points receding from the blade, and at some distance from the blade the curvature will disappear. The flow behind each blade therefore contains a whirling motion approximating in some degree to a rotation about an axis normal to the plane of the figure. This axis may be taken as the center of an arc coinciding with the rear surface of the blade. If we apply to this local whirl the laws of a free vortex and suppose the velocity relative to the blade to vary inversely as the radial distance from the axis of rotation, we will have a picture of the flow sufficiently close to what probably occurs behind a blade to furnish us some useful conclusions. Such a local vortex at each blade would result in a local reduction of pressure on the back surface of the blade, and it is shown in the complete paper that the probable amount of such local pressure reduction is approximately equal to—

$$h_p - h_{pb} = \int_{r_b}^{r} \frac{w_b{}^2 r_b{}^2 dr}{gr^3} = \frac{w_2{}^2}{2g}\left(1 - \frac{r_b{}^2}{r_c{}^2}\right)$$

where h_p is the pressure head at any point in the stream, h_{pb} and r_b are the pressure head and radius at the back surface of the blade, r_c a radius dropped perpendicularly upon the center line of the preceding blade, and w_2 the relative velocity at the rear surface of the blade. This represents the amount by which the local pressure on the surface of each blade falls below the average pressure at the top of the draft tube. The actual amount of this reduction will vary greatly with the form, length, and spacing of the blades in any particular runner.

As any tendency of the water to leave the vane surface is believed to be conducive to cavitation, with resulting risk of corrosion and vibration, it is considered highly important to provide enough margin of pressure in the draft tube below the runner to take care of this local pressure drop, so that an adequate intensity of absolute pressure will still remain at the vane surface. This consideration requires that the runner be placed at an elevation above tailwater not exceeding a value consistent with the Bernoulli formula applied to the draft tube, with due allowance for the above local pressure drop.

One useful method of determining the allowance for the local pressure reduction is by referring to marine-propeller practice. Conservative practice in marine-propeller design dictates that the tip speed of the propeller should be kept below a fairly definite limit based on experience with actual propellers which have developed serious vibration or corrosion. If we express the local pressure drop in terms of velocity head corresponding to tip speed rather than to relative velocity, these velocities being not greatly different in propellers and high-speed runners, and if we assume that vibration and corrosion are due to cavitation produced when the local pressure at some point in the propeller or runner has been reduced to an extent sufficient to overcome the static pressure of the atmosphere and the depth of immersion of the top of the wheel, we can obtain an expression of the form—

$$\text{Local pressure drop} = (\text{a coefficient}) \times \frac{(\text{tip speed})^2}{2g}$$

in which the coefficient is determined by inserting in this formula the total static pressure at the top of a propeller and the corresponding tip speed which has been found to give safe protection against cavitation for ordinary forms of blades.

Although the allowance to be made in any given turbine installation depends on many factors, as already pointed out, the above will give a general idea of the magnitude of the effect of the local whirl or vortex at each blade.

One of the things to be avoided is an undue reduction in blade surface, particularly for turbines operating with inadequate margin of pressure in the draft tube. Insufficient blade area is not only conducive to cavitation at normal load, but gives rise to unsteady or unstable operation at part load. Evidently the driving torque on the runner is derived from the pressure difference between the face and back of blade, resolved into the tangential direction. If the angle of inclination of the blades is small with respect to the tangential direction and the blade area small, a high intensity of pressure increase is required on the blade face, and a high intensity of decrease on the back. A small number of narrow blades therefore magnifies the problem outlined above.

A comparison of the performance curves of a four-bladed, axial-type runner with those of a six-bladed diagonal runner shows that the axial runner has marked instability at small gates, while the curves of the diagonal runner are smooth and of normal form.

Reports have come to the authors of serious vibration in several high-speed installations. We may conclude from some of the considerations pointed out above that such vibration may be due to one of the following causes, or a combination of them: a defective

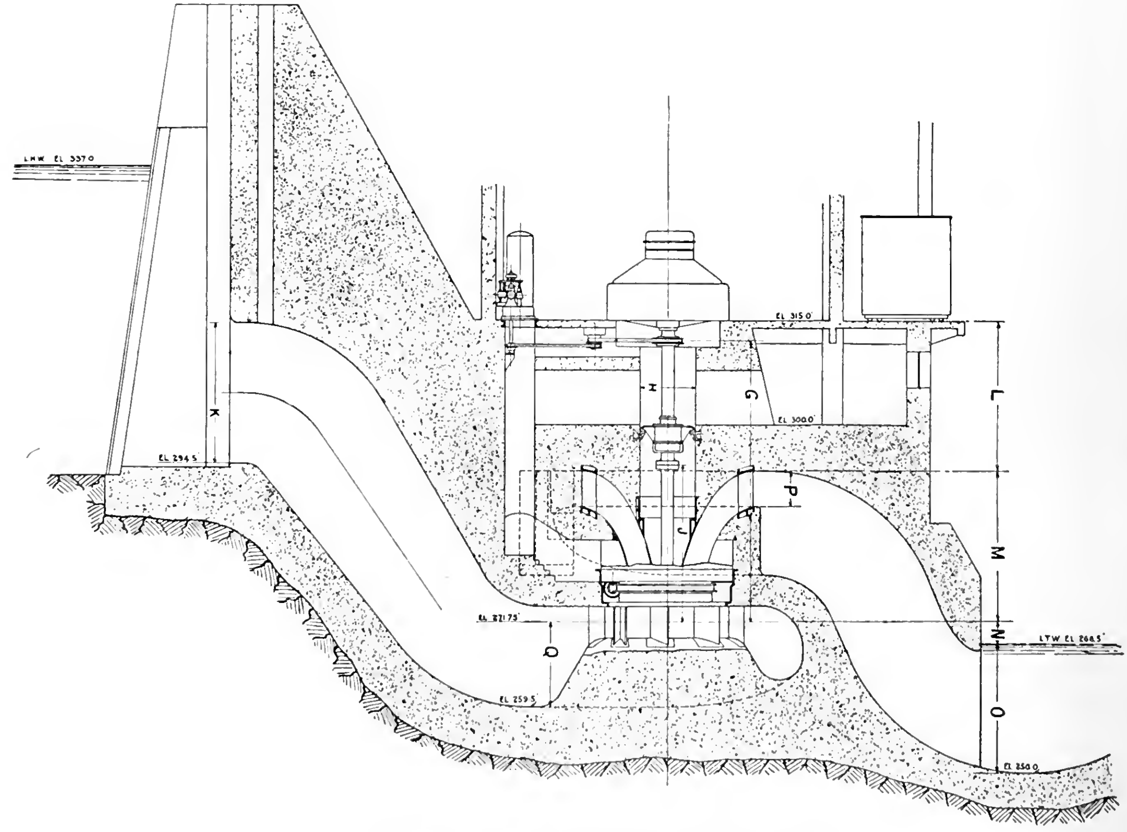

Fig. 4 Proposed Arrangement of Taylor Inverted Turbine

form of draft tube, excessive draft head, local cavitation, or unstable flow in the runner.

The high specific speeds now available involve other limitations besides those already mentioned. If extreme values of specific speed are adopted, a sacrifice in part-gate efficiencies must be accepted, but if the speed selected is within moderate bounds, very satisfactory performance curves are available. Fig. 6 shows a comparison of performance curves of a number of runners, all of 16 in. throat diameter, tested in the I. P. Morris Laboratory. Curves *A* and *B* are for runners of the so-called "Francis" type, or the usual mixed-flow, high-speed type of recent popularity. The runner corresponding to curve *B* is a model of the 16-ft.-diameter runners at Cedars Rapids, a larger model of which (of about twice the size of this one) gave 90 per cent efficiency at Holyoke; so that all of the results in Fig. 6 can be considered equivalent to some four or five per cent increase in a larger model. Curve *C* shows the performance of a runner of slightly over 100 specific speed (foot-pound system used throughout), and the excellent part-gate results will be noted. This is a diagonal-propeller-type turbine with a six-bladed runner operating with a spreading draft tube. Curve *D* corresponds to a turbine of the same type but of considerably higher specific speed (144), and its performance is also excellent. Curves *E* and *F* are for the same runner as *D*, but overspeeded, giving specific speeds of 180 and 225, with poorer performance, particularly at part gate. Curve *G* is for a four-bladed axial-type runner, with very poor part-gate results.

As it is believed that there is a tendency in a narrow-bladed runner for an eddy to form behind each blade at part gate and sometimes even at normal gate, one of the authors has proposed the use of secondary blades close to the main blades but slightly in advance of them, for the purpose of directing the flow more efficiently along the back of the main blade, and by this means eliminating instability and vibration and improving the part-gate efficiency, etc. Fig. 7 shows a four-bladed axial-flow runner equipped with such secondary blades, the two blades being in contact in the position shown. The secondary blade is of diagonal-flow form. It was found by tests that the addition of the secondary blades or "intervanes" reduced the specific speed, but increased the efficiency by 8 per cent and that it prevented unstable flow and vibration and inproved the part-gate efficiency. It was found that the best angular position of these blades was about 10 deg. in advance of their position of contact with the main blades. The field of usefulness of the idea has yet to be determined; it is merely presented here as a suggestion of interest.

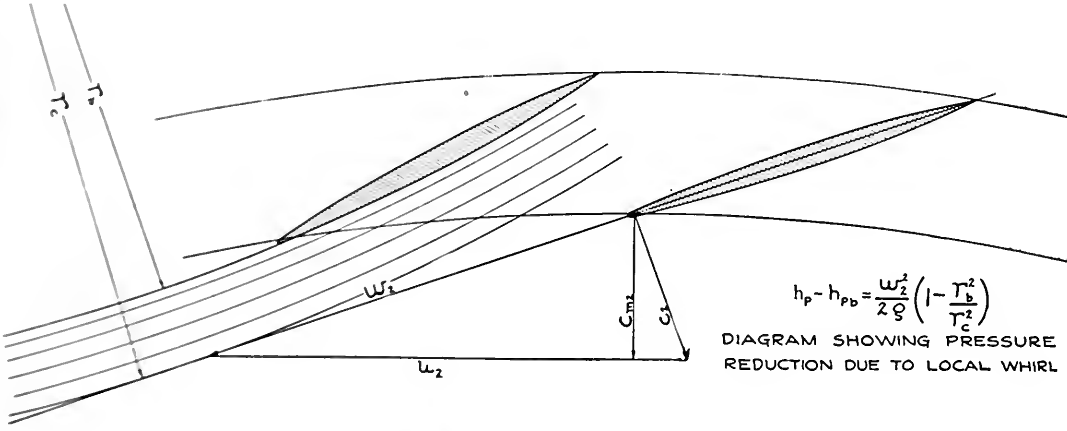

Fig. 5 Diagram of Local Vortex Behind Runner Blade

In order that the reader may appreciate the magnitude of the problems involved in applying the new turbine forms to large modern developments, it may be mentioned that the turbine of Figs. 1 and 2 will develop 28,000 hp. under 56 ft. head at a speed of $138^1/_2$ r.p.m.; and that this requires a tip speed of the runner of nearly 80 miles per hour or $1^1/_3$ miles per minute, more than the speed of the Broadway Limited. For comparison, the peripheral speed of the 55,000-hp. runners of the Queenston-Chippawa Development, operating under 305 ft. head, is only 67 miles per hour, and the circumferences of the 37,500-hp. runners of the Niagara Falls Power Company (214 ft. head) move at a rate of less than "a mile a minute."

Correlation of the Marine Propeller with the Turbine

We have already alluded to the similarity in general appearance of some of the new forms of high speed turbine to the marine screw propeller, and we have applied to turbines some of the conclusions from marine practice. It has probably occurred to many that there must be similarities in action between the new turbines and propellers; and although we have pointed out above several essential differences in the action of these devices, it has seemed to the authors that it would be worth while to investigate the performance of the propeller in its relation to the action of the turbine, to see whether it would not throw some light on the future possibilities open to us in the direction of further increases in specific speed, and on the probable forms to be looked for in turbines capable of developing higher speeds. We think that the results of this investigation are worth presenting here.

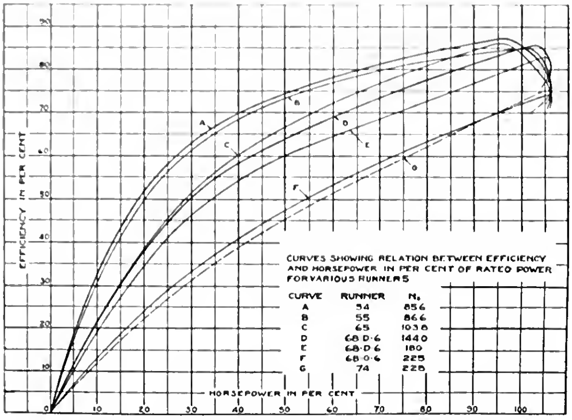

Fig. 6 Comparative Performance Curves of 16-in. Turbines of Different Specific Speeds

One difference between the turbine and the propeller is that the latter works in open water and is not enclosed. This difficulty can be met without introducing the probability of serious error by supposing the flow through the propeller to take place within definite imaginary boundaries, surrounded by water which does not partake of the action (See Screw Propellers for Hydraulic and Aerial Pro-

pulsion, second edition, by Rear-Admiral Charles W. Dyson, Fig. 1-A). A second difference—and one of considerable importance—is that the water enters the propeller with a high relative velocity and although the propeller increases this velocity and discharges the water at a still higher velocity, the relative discharge velocity is only moderately in excess of the speed of advance of the propeller. This excess represents an absolute sternward velocity, the head corresponding to which is a loss of energy corresponding to the "outflow loss" in a turbine. If the propeller should be considered, however, as operating as a turbine or pump, the head due to the entire relative velocity of discharge would represent a loss, unless the necessary step is taken of providing the device with a diffuser or draft tube to decelerate the velocity to a small value and to regain an adequate proportion of its energy. When operating as a propeller, therefore, there is on great need of a diffuser or draft tube; but the propeller cannot fairly be considered to be applicable as a turbine unless it is also supposed to be fitted with a draft tube. This change must be taken into account in giving the efficiency—the propeller ought to be credited with the loss of the entire head due to the absolute velocity of discharge, and charged with the loss which would be incurred in a draft tube of most approved form when handling the whole relative discharge velocity, the result being the efficiency of the equivalent turbine. If V is the speed of advance of the propeller through still water, c the absolute velocity of discharge, c_u its tangential component and c_m its axial or meridian component, the outflow loss of the propeller is—

$$\frac{c^2}{2g} = \frac{c_u^2 + c_m^2}{2g}$$

and that of the equivalent turbine is—

$$f\frac{(V + c_m)^2 + c_u^2}{2g}$$

in which f is the proportion of the velocity head lost in diffusion—which will here be taken as 20 per cent, corresponding to an ordinarily efficient draft tube.

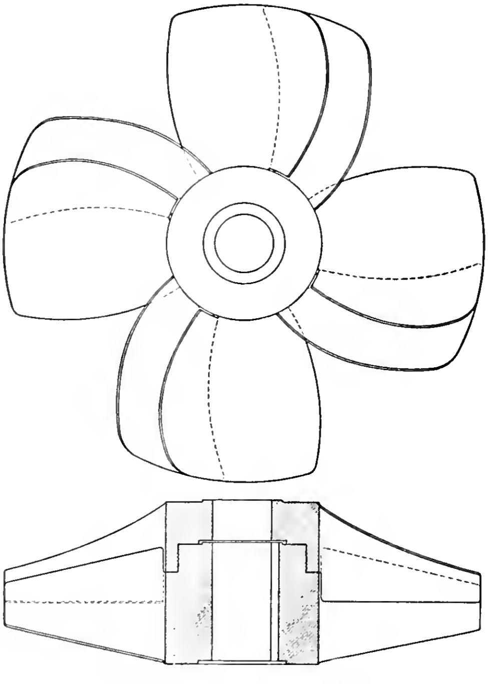

Fig. 7 Moody Intervane Runner

The first quantity which it is necessary to calculate is the head, a quantity which does not appear in the ordinary propeller calculations. Defining the head as the energy per pound of water passing through the wheel, we can distinguish three values of head: the transmitted or equivalent head H_e, that is, the head corresponding to the mechanical horsepower transmitted by the propeller shaft, and from the wheel to the water, or in a turbine from the water to the wheel; the lost head, made up first of internal losses in the wheel due to surface friction of the blade surfaces, impact or eddies, which we shall include in the term L, and the outflow loss L_1, which we have already seen is equal to $c^2/2g$; and finally, the delivered head H_1, corresponding to the horsepower realized in the thrust of the screw acting through the distance per second equal to the speed of advance. Evidently—

$$H_e - L - L_1 = H_1 \text{ and } \frac{H_1}{H_e} = e_1$$

where e_1 = propeller efficiency.

It is shown in the complete paper that $H_1 = T/WA$, where T is the axial thrust, lb.; W the weight of water per cu. ft.; and A the disk area of the propeller $= \pi R^2$, where R is the blade-tip radius.

To visualize the relation of H_e, H_1 and lost head the diagram of Fig. 8 (a) is given, in which H_1 is shown as the portion of H_e remaining after deducting the losses L and L_1.

For completeness, we have shown in the same figure diagrams (b) and (c) representing the relation of heads in the propeller working as a pump and a turbine respectively. The only modification in changing from (a) to (b) is that instead of a total rejection of the outflow loss $c^2/2g$, the pump, equipped with a diffuser, loses the fraction f of the entire discharge velocity head relative to the system—

$$f\frac{(V + c_m)^2 + c_u^2}{2g}$$

When operating as a turbine, however, as represented at (c) the equivalent head (or in this case the effective head) H_e corresponding to the energy transmitted by the shaft is that portion of the total initial head H_3 which remains after deducting the losses L and L_2. In all three modes of operation, we can suppose the same quantity of water to be passing through the wheel, the same power being transmitted by the shaft, and therefore the same equivalent head H_e being involved. (We can suppose the blade angles to be adjusted to keep Q the same.) Since the velocities are the same, L is constant throughout, and L_2 is the same at (b) and (c).

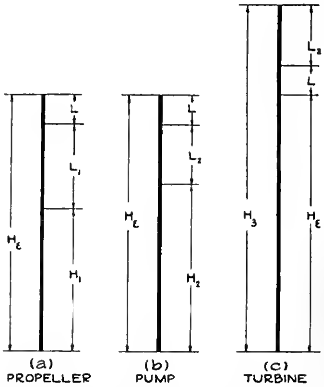

Fig. 8 Diagram Showing Relation of Heads in Propeller, Pump and Turbine

The efficiencies for the three cases are

$$(a)\ e_1 = \frac{H_1}{H_e}; \quad (b)\ e_2 = \frac{H_2}{H_e}; \quad (c)\ e_3 = \frac{H_e}{H_3};$$

and the specific speeds as a pump and turbine, respectively are—

$$(b)\ N_{sq} = N\frac{\sqrt{Q}}{H_2{}^{3/4}}; \quad (c)\ N_{sq} = N\frac{\sqrt{Q}}{H_3{}^{3/4}} \text{ and } N_s = N\frac{\sqrt{\text{S.Hp.}}}{H_3{}^{5/4}}$$

(N_{sq} indicating the specific speed based on quantity of discharge, used in pump practice and N_s the ordinary specific speed as used in turbine practice, expressed in the foot-pound system.)

The remaining steps to complete the calculation of the above results are the determination of c_m, c_u, L_1 and L_2.

In figuring either the moment of momentum or the kinetic energy of the discharge, we can assume for simplicity that the result is the

same as if the whole flow were concentrated at about seven-tenths the radius of the wheel, giving —

$$c_u = \frac{gM}{WQ\ (0.707)\ R}$$

where M is the torque or moment of tangential forces; and from—

$$c_m = \frac{gT}{WQ}$$

we obtain —

$$L_1 = \frac{c^2}{2g} = \frac{c_u{}^2 + c_m{}^2}{2g}$$

For the propeller tests used c_u is found to be small. We then have, referring to Fig. 8 (a)—

$$L = H_e - L_1 - H_1$$

$$L_2 = f\frac{(V + c_m)^2 + c_u{}^2}{2g}$$

(using 0.20 for f), and —

$$H_1 = H_e + L + L_2$$

from which we immediately obtain e_s and N_s.

The method of calculation formulated above has been applied numerically to the series of propellers tested by Admiral Taylor,[1] and the specific speed and efficiency corresponding to operation as a turbine have been computed for various values of slip for those models which gave the higher values of efficiency. The results are given in Fig. 9, which is a chart showing the relation between efficiency and specific speed for three ranges of specific speed, namely, the range corresponding to the turbines of the usual or so-called Francis type; the range so far covered by the high-speed propeller type; and finally the values calculated according to the above method for marine propellers operating as turbines. The turbine efficiencies shown on the chart, some of which are from recent tests, were all secured on 16-in. turbines tested in the I. P. Morris laboratory. It happens that Admiral Taylor's propeller tests were also made on wheels of 16 in. diameter, so that all of the results plotted are properly comparable. While the turbine performances plotted, which are indicated in solid lines, are actual test results, the curves computed from propellers, and shown in dotted lines, are inferred or theoretical values derived from the test results by the method indicated in the above analysis.

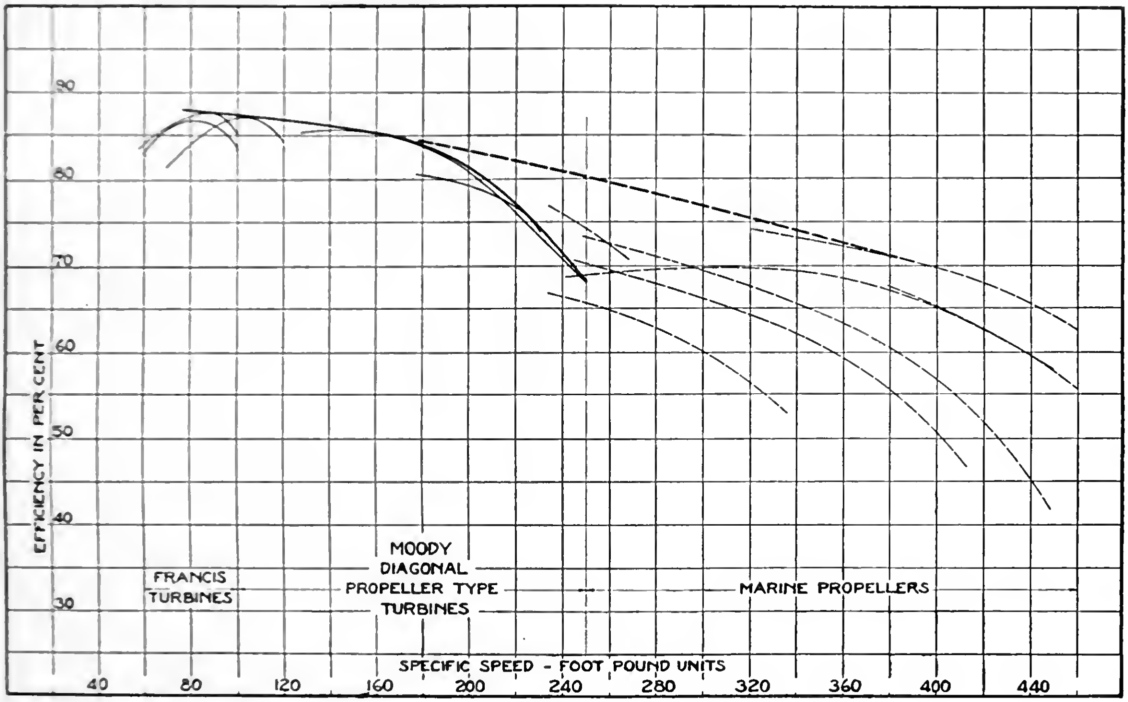

Fig. 9 Chart of Efficiency and Specific Speed for High-Speed Turbines

While there are a number of reservations which should be kept in mind in comparing the turbine and propeller performances to take account of some of the differences pointed out above, such, for example, as an allowance for the difference between the friction of a solid confining wall and the loss due to the turbulence of a flowing stream passing through still water, it is, however, believed that the relations presented in the chart are of considerable interest and significance. It will be noted that the general trend of the envelope representing the highest efficiencies at various specific speeds is very similar to the form of curve presented in the paper of last year by one of the authors, in which the theoretically possible efficiency was computed for various specific speeds. From the internal losses in the propeller due to blade friction, etc., the value of the coefficient f_2 used in last year's paper can apparently be somewhat reduced for the propeller-type turbines, giving a generally higher range of possible efficiences.

In addition to computing the efficiencies corresponding to various specific speeds derived from the propeller tests, the velocity head of the water at discharge from the runner and the allowance for local cavitation have also been computed and from these has been worked out the elevation at which the runner should be set with reference to tailwater in order to permit the propeller to operate as a turbine at the specific speeds shown. These results are presented in Fig. 10, which is a chart showing the relation of runner elevation to specific speed corresponding to three different values of the head on the plant selected by way of illustration. The chart shows, therefore, the probable effect of further increases in specific speed on the turbine setting. In order that these speeds may be safely realized, the values computed as above call for the turbine to be set at elevations not higher than those shown on the chart. These runner elevations are based on what the authors believe to be conservative practice within the field so far developed in actual turbines and similarly computed for the higher specific-speed field corresponding to the marine propellers. Under the higher heads and specific speeds it

[1] D. W. Taylor: Some Recent Experiments at the U. S Naval Basin. Paper before Society of Naval Architects and Marine Engineers, Nov. 17–18, 1904.

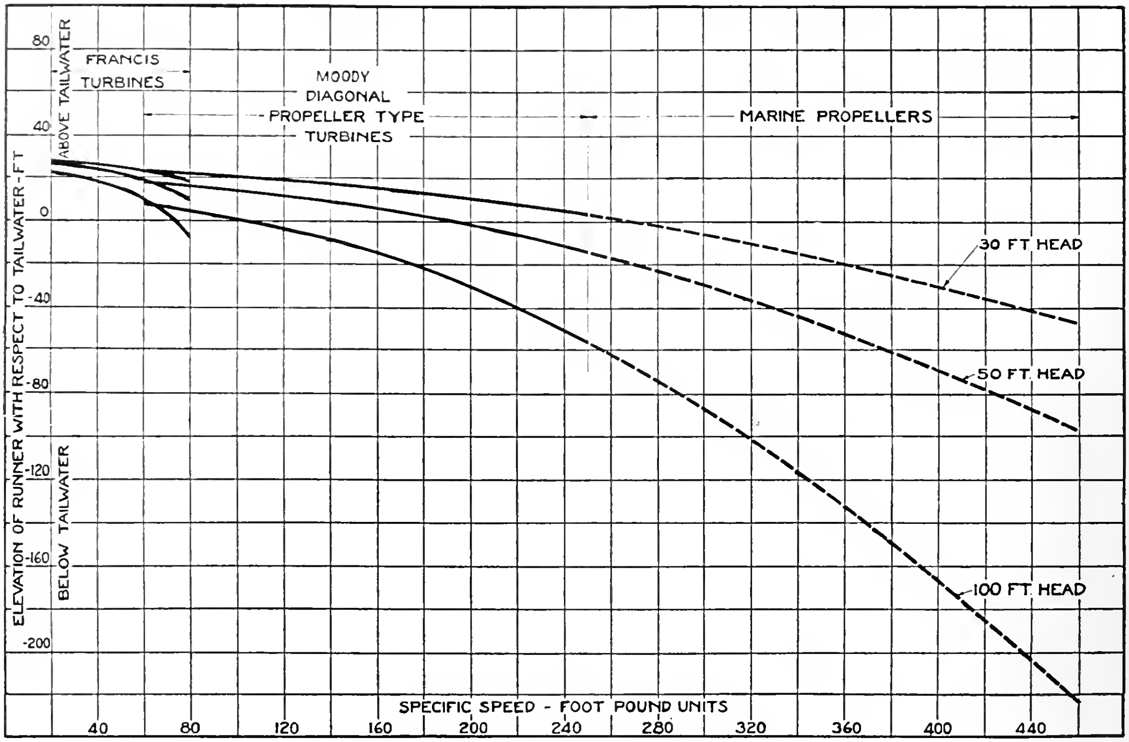

FIG. 10 CHART OF RUNNER ELEVATION AND SPECIFIC SPEED

will be noted that it would be necessary to place the runner far below tailwater and for the moderate conditions the runner would have to be placed close to the tailwater level, and in many cases somewhat below it. As has been previously shown, this is not impracticable.

It is believed that the above investigation of propeller performance throws some new light on the relation of turbine performance to that of pumps. It is also thought to be of interest to view the full range of turbine performance shown by Fig. 9, as indicated by the values of specific speed, with the corresponding values calculated for other classes of power machines. Table 1 has therefore been computed, indicating in a general and approximate way the comparative fields occupied by various machines, including hydraulic and steam turbines, pumps, air compressors and blowers, and the performance of marine propellers according to the above calculations for operation in ship propulsion, and as turbines and pumps.

TABLE 1 FIELDS OCCUPIED BY VARIOUS CLASSES OF MACHINES, COMPARED ON BASIS OF SPECIFIC SPEED

Class of Machine	Range of Specific Speeds Based on Power $N_s = N \frac{\sqrt{HP}}{H^{5/4}}$		Range of Specific Speeds Based on Quantity $N_{sq} = N \frac{\sqrt{Q}}{H^{3/4}}$
	Ft-lb. units	Metric units	Ft-lb. units
Hydraulic Turbines:			
Impulse turbines; single-nozzle Pelton wheels.	up to 8	up to 35	up to 25
Multiple-nozzle Pelton wheels or extreme low-speed Francis reaction turbines.	8 to 11	35 to 50	25 to 35
Reaction turbines, Francis type	11 to 95	50 to 425	35 to 300
Do., propeller type.	95 to 225	425 to 1000	300 to 750
Pumps:

Operating as propellers.	. . . . . .	. . . . . .	2600 to 3700
Operating as pumps (inferred performance).	. . . . . .	. . . . . .	1600 to 3000
Operating as turbines (inferred performance).	240 to 440	1070 to 2000	800 to 1600

(*a*) Based on values from article by K. Baumann entitled, Some Recent Developments in Large Steam-Turbine Practice, in *Engineering* (London), April and May, 1921. (*b*) Based on values from article by M. C. Stuart entitled, Centrifugal Fan Calculations by the Specific-Speed Method, in *Jl. Am. Soc. Naval Engrs.*, vol. 28, no. 3, August, 1916.

For the purpose of comparing prime movers, and pumps or compressors, the specific speed based on quantity has been used, as was done in the paper (The Present Trend of Turbine Development) delivered last year. The values given in the table are necessarily approximate, and are merely expressed in round numbers, since there are no exact limits to the specific speeds developed by a given class of machines, and the values stated meerly indicate those corresponding to the field of normal design.

The values shown on the chart of Fig. 9 seem to hold out much promise for further increases of very appreciable amounts in turbine speeds, for they show sufficiently high efficiencies to make the use of considerably higher speeds feasible, particularly in low-head plants where a saving in cost of machinery often justifies a sacrifice in efficiency. While the chart suggests the possibility of increases in speeds, the authors believe that the application of such increases should be made with caution and particularly that the extension of the use of these high-speed turbines to higher heads should be limited to the range of specific speeds for which high efficiencies have been actually developed by tests. Low efficiency points to the presence of eddies and disturbances in the turbine and should be regarded as a danger signal. Even when efficiency is not a vital consideration in itself (which is seldom true), low efficiency provokes other troubles which may be serious. In the authors' judgment therefore, the utilization of still higher speeds, which from the above investigation would appear to be attainable, should be made contingent upon the development of high efficiencies.

Semi-steel is the name popularly applied to the metal resulting from the use of mild steel added to the pig irons and scrap melted in the cupola or furnace. The percentage of steel used varied from 15 to 40 per cent, the lower figure for light work and the higher proportions for heavier castings. It is stronger than usual gray cast iron as regards transverse, tensile, compression and impact tests. It is superior in regard to elasticity, toughness, resistance to shock and wear. It has proved satisfactory for such castings as cylinders, pistons, gear wheels and castings called upon to withstand wear and friction. J. Cameron, in *The Engineer* (London), Aug. 11. 1922, p. 149.

High-Pressure Steam-Heating Lines

Effect of Throttling Through a Reducing Valve or Steam Motor—Economy of Generating Steam at High Pressure and Transmitting It Through a Small Line with Large Line Drop

By EDGAR BUCKINGHAM,[1] WASHINGTON, D. C.

A LETTER recently[2] referred to the writer contained the following requests for information: "We should be pleased to have such advice and references as to permit of our estimating the economy in steam production on a large scale which would be occasioned by generating and delivering steam for vulcanization at 45 lb. per sq. in. as compared with generating at 190 lb. per sq. in. and delivering at the lower pressure mentioned by throttling through a reducing valve." "Would not a steam engine or turbine, for example, functioning as a reducing valve between 190 and 45 lb. per sq. in. deliver a considerable power output without appreciably reducing the heat-supplying power of the low-pressure steam as compared with the ordinary reducing valve?" "When steam is used for purely heat-supplying purposes, does the use of a reducing valve over a considerable pressure range involve any real efficiency loss, or does the superheat due to throttling bring the available energy practically back to its original status?"

The engineer to whom the reply was sent wrote: "The conclusions you have reached are indeed surprising, and I trust that you will find the opportunity to prepare them for publication." Without knowing whether the conclusions in question are really novel, the writer submits the substance of his reply in the hope that if these deductions from very elementary principles are known by experiment to be incorrect, the facts may be brought out, for the public benefit, by some one who knows what the facts are.

THE NATURE OF THE THROTTLING PROCESS

The throttling process does not in itself cause any change in the "total heat" of the steam; and if the steam is to be used solely for heating purposes, i.e., only as a carrier for heat, the use of a reducing valve has no direct effect on the economy of the process, although there may, of course, be indirect effects on boiler efficiency and line losses, caused by the difference between generation and transmission at high pressure and at low.

The simplest way to look at the matter is as follows: We start with water at 45 lb. per sq. in. gage (60 lb. per sq. in. abs.) and the corresponding boiling point which is 292.7 deg. fahr. We put heat into this water in the boiler; convert it into steam at any pressure we please above 45 lb. per sq. in.; run it through a transmission line to a different place; condense it to water at the original temperature and pressure; and finally feed it back into the boiler.

During this process, aside from the insignificant work of the boiler-feed pump, no outside work is done either on or by the steam. Frictional work against the line resistance is merely dissipated into heat which stays in the steam, and does not count as outside work. A sudden large drop through a reducing valve is precisely equivalent to a great amount of line resistance concentrated in a short length of line. No *outside* work is done, and the kinetic energy generated at the valve is dissipated into heat which stays in the steam and dries or superheats it.

Since, therefore, the steam, in going round its closed cycle and returning to its original state of water at 45 lb. per sq. in. gage and 292.7 deg. fahr., does no outside work and has none done on it, the total amount of heat put into it must also be zero; otherwise the steam could not return to its initial state.

It follows that the heat put into the water in the boiler (plus the small heat equivalent of the work of the feed pump) is equal to the sum of the heat loss to the outside and the heat given up in the condenser—in this case the vulcanizer. This remains true no matter what the upper pressure may be, so that the economic questions to be considered in deciding on what pressure to use, relate to boiler efficiency, heat losses, and overhead.

If the steam is generated at an unnecessarily high pressure, which requires reduction before the steam is admitted to the vulcanizer, the reducing valve may be replaced by a steam engine or turbine. This will give a certain amount of outside work and the heat remaining in its exhaust to be given up in the vulcanizer, will be correspondingly diminished. If the bearing losses of the motor all stayed in the steam, the reduction in the heating value of the steam by its passage through the motor would be exactly the heat equivalent of the work delivered by the motor outside the bearings. Bearing losses which do not go back into the steam as reheat are equivalent to so much heat lost to the outside. They are to be added into the heat loss from the motor, which is itself merely one element of the heat loss from the whole system.

CALCULATIONS DEALING WITH THROTTLING IN THE LINE

To illustrate quantitatively, we will suppose that the vulcanizer requires 1,000,000 B.t.u. per hour, which are to be given up by steam at 45 lb. per sq. in. gage condensing at its saturation temperature of 292.7 deg. fahr. We shall consider three cases: (*a*) generation and transmission at 45 lb. per sq. in. gage; (*b*) generation and transmission at 190 lb. per sq. in. gage, with throttling to 45 lb. per sq. in.; (*c*) the same as (*b*) with the substitution of a reciprocating engine or turbine for the reducing valve. We shall suppose, in each case, that the boiler furnishes dry saturated steam, and we shall neglect pressure drop in the transmission line, and heat losses to the outside. Numerical data on steam are from the Marks and Davis tables.

In case (*a*), dry steam at 45 lb. (60 lb. per sq. in. abs.) arrives at the vulcanizer. Its latent heat is 914.9 B.t.u. per lb., so that the amount of steam needed is—

$$M_a = 10^6/914.9 = 1093 \text{ lb. per hour}$$

The furnace has, in any case, to supply to the water the whole 10^6 B.t.u. per hour plus the outside heat loss. The work of the feed pump would be zero if there were no line drop, and is insignificant in any event.

Turning to case (*b*), the total heat of water at 45 lb. per sq. in. gage and its saturation temperature 292.7 deg. fahr. is $H_0 = 262.1$ B.t.u. per lb. The total heat of dry saturated steam at 190 lb. per sq. in. gage and 384 deg. fahr. is $H_1 = 1198.5$. The heat supplied in the boiler is therefore $H_1 - H_0 = 936.4$ B.t.u. per lb. This difference consists of 95 B.t.u. per lb. needed to heat the water from 292.7 deg. to 384 deg., and 841.4 B.t.u. per lb. which is the latent heat of evaporation at 190 lb. per sq. in. gage. If there are no heat losses, the 936.4 B.t.u. per lb. are available for heating the vulcanizer, so that the amount of steam needed is—

$$M_b = 10^6/936.4 = 1068 \text{ lb. per hour}$$

When the dry saturated steam at 190 lb. is throttled to 45 lb. its temperature falls to 334.7 deg., but it is superheated 42 deg. Before beginning to condense, it must cool to 292.7 deg., and in so doing it gives up $936.4 - 914.9 = 21.5$ B.t.u. per lb. in addition to the 914.9 which it will give up as latent heat of condensation. To put it in another way, the dry steam at 190 lb. carries $936.4/914.9 = 1.024$ times as much heat available for extraction at 45 lb. as does dry steam at 45 lb.; so that the amount needed is only $1093/1.024 = 1068$ lb. per hour.

In case (*c*), if the dry saturated steam at 190 lb. per sq. in. gage were to expand isentropically to 45 lb. its total heat would fall from 1198.5 to 1102.1 and the difference, or 96.4 B.t.u. per lb., is the "available heat drop" which could be turned into outside work by an ideally perfect motor. The dryness factor of the steam after this expansion through a perfect engine would be 0.918; and the heat remaining available upon condensing to water would be $0.918 \times 914.9 = 840.0$ B.t.u. per lb. which added to the 96.4 makes up the 936.4 originally available.

Supposing that the motor extracts, say, 0.6 of the maximum possible—corresponding to 60 per cent indicated efficiency in the

---

[1] Physicist Bureau of Standards. Mem. Am.Soc.M.E.

[2] This was written in July, 1920.

case of a reciprocating motor—the heat drop of the steam in passing through the motor will be 0.6 × 96.4 = 57.8 B.t.u. per lb., so that the total heat of the exhaust is 1198.5 − 57.8 = 1140.7 B.t.u. per lb. And since the total heat of water at 45 lb. is 262.1, the heat available in the exhaust for use in the vulcanizer is 1140.7 − 262.1 = 878.6 B.t.u. per lb., the dryness factor of the exhaust being 878.6/914.9 = 0.960.

The amount of steam needed in this case would be, for a motor of 60 per cent indicated efficiency,

$$M_c = 10^6/878.6 = 1138 \text{ lb. per hour}$$

as compared with M_b = 1068 when a reducing valve was used. The indicated power of the motor would be 1138 × 57.8/2543 = 25.9 hp.

The pump work needed to put the condensate at 45 lb. back into the boiler at 190 lb. is less than 0.5 B.t.u. per lb., so that we have been justified in ignoring it.

Pressure Drop and Heat Loss in the Transmission Line

We may now turn to the question of pressure drop and heat loss in the transmission line, and we shall assume that no motor is to be used so that we have only to compare generation and transmission at a trifle above 45 lb. per sq. in. gage, with generation and transmission at 190 lb. followed by throttling to 45 lb. Leaving aside the question of capital charges, we shall consider only the heat losses per foot length of the transmission line, assuming that the different lines are all equally well insulated. We may say, as an approximate rule for practical purposes, that the heat loss per foot of pipe in B.t.u. per hour will be proportional to the diameter of the pipe and to the difference between the steam temperature and the temperature of the surroundings.

From this rule it is evident that increasing the pressure (and temperature) of the steam in the line increases the heat loss from a line of given size. But if the high-pressure line can be made small enough the reduction in surface will more than offset the increase of temperature difference, so that the losses may be less at the high pressure. The question, then, is whether the high-pressure line can be made small enough.

We here come to an essential difference between heating lines and power lines. In designing a power line the pressure drop along the line, which is merely distributed throttling, must be kept low because throttling diminishes the available heat drop that remains for the motor to work on. But in a high-pressure heating line followed by a reducing valve this limitation on the design is absent; for, aside from the heat losses, it makes no difference at all whether the necessary throttling takes place at a reducing valve or is distributed along the transmission line as line drop. The line drop may therefore be made large, leaving only enough drop at the reducing valve to take care of overload.

This plan seems to present several advantages. In the first place, the line can be made small and its surface reduced. Then the wire drawing in the line tends to dry or superheat the steam, which, of itself, reduces the ease of transmission of heat from the steam to the pipe. Moreover, the wire drawing, while it superheats the steam, reduces its temperature and so again decreases the heat loss. It appears, therefore, that a high-pressure heating line should be designed on entirely different principles from a power line. The line should be as small in diameter as practicable, the limit being set either by the necessity of having some drop remaining at the reducing valve, or, more probably, by the erosion of the line, which may become troublesome when the steam speed is run up very high.

Illustrative Computations of Pressure Drop and Heat Loss

It may be worth while to make some sample computations to illustrate the foregoing. Let D equal the inside diameter of the pipe in ft., S the linear speed of the steam in ft. per sec., M the mass flow in lb. per hour, and v the specific volume of the steam in cu. ft. per lb. Then we have—

$$M = 3600\,\frac{\pi}{4}\,D^2\,\frac{S}{v} = 2827\,\frac{D^2S}{v} \text{ lb. per hour} \ldots\ldots [1]$$

whence—

$$S = (Mv/2827D^2) \text{ ft. per sec.} \ldots\ldots\ldots\ldots\ldots [2]$$

Let P be the pressure drop per foot length of the line. Then since the steam speed is to be high so that the resistance is nearly proportional to the square of the speed, we have, approximately,

$$P = \text{const.} \times S^2/Dv \ldots\ldots\ldots\ldots\ldots\ldots [3]$$

where the value of the constant depends on the roughness of the pipe line as well as on the unit used for P. Eliminating S we have—

$$P = \text{const} \times M^2v/D^5 \ldots\ldots\ldots\ldots\ldots\ldots [4]$$

whence—

$$D = \text{const.} \times (M^2v/P)^{1/5} \ldots\ldots\ldots\ldots\ldots [5]$$

To use this equation for designing purposes we should have to take a value of the constant from known experimental results; but for our present purpose of comparing different sets of conditions we only need to assume that it is the same for the different lines compared; i.e., that the lines are similarly rough. If the subscripts 1 and 2 refer to the two sets of conditions, we then have for the ratio of the pipe diameters—

$$\frac{D_1}{D_2} = \left\{\left(\frac{M_1}{M_2}\right)^2 \times \frac{v_1}{v_2} \times \frac{P_2}{P_1}\right\}^{1/5} \ldots\ldots\ldots\ldots [6]$$

an equation which we may proceed to apply to numerical examples.

Let our two sets of conditions be: transmission at 45 lb. per sq. in. gage; and transmission at 190 lb. followed by throttling to 45 lb. We have already found in an earlier paragraph that M_{45}/M_{190} = 1093/1068; and from the steam tables we find that v_{45}/v_{190} = 7.17/2.237. Substituting these values in Equation [6] we have—

$$\frac{D_{45}}{D_{190}} = 1.26\left\{\frac{P_{190}}{P_{45}}\right\}^{1/5} \ldots\ldots\ldots\ldots\ldots [7]$$

Equation [7] tells us that if the line drop is to be the same in both lines so that $P_{45} = P_{190}$, the diameter of the low-pressure line must be 1.27 times that of the high-pressure line. The steam temperatures are 384 deg. and 293 deg., respectively, and if we assume an outside temperature of, say, 80 deg. we shall have approximately—

$$\frac{\text{heat loss at 45 lb.}}{\text{heat loss at 190 lb.}} = 1.26 \times \frac{293 - 80}{384 - 80} = 0.89$$

Hence if the lines were designed for equal total line drop, the low-pressure line, under ordinary outside conditions, would lose something like 10 per cent less heat than the high-pressure line.

But suppose that we let the drop be 10 times as great in the high- as in the low-pressure line, so that $P_{190} = 10P_{45}$. Then Equation [7] gives us D_{45}/D_{190} = 2.02, and in this case for 80 deg. outside temperature we have approximately—

$$\frac{\text{heat loss at 45 lb.}}{\text{heat loss at 190 lb.}} = 2.02\,\frac{293 - 80}{384 - 80} = 1.41$$

so that the heat loss would be considerably less for the *high*-pressure line. The figures are, of course, only roughly approximate, but they suffice to show the advantage of using high-pressure transmission with a small pipe and large line drop, altogether aside from questions of the capital cost of the line.

Although we have no precise data which would enable us to estimate the probable change in the combined furnace and boiler efficiency caused by changing from low to high pressure, it would seem, in view of the foregoing reasoning, that unless the transmission line is very short, a properly designed high-pressure plant may be made decidedly more economical in operation than a low-pressure one for the same heat supply to the vulcanizer.

Summary

The information requested may be summarized as follows:

a The use of a reducing valve in a steam-heating line does not, in itself, have any effect on the economy of the heating.

b If a steam motor is substituted for the reducing valve, the heating value of its exhaust is decreased by the amount of heat turned into work by the motor.

c Line drop is merely distributed throttling and has no direct effect on the final heating value of the steam.

d By generating at high pressure and transmitting through a small line, with large line drop, the heat loss from the line may be made much smaller than when the pressure is low throughout the system.

Forces in Rotary Motors

A Paper Dealing with the Determination of the Forces in a Rotary Motor Caused by the Reciprocation of the Pistons and Connecting Rods and by the Rotation of the Motor as a Whole, in Which Novel Methods of Calculation Are Employed

By KARL H. WHITE,[1] KEYPORT, N. J.

THE object of this paper is to present methods of determining the turning effort and the inertia and shaking forces of the pistons and connecting rods in a rotary motor, the LeRhone 9-cylinder 80-hp. internal-combustion motor being used as a concrete example. The data on this motor are given in Table 1.

The Indicator Card

From the data given in Table 1 the indicator card shown in Fig. 1 may be implied.

$$V = \frac{667}{9} = 74.11 \text{ cu. in.}$$

$$\text{Clearance} = \frac{74.11}{4.8} = 15.43 \text{ cu. in.}$$

Total volume of cylinder = 89.54 cu. in.

In Fig. 1—

$$\frac{P_b}{P_a} = \left(\frac{V_a}{V_b}\right)^n$$

Assuming an intake pressure of 13 lb. per sq. in. and $n = 1.35$ according to good practice,

$$\frac{P_b}{13} = \left(\frac{89.54}{15.43}\right)^{1.35}, \quad \text{whence } P_b = 139.8 \text{ lb. per sq. in.}$$

It can be shown theoretically that the mean effective pressure is equal to—

$$P_m = \frac{P_x V_x - P_x \frac{P_a}{P_b} V_d - P_b V_x + P_a V_d}{(n-1)(V_d - V_x)}$$

Substituting known values and employing a card factor of 0.96,

$$\frac{84}{0.96} = \frac{15.43 P_x - \dfrac{13 \times 89.54 P_x}{139.8} - 139.8 \times 15.43 + 13 \times 89.54}{0.35\,(89.54 - 15.43)}$$

whence—

$$P_x = 459 \text{ lb. per sq. in.}$$

The equation PV_n = Constant may be plotted as a straight line with a slope n on logarithmic cross-section paper. Plotting the compression and expansion curves in this manner the pressure P_d at d may be obtained from the expansion curve, as the pressure P_x at x and slope n are given.

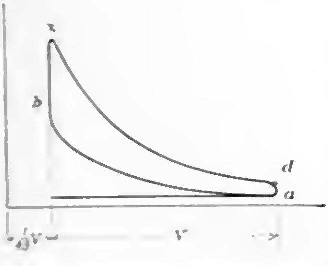

Fig. 1 Preliminary Indicator Card

TABLE 1 DATA ON THE LE RHONE 9-CYLINDER 80-HP. MOTOR INVESTIGATED

Speed	1200 r.p.m.
Direction of rotation	Normal (counterclockwise from propeller end).
Bore of cylinders	4.1339 in.
Stroke	5.512 in.
Length of connecting rods	9.6458 in.
Compression ratio	4.8
Piston displacement (9 cylinders)	667 cu. in.
Order of firing	1, 3, 5, 7, 9, 2, 4, 6, 8
Mean effective pressure	84 lb. net
Weight of engine dry	245 lb.
Weight of engine in running order, less fuel, oil and tanks	270 lb.
Weights of parts:	
Piston, with piston rings (each)	1.727 lb.
Wristpin with wristpin retainer screw	0.363 lb.
Inner connecting-rod assembly (each)	1.203 lb.
Center connecting-rod assembly (each)	1.240 lb.
Outer connecting-rod assembly (each)	1 340 bl.

The theoretical and actual indicator card may now be constructed as shown in Fig. 2.

Inertia Forces of Pistons and Connecting Rods

In order to obtain the inertia forces of the pistons and connecting rods, it is first necessary to obtain the absolute accelerations of these parts, because $F = MA$, where F = inertia force, M = mass, and A = absolute acceleration.

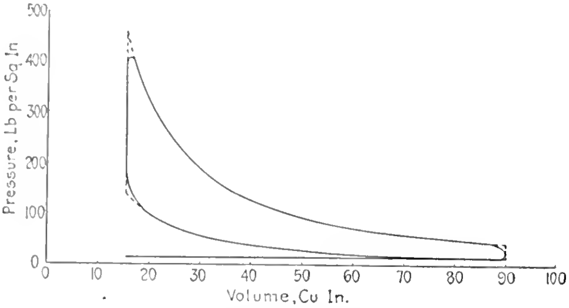

Fig. 2 Indicator Card for LeRhone 80-Hp. Motor
(Theoretical card also includes dotted areas.)

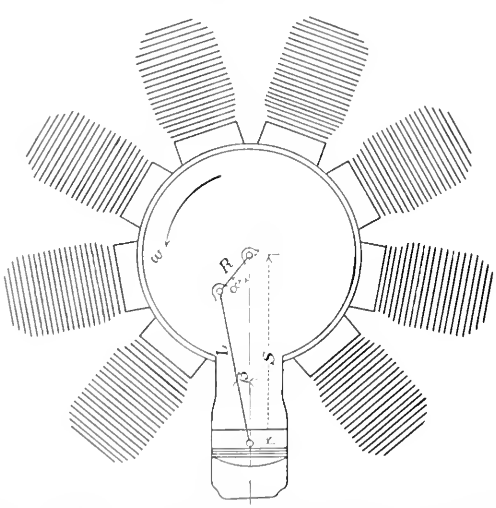

Fig. 3 Diagrammatic View of One Connecting Rod of LeRhone 80-Hp. Motor

Inertia of Pistons. The absolute acceleration of the piston is rather complicated, but may be found by using Coriolis' law.[1] According to this law, the absolute acceleration may be divided into three parts:

a The acceleration of a point on the cylinder opposite the center of gravity of the piston toward the center of rotation $= S\omega^2$. See Fig. 3.

b The acceleration of the piston relative to the cylinder, $= dS/dt$.

c Twice the product of the velocity of the piston relative to the cylinder, (U), and the angular velocity, $= 2U\omega$.

From Fig. 3, it will be seen that—

[1] See Kinematics and Kinetics of Machinery, by Dent and Harper.

$$S = R\cos\alpha + L\cos\beta$$

also $$\sin\beta = \frac{R}{L}\sin\alpha$$

hence $$\cos\beta = \sqrt{1 - \frac{R^2}{L^2}\sin^2\alpha}$$

Since $(R\ L)^2\sin^2\alpha$ is a small term, we may write with sufficient accuracy—

$$\cos\beta = \sqrt{1 - \frac{R^2}{L^2}\sin^2\alpha} = 1 - \frac{R^2}{2L^2}\sin^2\alpha$$

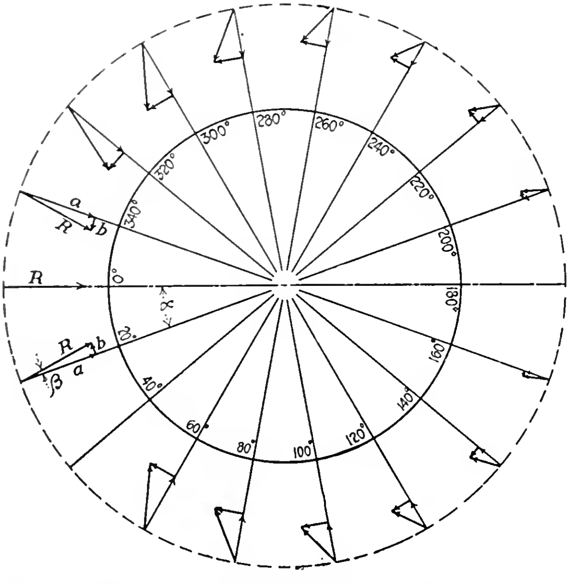

Fig. 4 Acceleration Diagram of Piston, Showing Direction of Resultant

This is equivalent to adding the small quantity $\frac{R^2}{4L^4}\sin^4\alpha$ under the radical.

Substituting this value for cos β,

$$S = R\cos\alpha + L\left(1 - \frac{R^2}{2L^2}\sin^2\alpha\right) \qquad [1]$$

The velocity of the piston relative to the cylinder is—

$$\frac{dS}{dt} = U = -R\,\omega\left(\sin\alpha + \frac{R}{2L}\sin 2\,\alpha\right) \qquad [2]$$

The second derivative of S with respect to time is equal to the acceleration of the piston relative to the cylinder, or—

$$\frac{d^2S}{dt^2} = -R\,\omega^2\left(\cos\alpha + \frac{R}{L}\cos 2\,\alpha\right) \qquad [3]$$

The negative sign simply indicates the direction of the acceleration.

Let us now rotate the motor through one revolution and consider accelerations every ten degrees.

Crank length = 0.2297 ft.

Length of connecting rod = 0.8038 ft.

$$1200 \text{ r.p.m.} = \frac{2\,\pi \times 1200}{60} = 126 \text{ radians per sec.} = \omega$$

From Equation [1]—

$$S = 0.2297\cos 10° + 0.8038\left(1 - \frac{0.2297^2}{2 \times 0.8038^2}\sin^2 10°\right)$$
$$= 1.027 \text{ ft.}$$

From Equation [2]—

$$U = 0.2297 \times 126\left(\sin 10° + \frac{0.2297}{2 \times 0.8038}\sin 20°\right)$$
$$= 6.45 \text{ ft. per sec.}$$

From Equation [3]—

$$\frac{d^2S}{dt^2} = \frac{dU}{dt} = 0.2297 \times 126^2\left(\cos 10°\ \frac{0.2297}{0.8038}\cos 20°\right)$$
$$= 4575 \text{ ft. per sec.}^2$$
$$S\omega^2 = 1.027 \times 126^2 = 16{,}300 \text{ ft. per sec.}^2$$
$$2U\omega = 2 \times 6.45 \times 126 = 1625 \text{ ft. per sec.}^2$$

From Coriolis' law, 2 $U\omega$ is at right angles to $S\omega^2$ and $\frac{dU}{dt}$, and the absolute acceleration R of the piston is the vector sum of these three quantities.

As $S\omega^2$ and $\frac{dU}{dt}$ are in the same direction at this position of the motor,

$$R = \sqrt{\left[(S\omega^2) + \frac{dU}{dt}\right]^2 + (2U\omega)^2}$$
$$= \sqrt{(16{,}300 + 4{,}575)^2 + 1625^2}$$
$$= 20{,}900 \text{ ft. per sec.}^2$$

R may be determined graphically, however, with sufficient accuracy.

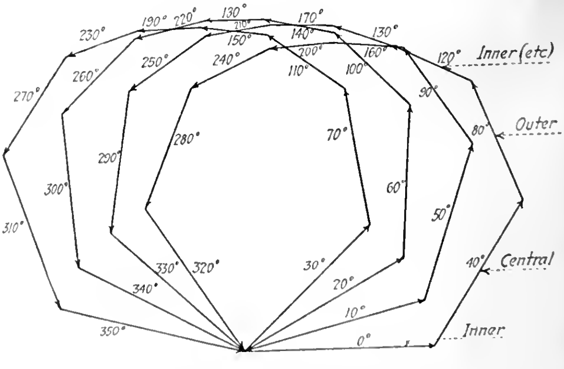

Fig. 5 Acceleration Polygons for Pistons

In a similar manner the absolute acceleration of the piston is found for every 10 deg. rotation of the motor, the results being given in Table 2.

Fig. 4 is an acceleration diagram of the piston showing the direction of its absolute acceleration. If we now plot acceleration polygons of the pistons at any particular position of the motor, we can determine the amount and direction of any shaking force due to the inertia of these pistons. Such polygons are plotted in Fig. 5; the vectors representing the absolute accelerations of the nine pistons at the particular instants of rotation of 0, 10, 20, and 30 deg. The polygons are similar to inertia polygons because the masses of the pistons are constant. From this figure it is seen that there are no unbalanced piston inertia forces, and consequently

no shaking force coming from the reciprocation of the pistons. This figure shows the magnitude of the compound supplementary acceleration, which has heretofore been neglected in similar calculations.

Let us now determine the actual inertia force of the piston per square inch of piston area and plot this force on an indicator diagram.

The total weight of a piston is 2.090 lb.

The inertia force at any instant equals 2.09/32.2 times the acceleration of the center of gravity of the piston along the line of stroke at that particular instant. The center of gravity of the piston assembly is considered at the center of the piston pin.

In Table 3 this inertia force is given for every 10 deg. rotation of the motor.

TABLE 3 INERTIA FORCE OF PISTON

Fig. 6 is a total-pressure diagram of a piston developed on a base line, representing the total motion of the piston relative to the cylinder (disregarding reversals) in two revolutions of the motor. In this diagram gaseous forces tending to help the motion of the piston and inertia forces tending to resist the motion of the piston are plotted above the base line. Gaseous forces tending to resist the motion of the piston and inertia forces tending to help the motion of the piston are plotted below the base line. These two force curves are combined to represent the resultant net piston force, as shown by the heavy lines. The resultant net piston force is plotted above the base line if tending to help the motion of the piston, and below if tending to resist the motion of the piston.

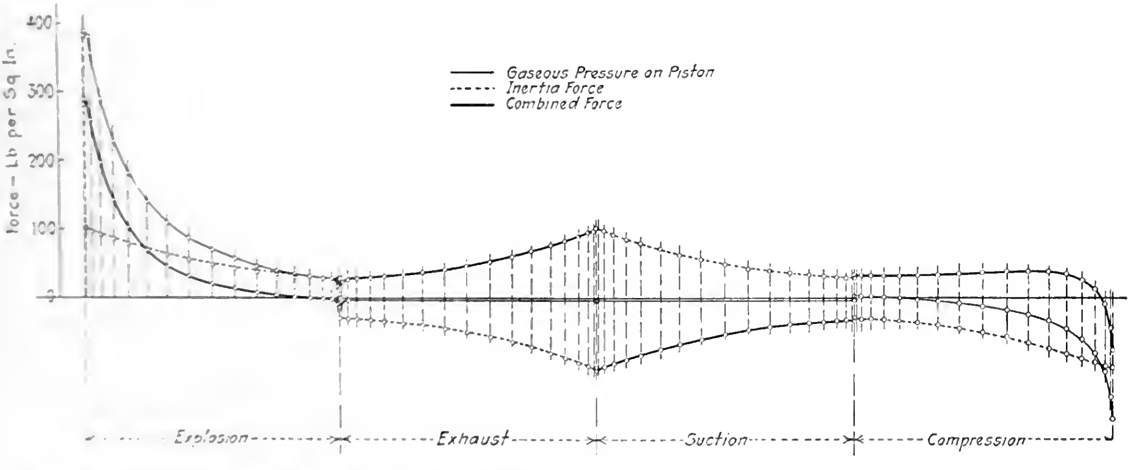

Fig. 6 Diagram of Gaseous Pressure on Piston, of Inertia Force of Piston, and of Combined Gaseous and Inertia Forces

Fig. 6 shows that due to the inertia of the piston there is as much work done on the exhaust stroke as on the explosion stroke. It also shows that the inertia force compresses the gas on the compression stroke. On the other hand, during the explosion and suction strokes this inertia greatly hinders the motion of the piston.

Inertia of Connecting Rods. In order to determine the inertia forces of the connecting rods, it is first necessary to find their centers of gravity. The connecting rods are accordingly laid out full size and sections are taken at intervals. The area of each section is calculated and plotted as an ordinate from a base line. The areas of the figures obtained represent the volumes of the connecting rods. Fig. 7 shows the layout for the inner connecting rod.

The area of each section is now multiplied by its distance from the end of the connecting rod, and this product, which is the moment of that area about the end of the rod, is plotted as an ordinate from a base line. If each of these last areas obtained be divided by the first areas, the distances of the centers of gravity from their respective connecting-rod ends are determined. The center of gravity as found for the inner rod is shown in Fig. 7.

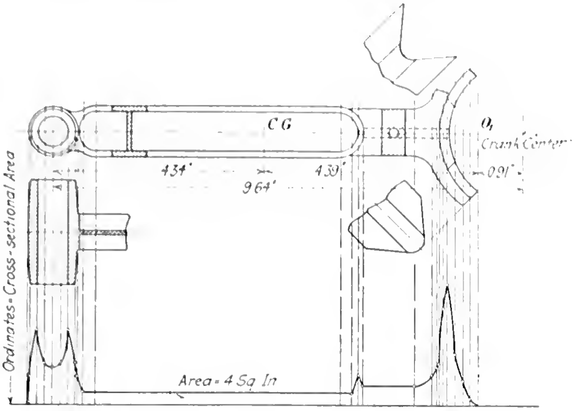

Fig. 7 Inner Connecting Rod and Volume Diagram

Let us now consider the accelerations of the connecting rods. From Fig. 7 the center of gravity of the inner connecting rod is 55 per cent of the distance from the crank center to the center of the piston pin. Therefore the acceleration of the center of gravity of this connecting rod is 0.55 times the acceleration of the piston and lies in the same direction at any instant. Similarly, the accelerations of the central and outer connecting rods are found to be respectively 0.548 and 0.53 times the acceleration of the piston, and in the same direction.

The accelerations and inertia forces of the connecting rods for every 10 deg. rotation of the motor are given in Table 4.

Knowing the magnitude and direction of these inertia forces, an inertia polygon may be plotted showing the resultant unbalanced inertia force of the connecting rods at any instant. Such a polygon is shown in Fig. 8 for angles of rotation of 0, 10, 20 and 30 deg. Due to the difference in weights of the connecting rods, the polygons do not quite close.

TURNING EFFORT

The turning effort of a rotary motor, according to the manner in which this paper is planned, is dependent upon three separate forces:

1 The net force on the piston acting toward the center of rotation and transmitted along the connecting rod.

2 The compound supplementary inertia force $2U\omega m$, which, according to Coriolis' law, acts at right angles to the velocity of the piston and in such a direction that it tends to rotate the velocity vector of the piston in the direction of rotation of the motor.

3 The inertia force of the connecting rod acting in the same direction as the resultant inertia force of the piston.

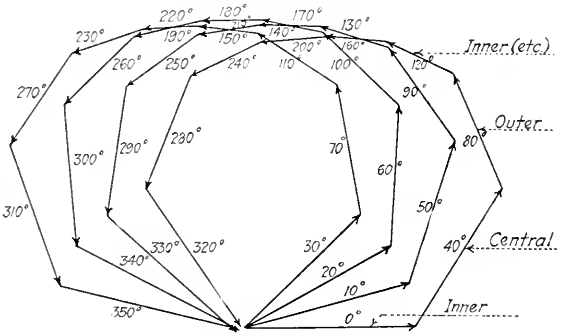

Fig. 8 Inertia Polygons of Connecting Rods

By simply determining now the moment arm of the first two forces, we have that much of the turning effort; but in order to get the turning effort caused by the third force, it is first necessary to get the moment of inertia of the connecting rod about its center of gravity.

Moment of Inertia and Radius of Gyration of Connecting Rods. If the ordinates of the moment diagram mentioned earlier be multiplied by their distances from the ends of the connecting rods, and these products be plotted as ordinates on another base line, the area formed is the moment of inertia, I_0 of that connecting rod about its end 0, for:

$$I_0 = \Sigma MX^2 \text{ or } \Sigma VX^2.$$

From such a diagram it is found that for the inner connecting rod

$$I_{01} = 123.74 \text{ volume inches}^2$$

Also—

$$I_g = I_0 - Vh_3^2 = Vk^2$$

where I_g = moment of inertia about the center of gravity
V = volume of connecting rod
k = radius of gyration
h_3 = distance from center of gravity to point about which the moment of inertia is taken.

From Figs. 7 and 9—

$$I_g = 123.74 - 4 \times 4.39^2 = 46.54 \text{ volume inches}^2$$

$$k^2 = 11.635 \text{ sq. in.}$$

Similarly, for the central rod,

$$I_g = 43.83 \text{ volume inches}^2;\ k^2 = 10.28 \text{ sq. in.}$$

and for the outer rod,

$$I_g = 40.98 \text{ volume inches}^2;\ k^2 = 8.196 \text{ sq. in.}$$

[1] Turning effort is positive up to 180 deg. and negative from 180 to 360 deg. as shown in Fig. 4.

Turning Effort of Connecting Rods. The simplest way of now determining the turning effort caused by the inertia of the connecting rods is by the Kinetically Equivalent System Method.

A kinetically equivalent system is a group of bodies rigidly connected together which will be given the same acceleration as an actual link under the action of the same forces. To meet this requirement, three conditions must be fulfilled:

1 The two systems must have the same mass
2 The two systems must have the same center of gravity
3 The two systems must have the same moment of inertia.

The simplest kinetically equivalent system which can be substituted for the connecting rods is shown in Fig. 9. It consists of two heavy particles m_1 and m_2 connected by a weightless link. Then, to satisfy the conditions of equivalence:

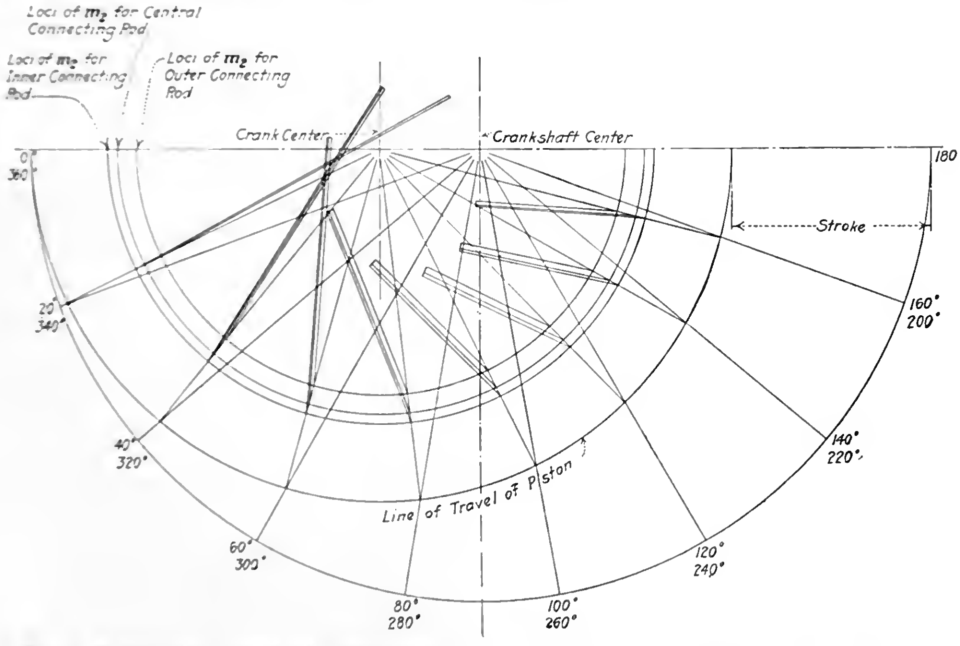

FIG. 10 MOMENT-ARM DIAGRAM FOR INERTIA FORCE OF KINETICALLY EQUIVALENT SYSTEM OF CONNECTING RODS

$$m_1 + m_2 = m \quad [4]$$

$$m_1h_1 = m_2h_2 \quad [5]$$

$$m_1h_1^2 + m_2h_2^2 = I = mk^2 \quad [6]$$

Eliminating the masses m_1, m_2 and m, Equation [6] reduces to $h_1h_2 = k^2$. Assuming any convenient value for h_1, h_2 can be found, thus locating the masses m_1 and m_2.

The mass m_1 is taken at the crank center so that it has no acceleration, and therefore it also has no inertia force. The mass m_2, its distance h_2 from the center of gravity of the connecting rod, and the inertia of the connecting rods can now be found. For the inner connecting rod—

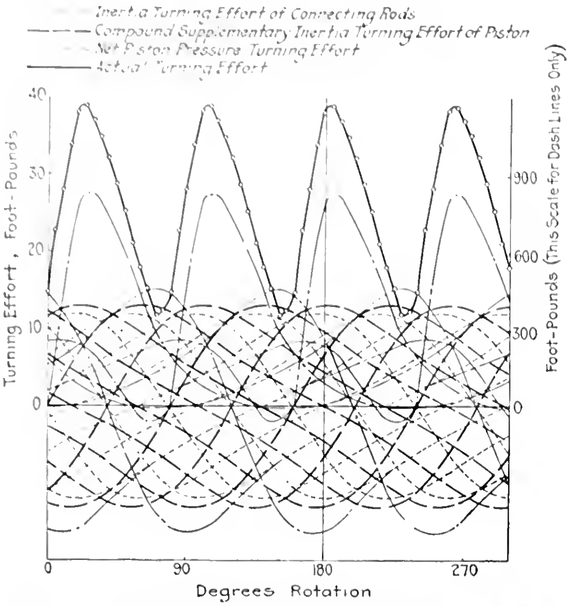

FIG. 11 TURNING-EFFORT DIAGRAM OF LERHONE 80-HP. MOTOR

$$h_1h_2 = k^2 \text{ and } h_2 = \frac{11.635}{5.3} = 2.196 \text{ in.}$$

Solving Equations [4] and [5] simultaneously:

$$m_1 + m_2 = 1.2$$

$$5.3^2m_1 + 2.196^2m_2 = 1.2 \times 11.635$$

$$m_2 = 0.848 \text{ lb.}$$

From Fig. 9, the acceleration of $m_2 = 0.778$ times the acceleration of the piston at any instant and lies in the same direction.

Similarly, for the central and outer rods $m_2 = 0.907$ lb. and 1.017 lb., respectively, and the corresponding accelerations of m_2 are 0.752 times and 0.697 times the acceleration of their pistons at any instant and lie in the same direction.

The Degasification of Boiler Feedwater

Fundamental Laws Governing the Separation of Dissolved Gases from Water by Air-Tension Control, and the Extent of Their Application to Conventional Types of Feedwater-Heating Equipment

By J. R. McDermet,[1] Jeannette, Pa.

Deäeration of the water fed to boilers and economizers for the prevention of corrosion is now a commercial realization. Engineering experience has also established empirically the degrees of degasification required, and indicated broadly the field in which it will be useful. One method among several which have met with success has been discussed from these relationships by the author in two previous papers,[2] and he proposes here to deal with the fundamental laws governing the operation of this method, and to indicate the extent of their application to conventional types of feedwater-heating equipment.

The method of degasifying water referred to above consists in first heating it to a temperature some 25 deg. fahr. above the temperature at which it is to be deäerated, this latter temperature being selected by reason of operating conditions. The heated water is then suddenly introduced into a chamber in which a vacuum is maintained by a condenser and an air exhauster in series. The vacuum is so correlated with the heater temperature that the water entering the deäerator chamber is superheated roughly 25 deg. above the temperature of the vacuum. This superheat energy produces a partial flashing into steam, and a pulverization of the liquid as it is suddenly injected. The steam, from the instantaneous boiling, enters the condenser, which is cooled by the supply water on its way to the heater. The heat liberated is recovered by the condenser and recirculated back to the heater. The non-condensable gases originally dissolved are removed from the end of the zone of condensation in the condenser by the air exhauster.

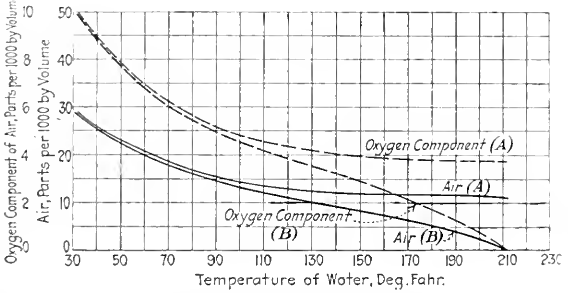

Fig. 1 Solubility Curves for Air in Water

[(A) Total pressure of air = 29.92 in. Hg.; (B) Partial pressure of air + pressure of water vapor = 29.92 in. Hg.]

The process is significant in that it involves no heat losses. A small quantity of heat, amounting roughly to 25 B.t.u. per lb. of water handled, is continuously recirculated between deäerator and heater, and any degradation of form which it suffers is not significant in heating processes. There are, however, energy charges in removing the water from the region of vacuum and in exhausting the non-condensable gases from the condenser.

The successful operation of this process depends upon three factors: (*a*) The inevitable reduction of solubility of dissolved gases in water with increase of temperature. This advantage is common to all forms of water-heating apparatus; (*b*) the explosive boiling caused by the rapid injection of heated water into a zone of lower boiling temperature. While only a very small amount of heat energy is involved, the rate of energy liberation is quite rapid, producing a boiling action, which is independent of diffusion currents within the liquid and results in a very effective disruption of the liquid; (*c*) a method of control and agitation of the water subsequent to the explosive boiling in a region of reduced air tension. This reduction of air tension is secured partly by the reduction of total pressure incident to the vacuum, and partly by the control of the boiling process to furnish a partial vapor component of total pressure to reduce the partial air tension, the sum of the two being equal to the pressure in the region of vacuum. Factors (*b*) and (*c*) in their application are unique with this apparatus, but the control of air tension is significant in any process of aeration or deäeration. This factor of air tension is the criterion by which to judge the performance of other types of feedwater-heating apparatus from the standpoint of the removal of dissolved gases.

The solution of gases from the atmosphere, eliminating carbon dioxide which goes into chemical combination, follows Henry's law. The principal gases in air—oxygen, which produces corrosion, and nitrogen, which furnishes the bulk of the volume—have different solubility constants, and it is expedient, therefore, to consider the application of Henry's law to the individual constituents. Henry's law is formulated by Nernst[1] thus: "Gases dissolve in any selected solvent in the direct ratio of their pressures." When applied to a gaseous mixture this law may be made more specific by saying that the solubility of any constituent is equal to a proportionality factor, which is different for each permanent gas and itself a function of the temperature multiplied by the partial pressure of the constituent. At any constant temperature the solubility of any constituent for purposes of engineering calculation varies directly as the partial pressure.

The solubility curves for air in water presented in Fig. 1 have been recomputed from the solubility data of Winkler. Two sets of curves are given, for both the oxygen component of air and for air, one set having been computed for a total pressure of air equal to 29.92 in. of mercury, and the other so that the sum of the partial pressure of the air and the pressure of the water vapor corresponding to the temperature will be 29.92 in. of mercury. Obviously, in the first case the total pressure is indeterminate without calculation, and in the second case the same is true of the partial air pressure. However, the two groups of curves are useful, for between their intercepted ordinates lie the solubility values of air in water for any open feedwater heater operating on raw water and under atmospheric pressure.

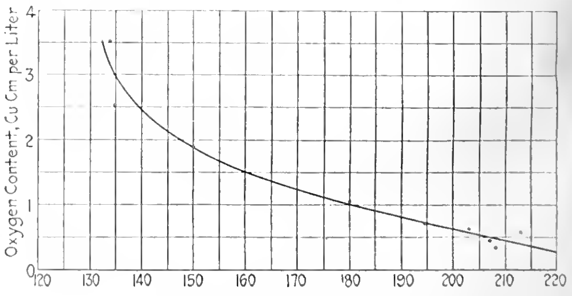

Fig. 2 Dissolved Oxygen in Water in Open-Type Feedwater Heater in Representative Central Stations

(Heaters fed with condensate from condensers.)

It is characteristic of an open-type feedwater heater that it operates under atmospheric pressure irrespective of the temperature to which it heats, and that the supplies of water and steam are not interrelated. As a result the control of partial air pressure in the heater depends primarily on the control of venting if the heater is

Presented at a meeting of the Baltimore Section of The American Society of Mechanical Engineers, Baltimore, Md., April 12, 1922.

[1] W. Nernst, Theoretical Chemistry.

operated at a temperature close to the atmospheric boiling point. Invariably, there is a high air tension and a very considerable saturation if the heater is operated appreciably below the boiling point. Fig. 2 gives the results obtained from various types of such heaters fed with condensate from surface condensers. The data plotted were collected in a general survey of representative central stations scattered over an area east of the Mississippi River and are indicative of the average performance.

One point on this curve, however, is taken from a thoroughfare heater operating at 208 deg. fahr. This heater was installed in a blast-furnace boiler plant, and the entire exhaust of the blowing engine was discharged through the heater. This corresponded to a more extravagant venting than is permissible in standard practice, but it indicates decisively the results a heater may give under proper reduction in partial air tension. All of the other heaters operate with the minimum amounts of venting consistent with temperature desired and in accordance with usual central-station practice.

The results to be expected from any standard heater operating with raw-water feed are illustrated in Fig. 3. One point is significant in this curve—that for an Elliott 1000-hp. open heater—and, in general, is applicable to all types of open heaters. There is a viscosity-surface tension relationship in water which prevents the liberation of air bubbles at temperatures below 160 deg. fahr. As a result, unless considerable precaution is taken, the air-removal results for heaters operating below this temperature are very erratic and sometimes represent no separation at all. As temperatures rise above 160 deg. the solubility values more closely approach the theoretical, but in any event the equilibrium of solubility between gases and water is obtained very slowly, and accordingly, heater results even within this range are sometimes disconcerting. It is possible, however, to calculate, as in Fig. 4, the minimum solubility to be expected from an open heater. This calculation is primarily a proposition in air tension. It is very difficult, if not impossible, however, to get a heater which will equal this performance on saturated supply water, and the curve, therefore, is only of suggestive significance.

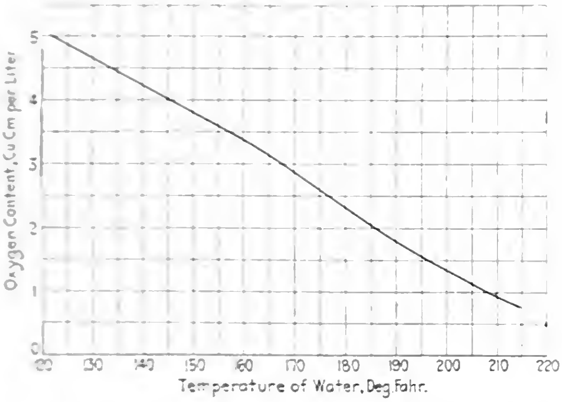

Fig. 3 Dissolved Oxygen in Water in Standard Heaters Operating with Raw-Water Feed

(Water saturated at 70 deg. fahr.)

The reason for the high values shown in the heater-performance curves is explainable from the curve of Fig. 5, which is plotted for vent mixtures from open feedwater heaters. It is an axiom in condensation work that the most efficient place for the removal of non-condensable gases is at the end of the zone of condensation. Unfortunately, there is no correlated control of steam and water in an open heater, and as a result no definite zone of condensation exists; it is therefore necessary to consider air removal on a pure vapor-mixture basis. As a result, in order to adequately remove a pound of air, it is necessary to remove a very significant amount of steam, even though the actual quantity of air involved is small. This curve rises so rapidly at 210 deg. as to make adequate venting almost prohibitive from a heat standpoint. It is primarily for this reason that open heaters do not adequately solve the deäeration problem.

A series of curves analogous to Fig. 5 but for a condenser heater of the jet type, are shown in Fig. 6. Since these heaters operate under vacuum and with different degrees of air exhaustion, the curves are plotted for different air tensions in the condenser body. The condition of control of steam and water exists under the same unfavorable circumstances as in the atmospheric heater, and air-removal conditions are extremely severe. Therefore, the three upper curves, for 0.2, 0.4 and 0.6 in. of mercury air tension, are of comparatively little significance, and the expense of pumping out the air mixtures has practically relegated the zone of operation to air tensions within the zone of the three lower curves, for 0.8, 1.0 and 1.2 in. of mercury air tension.

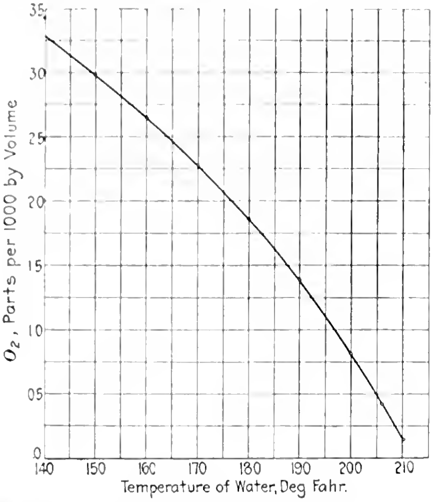

Fig. 4 Minimum Oxygen Saturation to be Expected with an Atmospheric Open Heater

In the open feedwater heater, venting is secured at the expense of steam only. In the jet-condenser heater, operating at vacuum, the vapor mixture must be mechanically exhausted. From a steam-ejector standpoint it requires practically as much energy to evacuate a pound of steam as it does a pound of air. Jet-condenser heaters have uniformly been more efficient äerators than deäerators, although their other merits are making their use extremely popular. In one installation, which perhaps may be said to represent the best from the standpoint of deäeration, the solubility of the water leaving the condenser is practically regulated by the condensate coming over from the main turbine condenser. In this case the jet condenser removes no air, but fortunately does not allow any to be added. It is also true that equilibrium between air and the solution of air in water is so slowly attained that spraying

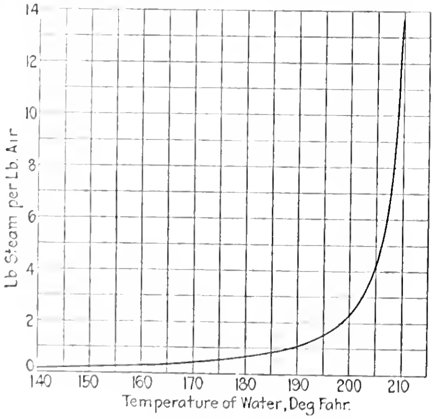

Fig. 5 Air-Steam Ratios in Venting Atmospheric Open Heaters

methods are uniformly unsuccessful in producing complete deäeration. There is, therefore, little probability that the jet-condenser heater, even with extravagant air-removal capacity, will offer a successful solution. It has, however, under the best conditions of heating, marked one step in advance, in that it has been found capable of preventing pollution of the water handled.

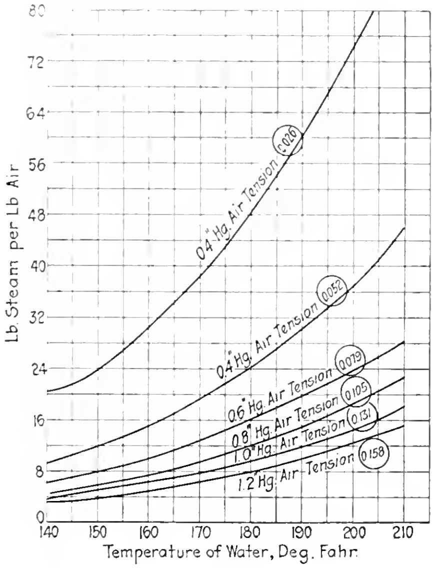

Fig. 6 Air-Steam Ratios in Removing Air from Jet-Condenser Heaters

(Figures in circles are mean solubility values in cubic centimeters per liter.)

The use of surface-condensing apparatus has two inherent disadvantages. While the condensate or water which is to be heated does not come in contact with air, the use of such apparatus for exhaust steam from small turbines under modern boiler conditions is limited by the conductivity of superheated steam. The exhaust from small auxiliaries is so high in superheat under high boiler pressure and high boiler superheat that it is almost impossible to secure a workable conductivity without desuperheating. Where desuperheaters are employed or steam is extracted from an intermediate stage of the main unit within the saturated zone, the problem is complicated by the äeration of the condensate in the heater.

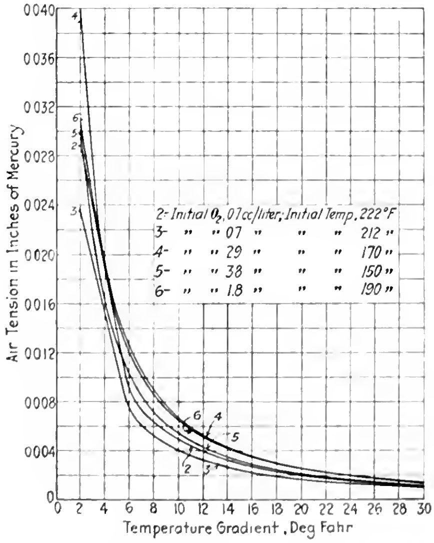

Fig. 7 Characteristic Curves of DeÄreator Described in Text

Fig. 7 indicates the analogous condition of control of air tension in the deäeration process previously described. The scale of ordinates for these curves is inches of mercury air tension, and the scale of abscissas the B.t.u. drop in the instantaneous boiling. The various curves range between the maximum and minimum operating temperatures employed in the process and for initial air contents which ordinarily accompany these temperatures in feedwater heaters of the open type. Obviously, the closed type merely retains the air content of the water entering it. It is a fortuitous circumstance that the natural coördination between normal air contents in heating apparatus and vacuum are such that these curves even for widely different conditions are approximately parallel and lie within the same zone. The minimum air tensions in the operating range amounting to less than 0.002 in. of mercury, indicate very forcibly the reason for the effective results which are secured by this process. However, the results which are theoretically obtainable are decidedly lower than the results actually obtained. The water is handled in the region of vacuum by agitating pans, which as a general premise are very much more effective than any type of spray nozzle. These curves are not in any sense an exposition of the complete operation of the deäeration process under consideration, but they do explain very satisfactorily and very accurately the underlying principles upon which successful operation is based, and indicate in radically new ways the relation of these principles to other features of power-plant apparatus.

Some mention was made in an earlier paragraph of the fact that a gradient of 25 deg. was employed between the heater and the deäerator. For all conditions of pressure the characteristic curves become practically parallel to the axis of abscissas in the neighborhood of 25 deg. There is no appreciable gain from increasing this value and it is economically wrong to extend the range of temperature gradient unless it be for some purpose of regulation as a part of a complete power plant. It is true, however, that the process does not operate efficiently at heater temperatures below 160 deg. fahr., and in case it is desired to go to operating temperatures on the deäerator as low as 130 deg. fahr., the temperature range must be extended beyond 25 deg., regardless of economic proportioning.

Vanadium metal is a silver-white lustrous metal with an atomic weight of 51.2 and a specific gravity of 5.5. It owes its great economic value to the fact that when added to steels in quantities ranging from 0.05 per cent to 0.50 per cent, it removes occluded oxygen and nitrogen, and combines with the steel to the very great improvement of its physical properties. In the smaller proportions, it confers great toughness to steel, making it particularly well adapted for automobile axles and other parts subject to excessive stress. In larger proportions it is used in high-speed and other tool steels to which it imparts certain desirable qualities which no other known substance can give in an equal degree. This fact has led to its becoming a standard constituent of such steels. Nearly all the vanadium in such steels is found in the pearlite as a combined carbide of vanadium, iron and any other metals present.

In English high-speed tool steels, the vanadium proportion is usually from 1 per cent to 1.5 per cent. Prior to the war, high-speed steels contained carbon, chromium, tungsten, and vanadium in varying proportions but the vanadium proportion was not more than 1.5 per cent. While these steels were excellent materials for high-speed tools, very much better steels have since been discovered, practically all of which contain vanadium. An interesting development has been the subject of a British patent in which the inventor claims that 18 per cent of tungsten can be replaced with advantage by 6 per cent of molybdenum in the presence of a little over 1 per cent of vanadium. In these steels vanadium is regarded as the key element, and its functions are described as stabilizing the variable properties of molybdenum steel and the prevention of cracking during the water-hardening operation. The result is said to be not only a steel of remarkable hardness but also thermal stability. Moreover, it is claimed that this molybdenum-vanadium steel does not "let down" until a heat of 700 deg. cent. is reached, in which respect it is superior to most other steels of this class.—*Engineering* (London), Aug. 4, 1922, p. 151.

An Investigation of the Herschel Type of Weir

Results of Tests Made to Determine the Effect of Various Modifications in Construction on the Action of the Improved Type of Weir Designed by Clemens Herschel for Gaging in Open Channels

By RICHARD H. MORRIS,[1] HARRISON, N. J., AND ALBERT J. R. HOUSTON,[2] BOSTON, MASS.

THE great multiplicity of weir types and the corresponding multiplicity of weir formulas early led Mr. Clemens Herschel to believe that the problem of measuring large quantities of water was being attacked from the wrong angle. As early as 1888, in an article in *Engineering News* for November 10 of that year, he protested against the usual method of making weir observations and suggested that the measurements be taken at the crest. When The American Society of Mechanical Engineers appointed a committee to draft a revised form of Power Test Code in 1917, Mr. Herschel was made a member and the Engineering Foundation made an appropriation to be expended by him in research work on weirs. In September, 1919, in the Hydraulic Laboratory of the Massachusetts Institute of Technology, he built and tested a weir which he briefly described in an article entitled An Improved Weir for Gaging in Open Channels, as follows:

> The fundamental idea followed in the design of the new weir was to have the water to be measured conducted over the weir in a gentle manner, and so as to have it flow smoothly and regularly from the time it first encounters the weir construction until it leaves it. Instead of allowing the body of water to impinge with more or less violence, according to the velocity with which it approaches the weir, against a perpendicular wall in its path (the upstream face of the ordinary weir), it is gently led to the crest by a 2:1 slope. Instead of striking on or being torn over a sharp edge at the crest, the crest is made in the form of an arc of a circle; and instead of bothering about air under the nappe, the nappe is supported on another 2:1 slope downstream from the crest. Moreover, the crest is made hollow so that observations of the pressure or lack of full pressure, whichever the water may elect to exercise, can be taken at the crest, not at a distance upstream from the crest at a distance varying according to the fancy of the experimenter.
>
> If the quantity passing over the weir turn out to be a function of this observed pressure, well and good. If not, we will see what virtue there is in the difference of water elevations or pressures, the one taken upstream from the weir and the other taken by means of the hollow weir crest.

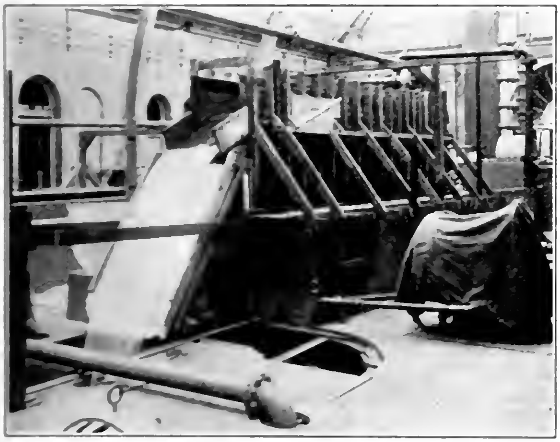

FIG. 1 HERSCHEL-TYPE WEIR AS ARRANGED FOR TESTING

> The difference referred to above proved to be the sought-for solution of the problem at hand...... A United States patent has been applied for covering the weir construction herein described.
>
> Our weir crest had a radius of 0.198 ft., and the outside surface was hard and smooth oil paint.

The results of this test were presented to The American Society of Mechanical Engineers at their Spring Meeting in May, 1920, an abstract of the paper having been published in MECHANICAL ENGINEERING for February of the same year. Mr. Herschel's tests showed that for discharges of from 0 to 9.55 cu. ft. per sec. per ft. of weir length (the limits covered by the experiments) the quantity of water flowing, Q, was directly proportional to the difference, d, in two pressures, one measured just upstream from the weir, and the other measured at the crest, the formula being $Q = 5.50\ d$.

NATURE OF THE INVESTIGATION UNDERTAKEN

The work herein described constitutes an investigation of a Herschel-type weir from six distinct points of view. First, an attempt was made to check the work of Mr. Herschel. Next, it was desired to find the effect on the action of the weir of the following five modifications in its construction:

1 The degree of smoothness of the crest and slopes
2 The radius of the crest
3 The position at which the upstream measurement is made

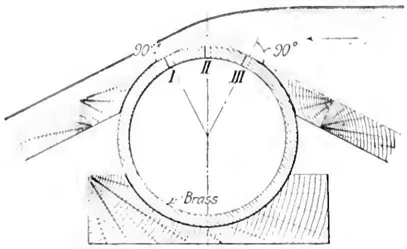

FIG. 2 DETAIL OF CREST OF HERSCHEL-TYPE WEIR

4 Increasing or decreasing the velocity of approach
5 Changing the position of the orifices in the crest.

Undeniably, the work should have included an investigation of the effect of different slopes. However, neither time nor funds were available for such extensive work as this would require.

DEFINITIONS OF TERMS

Throughout this paper whenever any of the following terms are used their meaning will be covered by the definitions here given.

Crest: The brass tube set at the juncture of the two slopes, forming a smooth, slightly curved surface over which the water flows.

Weir Length: The length of the crest at right angles to the direction of flow.

Velocity of Approach: The mean forward velocity of the water in the section of the weir box at the foot of the upstream slope, computed by the formula $V = Q/A$.

Sharp-Crested Weir: The ordinary type of weir in which the crest and sides are made of a thin slab of metal so constructed that the nappe or overfalling water touches only the sharp upstream corner or edge of the crest.

THE APPARATUS USED

The tests to be described were performed in the Hydraulic Laboratory of the University of California. Among other things this laboratory is equipped with six electrically driven centrifugal pumps, two calibrated measuring tanks, and two storage tanks. A sharp-crested weir is arranged to overflow into one of the calibrated tanks. The Herschel-type weir to be tested was built on top of the sharp-crested weir. All six of the pumps were arranged to discharge into the new weir. From it the water ran into one of the calibrated tanks, which in turn overflowed into the other calibrated tank. By means of a sliding gate the water could be diverted from the calibrated tanks into one of the storage tanks without stopping the pumps. The combined capacity of the six

Abridgment of paper awarded the A.S.M.E. Student Prize for 1921.

pumps was approximately seven and one-half cubic feet of water per second.

In external appearances, as shown in Fig. 1, the new weir very much resembles a long, narrow box with its sides braced on the outside. The box was 17$^{1}/_{2}$ ft. long, 5 ft. high, and a little over 2 ft. wide. The crest was 2.0335 ft. long and was made of a brass pipe with a line of $^{1}/_{8}$-in. holes along its length, spaced 1 in. apart. Two different sizes of pipe were tried, one being a standard 4-in. pipe and the other about 2 in. in diameter. The actual external radii of these pipes were 0.1878 ft. and 0.0792 ft., respectively. The crest was placed 3 ft. above the floor of the weir. The approach to and from the crest had a slope of 2:1, that is, 1 ft. rise for each 2 ft. horizontal distance. The whole construction, except the pipe, was of wood, the supporting timbers being 4 in. by 4 in., the braces 2 in. by 4 in., and the sides, floor and slope $^{7}/_{8}$-in. tongued and grooved flooring. The weir was fitted with three orifices for measuring the upstream pressure. These were flush with the side, $^{3}/_{4}$ ft. below the level of the crest, and respectively 6 ft., 7$^{1}/_{4}$ ft., and 8$^{1}/_{2}$ ft. upstream from the crest. From these orifices rubber tubing led to a water manometer constructed on an angle as is the conventional draft gage. The angle at which the manometer was set was such that 3 ft. along the slope corresponded to 1 ft. rise vertically. It was calibrated by comparison with a vertical gage. The pressure from the crest was also led to this same manometer, where suitably arranged valves made it possible to read the pressure at any of the three orifices or the crest. Baffle plates were used to steady the flow.

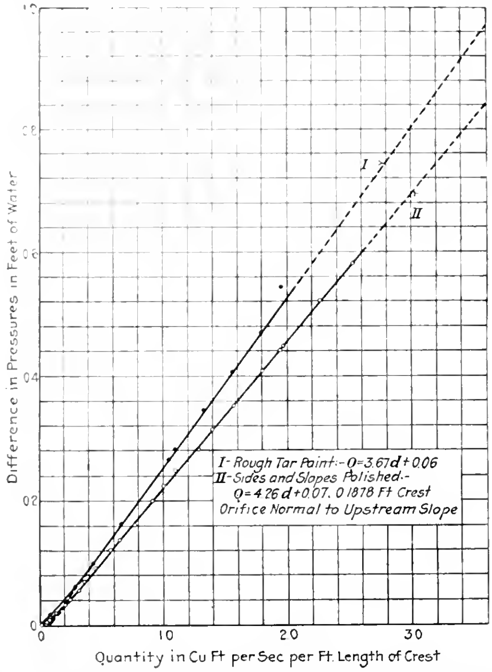

Fig. 3 Effect of Roughness of Surfaces on Discharge of Herschel-Type Weir

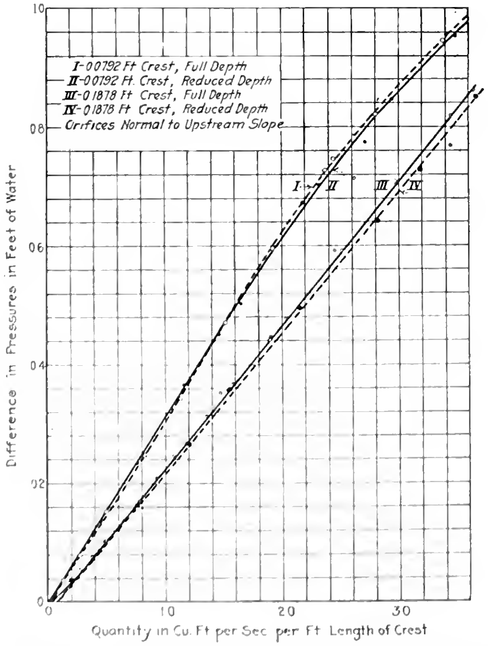

Fig. 4 Effect of Radius of Crest and Velocity of Approach on a Herschel-type Weir

In order to increase the velocity of approach a raised floor or false bottom was sometimes set in the weir. It was 2 ft. above the original floor and terminated 9$^{1}/_{2}$ ft. upstream from the crest in a 1:1 slope.

Laboratory Procedure

At first the 4-in. pipe was fitted with the $^{1}/_{8}$-in. orifices at right angles or normal to the upstream slope (position III, Fig. 2). A preliminary test of ten runs was made with the sides and slopes covered with rough asphaltum paint. The small cracks between the wooden slopes and the brass pipe were left open.

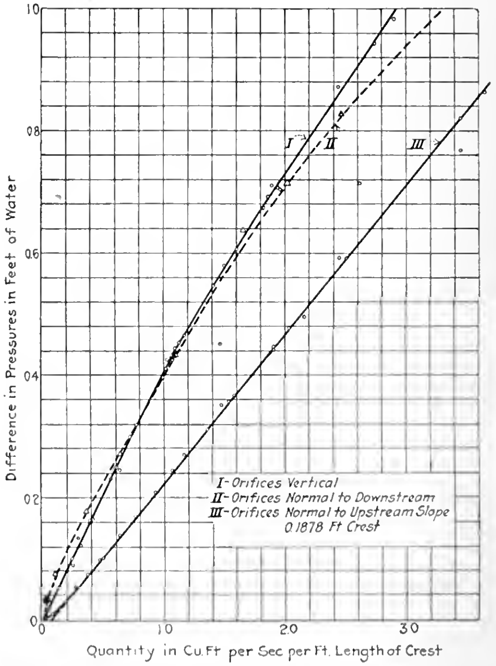

Fig. 5 Effect of Position of Orifices in a Herschel-Type Weir

These cracks were then filled and smoothed with modeling clay and the sides and slopes were scraped, oiled and polished. Another test of twenty-three runs was then made.

After completion of these tests the orifices in the crest were changed to the vertical position (II) and thirty-five more runs taken. A test of thirteen runs was then taken with the orifices at right angles to the downstream slope (position I, Fig. 2). It was found that pressure conditions were too unsteady with the orifices in positions I and II, so they were changed back to position III and a further test of twenty-five runs was then made. The

velocity of approach was next increased by fitting in the weir the raised floor and nine runs made.

With this raised floor still in place, the large pipe in the crest was replaced by the small one and the orifices set at right angles to the upstream slope. A test of ten runs was made with these conditions. The raised floor was then removed and eleven runs made.

The work of constructing the weir was begun on June 3, 1920, the first run was made on the 28th of the same month, and the last run was finished on July 23. The data obtained in the tests are given in an appendix to the complete paper.

The typical procedure in taking a run was as follows: The sliding gate was set so as to divert the stream of water into one of the storage tanks. Whatever pumps it was desired to use were then started and the throttle valves regulated to give the desired reading on the differential gage. The hook gages on the measuring tanks were then read. After the flow became steady the sliding gate was pushed under the stream so as to allow it to flow into the measuring tanks. The stop watch was started just as the gate moved under the stream. Readings were taken on the differential gage of the pressure both at the crest and at each of the three upstream orifices. Usually there was time to take several sets of readings and the mean of each was used in calculating the results. When the tanks were sufficiently full the sliding gate was pulled back into its first position so as to again divert the water into the storage tank, and the watch was stopped. Hook-gage readings were then taken of the water level in the measuring tanks.

It was found that if this weir was treated as an ordinary broadcrested weir of irregular section and the quantity discharged plotted on logarithmic coördinate paper against the upstream reading, the result was a very good straight line. Therefore the measuring tanks were not always used, but instead sometimes the quantity discharged was read off this logarithmic calibration curve.

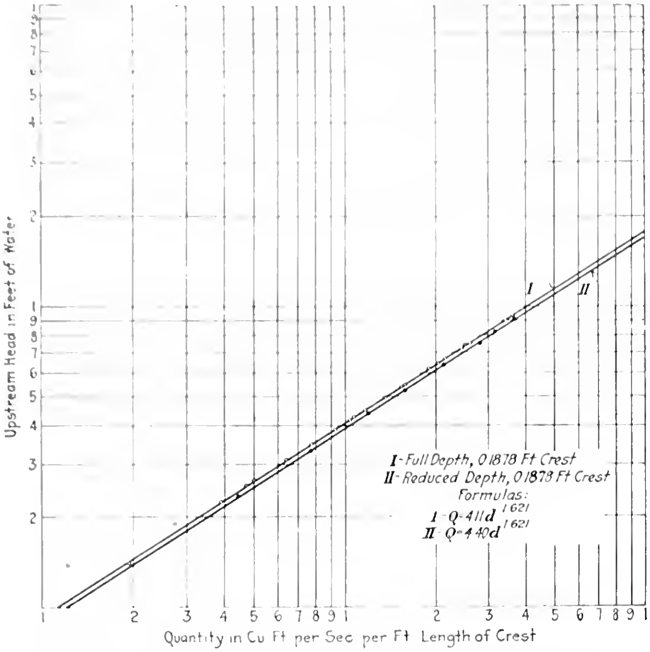

Fig. 7 Effect of Velocity of Approach on a Herschel-Type Weir
(For 0.0792 ft. crest, Q(full depth) = $4.3d^{1.621}$; Q(reduced depth) = $4.5d^{1.623}$.)

Calculation of Results

Curves were plotted of head due to velocity against quantity for both the full depth and the raised floor. It was then unnecessary to figure out the velocity head for each run. Instead it was merely read off the curve from the corresponding quantity. The following is a sample of the computations made for the full-depth curve:

$$\text{Quantity} = \text{Area} \times \text{Velocity, or } V = Q/A$$
$$\text{Velocity Head} = h_v = V^2/2g$$

where g is the gravitational constant. Q is measured in cubic feet per second per foot of length of crest. Then the area per foot of length of crest equals the height of the crest above the bottom of the weir plus the observed measured head upstream.

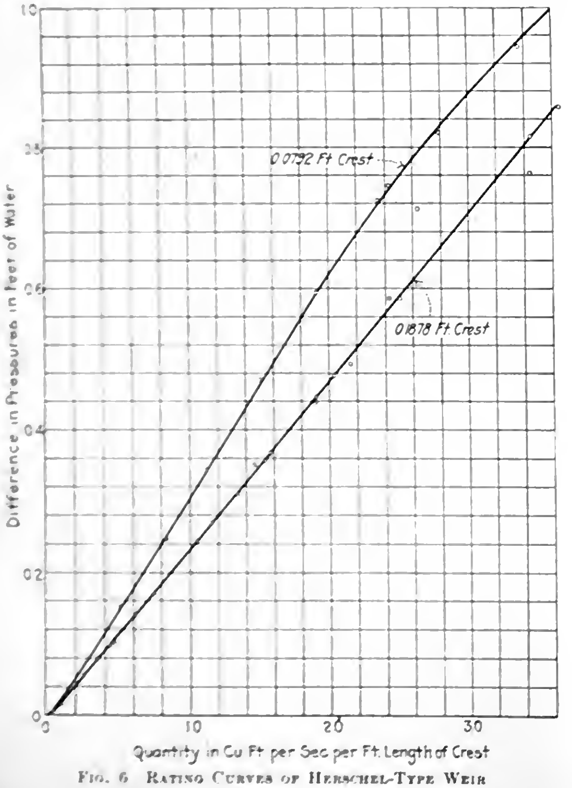

Fig. 6 Rating Curves of Herschel-Type Weir

From the logarithmic calibration curve of the weir with full depth a quantity of 3.00 cu. ft. per sec. per ft. of length of crest corresponds to an upstream head of 0.810 ft. The crest is 3.015 ft. above the floor. Therefore the area per foot of length of crest is 3.015 + 0.810 = 3.825 sq. ft. Then—

$$V = Q/A = 3.00/3.825 = 0.785 \text{ ft. per sec.}$$
$$h_v = V^2/2g = (0.785)^2/2g = 0.615/64.36 = 0.00956 \text{ ft.}$$

Summary of Results

In plotting the accompanying curves from the data obtained the two following rules were always used: (1) $V^2/2g$ was always added to the difference between the crest and upstream pressures. (2) When a curve did not pass through the origin on rectangular coördinate paper, the value of the quantity where the curve cut the line of zero difference was subtracted from each quantity when plotted on logarithmic paper, giving an equation of the form $(Q-K) = Cd^n$.

From an examination of the curves it is evident that all the factors mentioned earlier in the paper affect the discharge to some extent. The discharge constant varies over a wide range, depending upon the existing conditions.

Friction greatly affects the discharge of this type of weir and, as is shown in Fig. 3, this variation may be as great as 12 per cent. This is a disadvantage and will have a bearing upon the change of slope, the effect being proportional to some function of the velocity—probably the square. Friction and contraction are the two limiting factors of the discharge, and from Bazin's experiments it seems that a 2:1 slope represents the point where the combined effect is about a minimum and the discharge a maximum. In order to offer a basis of comparison, it would be well if future experi-

menters would do their work with surfaces that are capable of fairly accurate reproduction, such as cement, hardwood flooring or germanstone.

Figs. 4, 6 and 8 indicate that the formula for the discharge is materially affected by the size of the pipe forming the crest. This may be explained in several ways. Generally speaking, by decreasing the radius of the crest a sharp-crested weir is approached, and the smoothness of flow is thereby altered. Thus the size of the crest affects the contraction and consequently the actual discharge. On the other hand, it will be seen that the size of the crest affects the crest gage reading and therefore the formula for the weir. For, since the holes are normal to the upstream slope, the size of the crest determines the distance from the top of the crest to the orifices. Therefore the size of the crest will vary the component of the velocity that enters the orifices. It is not known, however, whether these two effects tend to increase or oppose each other.

The particular curves (Figs. 6 and 8) of the small crest seem to indicate that each size of crest has definite limits between which the discharge varies as a straight-line function.

Upstream measurements taken with three gages were identical below about $3^1/_2$ cu. ft. per sec. per ft. length of crest. Above that quantity the gage nearest the crest showed a slight drop, indicating that the upper-surface curve extended at least 6 ft. upstream from the crest.

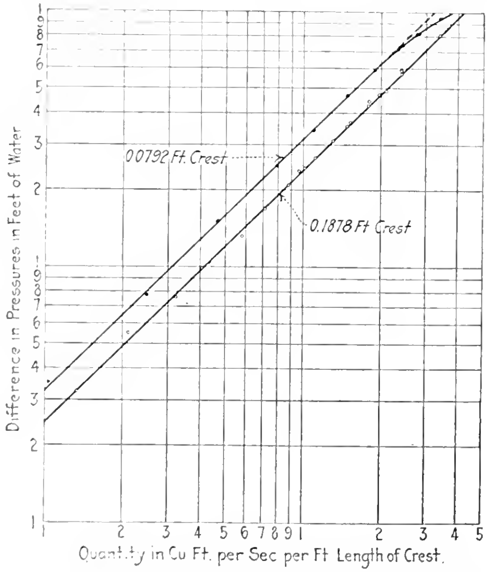

Fig. 8 Logarithmic Rating Curves of a Herschel-Type Weir
(For 0.1878 ft. crest, $Q = 4.16d + 0.07$.)

That the velocity of approach cannot be corrected for by means of the simple formula $V^2/2g$ is shown in Figs. 4 and 7. The velocity of approach was increased nearly 300 per cent, with a corresponding difference of about 7 per cent in the corrected discharge curves. The weir is therefore similar to a sharp-crested weir in this respect, because both Bazin and Francis specify that the height of the crest above the floor of the weir box must fall within certain limits if their formulas are to be applicable.

The most important factor is the position of the orifices in the crest as shown by Fig. 5. The discharge is a straight line-function only when the holes are normal to the upstream slope, or nearly so. The constant may be varied almost at will by rotating the orifices with respect to the horizontal axis of the crest. It is doubtful, however, if the constant 5.50 as obtained by Mr. Herschel could have been obtained with the weir used in these experiments, due to the difference of about 0.01 ft. in the crest radii.

Conclusion

The results of this investigation tend to show that when a weir of the Herschel type is properly constructed there is a constant ratio between the quantity of water passing over the weir and the difference in the two observed pressures. However, so many are the determinant factors and so great is their influence upon the discharge formula that a weir of this type, in its present state of development, would probably be valueless unless calibrated by actual tests. It is believed that further extended research may remedy this difficulty. Probably the chief advantage of the new weir lies in the fact that for the same upstream head it discharges about 20 per cent more water than the ordinary type of weir.

FORCES IN ROTARY MOTORS

(Continued from page 647)

Table 5 gives the accelerations and inertia forces of these equivalent masses for every 10 deg. rotation of the motor.

Plotting the net component piston force acting up the connecting rod for every 10 deg. rotation of the motor, and drawing its moment arm, the turning effort of the net piston force is calculated, the results for 20-deg. intervals being presented in Table 6. The maximum turning effort from this source for one piston is 27.7 ft-lb. and occurs when the cylinder is 30 deg. off dead center at the beginning of the stroke.

In Fig. 10 the direction of the equivalent inertia force of the connecting rods, for every 10 deg. rotation of the motor, is plotted and the moment arm shown. From this diagram the turning effort of the connecting rods is calculated and the results are given in Table 7. The turning effort is positive up to 180 deg. and negative from 180 to 360 deg. These positive and negative turning efforts exactly balance each other, the maximum occurring 60 deg. off dead center and amounting to about 12.5 ft-lb. per connecting rod.

Table 8 gives the turning effort due to the compound supplementary inertia force of the piston, $2U\omega m$ (heretofore neglected in similar calculations); which amounts to almost fifteen times that of the net piston force, and over thirty times that due to the inertia of the connecting rods. This is also positive up to 180 deg. and negative from 180 to 360 deg., the negative balancing the positive.

Fig. 11 shows a representative portion of the final turning-effort diagram of the LeRhone 80-hp. motor. The dotted lines represent the turning effort due to the inertia of the connecting rods; the dot-and-dash lines the turning effort due to the net piston pressure; the dash lines the turning effort due to the compound supplementary inertia of the piston; while the heavy lines represent the combined turning efforts. The inertia forces balance, and the final turning effort depends only upon the net piston pressure.

The "heat pump" is an apparatus working on a reversed heat-engine cycle, the object of which is to economize heat in evaporating processes, such as the concentration or the distillation of liquids.

In the heat-pump process the vapor from the evaporator is taken to a compressor, in which its pressure, and hence also its temperature, are raised to such a degree that the compressed vapor may serve as the heating medium in the evaporator. It is returned to the heating element of the evaporator accordingly, where it is used for the evaporation of a further amount of liquid.

While in certain circumstances a small quantity of live steam may have to be supplied, in general the only energy required in order to carry on the process is that necessary to drive the compressor. The efficiency of the process from the thermal or energy point of view may therefore be measured by comparing the evaporative effect produced with the power expended in driving the compressor. This power may be derived from fuel consumed in the power unit or station from which the compressor is driven, or, of course, from any other source of power, such as water power, and involve no expenditure of fuel at all. Also the compressor may be driven directly by the prime mover or the drive may be indirect, the transmission being effected electrically. The compressor may also take the form of a jet pump supplied from an external source with steam which mixes with the vapor from the evaporator, and is delivered with it to the heating element. The variations of the process are numerous, but all are characterized by the fact that the vapor produced is compressed and returned to the evaporator as the heating medium. T. B. Morley in *The Engineer* (London), July 14, 1922, p. 27.

The Fuel Problems of the Pacific Coast

The Future Fuel Supply of California—Reasons Why the Railways and Merchant Marine Should Receive Preferential Treatment in Case Oil-Fuel Conservation Becomes Necessary

AT A MEETING of the San Francisco Local Section of the A.S.M.E., held February 23, 1922, three papers were presented dealing with the conservation of the present fuel supply of the Pacific Coast and the development of new sources. Reasons were given why the railways and merchant marine of the Pacific Coast should not be affected by any restrictions in the use of fuel oil which the diminishing supply might make necessary. Abridgments of these three papers follow, together with the introduction to the discussion given by F. H. Sibley, dean of the College of Engineering, University of Nevada.

THE FUTURE FUEL SUPPLY OF CALIFORNIA

By C. H. DELANY,[1] SAN FRANCISCO, CAL.

IT IS the purpose of this paper to point out certain facts in connection with the future fuel supply of California which appear to be of importance in view of the possible decrease in available supply of California oil.

A recent joint survey, made by the United States Geological Survey and the American Association of Petroleum Geologists, estimates that the quantity of oil recoverable by present methods remaining in the ground in California on January 1, 1922, including known and probable fields, amounts to 1,850,000,000 bbl. For some years the production of oil in California has been in excess of 100,000,000 bbl. per year, so that it appears that if the present rate of production could be continued, the oil supply would be exhausted in less than twenty years. The estimate represents the best judgment of the geologists, but unknown fields may be discovered in the future, so that it is impossible to predict with any degree of certainty how long the oil supply will last.

While it is true the development of new oil fields in the state may increase the total supply of oil, it is also probable the development of methods of oil refining will in the future use more and more of the oil for gasoline and other valuable products and leave less and less for fuel purposes. It is also probable that the many advantages of oil for marine purposes will tend sooner or later to cut off the supply for many uses for which fuel is required on land. It therefore seems appropriate at this time to discuss the situation in which we will some day find ourselves when our present fuel supply is cut off.

The production of California oil, as shown by the records of the State Mining Bureau, has increased from 4,329,950 bbl. in 1900 to 114,800,000 bbl. in 1921. About 8 per cent of this is used as fuel in the oil industry itself, and over 80 per cent of the remainder is distributed as fuel to the industries of California and other states.

Table 1 shows the purposes for which oil was used as fuel in California during the year 1917. It is seen from this table that in that year the quantity of oil used as fuel in California amounted to 4,467,000 bbl. per month, or at the rate of 53,604,000 bbl. per year. On the basis of 3$^1/_2$ bbl. of oil to one ton of coal, this quantity of oil is equivalent to 15,300,000 tons of coal. In addition there were used in 1917 in California over 700,000 tons of coal, bringing the total annual fuel requirements of the state up to an equivalent of 16,000,000 tons of coal. The population of California in 1917 was somewhat over 3,000,000, so the fuel requirements amount to about 5 tons of coal per capita. This compares with an average coal consumption throughout the United States for the year 1920 of 5.7 tons per capita. It is evident, therefore, that if the growth of California is to continue at the present rate, producing a population of 10,000,000 by 1950, and if the supply of California oil is cut off, we shall require by that time for fuel purposes the equivalent of 50,000,000 tons of coal per year.

TABLE 1 FUEL OIL USED IN CALIFORNIA
(Crude and residuum)

	Bbl. per Month	Per Cent
Railways	1,956,000	43.8
Steamships	555,000	12.4
Public utilities	555,000	14.7
Mining and smelting	52,000	1.2
Industries	483,000	10.8
Lime and cement	158,000	3.5
Sugar refining	103,000	2.3
Agriculture	73,000	1.6
Heating buildings	150,000	3.4
Miscellaneous	282,000	5.3
Total	4,467,000	100.0

Hand in hand with the development of the oil industry has gone the development of the hydroelectric-power industry, which is of course also responsible in a large part for the development and growth of California during the last twenty years. There is an impression among many that hydroelectric power will serve as a substitute for fuel and that when our oil supply has been used up we shall simply have to turn to the "white coal" of the Sierra Nevada Mountains.

There are many industries, however, that cannot do without fuel of some form, regardless of the quantity of electric power available. Of the 655,000 bbl. of oil used per month by public utilities, probably at least one-half was used for the manufacture of gas. Gas is a direct product of the oil itself, and if oil is no longer available some other fuel must be substituted for it. Lime and cement works used 158,000 bbl. per month. Electric power is already used extensively in these industries for operating the machinery, but fuel of some sort must be used in the kilns themselves. Heating by electricity is a possibility, but electric energy is of far greater value for the production of power than for the production of heat, and it is certain that the heating of buildings and industries requiring heat such as fruit canning, sugar refining, etc., will continue to demand an adequate supply of fuel.

Even if it were practicable to substitute electric power for all of the industries which are now using fuel oil, it must be borne in mind that there is a limit to the quantity of hydroelectric power available. It has been estimated that at the present rate of growth of the hydroelectric-power industries, the economic limit of hydroelectric development in the State of California will be reached in the year 1941. This limit, of course, will be reached all the sooner if hydroelectric power is substituted for fuel oil wherever practicable, such as by electrifying the railroads and the greater use of electric power in industry.

The question, therefore, is what kind of fuel is to be used after the California oil is exhausted, and where it is to come from? At first thought it would appear that fuel oil may be imported from other countries. However, on investigation we find that the petroleum supply of the whole world is quite questionable and cannot be depended upon to last more than 20 or 30 years, and as California would be in competition with the rest of the world in its use, we cannot count on a supply of imported oil that would meet our requirements. Natural gas is available in certain sections of California, but its use is only local in these particular sections, and it cannot be considered as a fuel supply for the whole state; moreover it is probable that the natural-gas supply will be exhausted sooner than the oil supply.

We must therefore turn to coal as the only reliable fuel for the future, and the problem accordingly becomes a question of where can we obtain our required supply of coal at the least expense and in a manner best suited to our own development.

A very complete survey of the coal resources of the world was made by the International Geological Congress held in Canada in 1913. From this report the information in Table 2 has been selected, applying to the Pacific Coast and neighboring states.

California coal is low-grade lignite, running from 9,000 to 12,000 B.t.u. per lb. Owing to the small quantity available it need not be given serious consideration as a substitute for fuel oil.

Oregon has a considerable supply of coal in Coos Bay region, much of which has been sent to California in former years, although

---

[1] Pacific Gas & Elec. Co. Mem. Am.Soc.M.E.

the output from the Oregon mines has always been small. Oregon coal is a very low-grade lignite, high in ash and moisture and running from 7,000 to 10,000 B.t.u. Owing to its low grade it would not be a satisfactory source of supply of fuel for power purposes although it has met with favor when used for domestic purposes.

The state of Washington has available large quantities of coal of a variety of grades. Bituminous coal is mined extensively and is of fair quality. Large deposits are found to the west of the Cascade Mountains, within 50 miles of Puget Sound, so that shipment by water to San Francisco and other California ports can be readily effected Sub-bituminous coal or lignite, is found extensively within a few miles of Puget Sound, but this coal is of very low grade, contains a large amount of moisture and volatile matter, and disintegrates when exposed to the air so that it cannot be transported without losing much of its heating value.

TABLE 2 COAL RESOURCES OF PACIFIC-COAST AND NEIGHBORING STATES

	Area, Sq. Miles		Estimate of Original Amount of Coal in Million Metric Tons	
	Known coal fields	Possible coal fields	Low-grade lignite or sub-bituminous	Fair-grade bituminous
California	10	30	15	25
Oregon	90	140	907	....
Washington	1800	....	47588	10355
Idaho	230	1000	90	544
Nevada	....	....	....	....
Utah	3646	....	141	3630
Arizona	3610	....	12832	9
New Mexico	13220	....	156903	17173

Nearly 80 per cent of the coal now used in California comes from Utah, which state has a large supply of a fairly good grade of bituminous coal running from 12,500 to 13,000 B.t.u. per lb. However, owing to the distance and the high freight rate for rail transportation, amounting at present to over $7 per ton, this can never be a cheap coal on the Pacific Coast. In 1918 the total quantity of coal consumed in California amounted to 830,368 tons, of which 653,766 tons or nearly 80 per cent came from Utah.

New Mexico has abundant reserves of coal. Some of this coal now finds its way into California, but as it is a poorer grade than the Utah coal and must absorb as high a freight rate, it is not likely to become a serious factor in the fuel supply for California.

Practically no coal is now mined in Arizona, Nevada or Idaho. The coal fields of Arizona are located in the eastern part of the state and are at present inaccessible. The coal is of poor quality, having ash content in some cases as high as 50 per cent, and while it may eventually prove of value for local use it is not worth shipping to the coast. Nevada has only one known coal field, of small extent located in the central part of the state. Idaho contains three known coal fields, but the seams are thin, the coal is of an inferior quality and little development work has been done.

The most promising supply of high-grade coal for the Pacific Coast is in the territory of Alaska. The Pacific Coast section, which is in the southern part of the territory bordering on the Gulf of Alaska, contains 458 square miles of known coal fields and over 8000 square miles of possible coal fields. The coal available is of all characters, from low-grade lignite to the highest grade semi-bituminous and anthracite. An estimate of the quantity available is given in Table 3.

TABLE 3 COAL AVAILABLE IN THE PACIFIC COAST SECTION OF ALASKA

	Estimated amount of coal, million metric tons
Lignite	1971
Sub-bituminous	485
Bituminous	2
Semi-bituminous	1293
Anthracite	1931
Total	5682

The best grade of coal for steaming purposes is found in the Matanuska field, which is not far from the coast and through which the recently completed Government railroad passes. No coal has as yet been exported from Alaska, but it is probable that this will eventually become one of the main sources of coal for the Pacific Coast, especially for such purposes as require the higher grades of coal.

Turning now to the possibility of importing coal from foreign countries, we find that the nearest foreign coal available is that on Vancouver Island. Much of this coal has been imported into California in the past from the well-known Wellington Mine. This is a fair grade of bituminous coal running from 12,500 to 13,000 B.t.u. The quantity of coal available is estimated at 5,191,000,000 tons. Large reserves of coal are also found on the mainland of British Columbia.

Turning to South America, we find a good grade of bituminous coal located in Chile. This coal is near the coast and could readily be shipped. There is also in Chile some anthracite coal of excellent quality. The quantity of coal available is estimated at 2,000,000,000 tons. The best coal is found in the neighborhood of Santa Maria Island and contains only 4 or 5 per cent of moisture and from 2 to 11 per cent of ash. It burns with a long, smoky flame and contains over 13,000 B.t.u. per lb.

In Peru there is also an abundant supply of coal, although very little is mined at the present time. The reserve is estimated at 1000 million tons of commercial coal.

With the present development of commerce with the countries so far considered, if large importations of coal were made there would be no return cargo for the ships carrying it. In other words, unless commerce can be developed to such a point as to bring about a considerable export trade from California to Chile or Alaska, as the case may be, the cost of transportation of coal would be doubled by the necessity of sending the ships back in ballast. It is thus evident that the question of future coal supply for California is intimately associated with the development of California's export trade. This leads us to consider the possibility of importing coal from countries at greater distance, with which trade is most likely to develop. Previous to the development of the California oil industry coal was imported from Australia, Japan, England, Wales and Scotland, as well as from British Columbia.

Some of the world's greatest coal deposits are found in China. It is estimated that China contains 999,000 million tons of high-grade coal, amounting to about one-fifth of the world's total supply. Half of the coal supply is supposed to be anthracite. Some of the coal fields are located fairly near the coast, so that with the cheap labor available in China for mining it would be possible to ship the coal at a low price.

To sum up, while the exhaustion of our oil fields will deprive us of a native fuel, there is no cause for alarm. Domestic coal can be secured from Washington and from Alaska, where there is a supply sufficient to last us for hundreds of years. Besides this, our ports are open to the commerce of the world. The demand for coal will assist our trade by providing a return cargo for our ships, and the greater our export trade, the easier it will be to secure an adequate supply of coal.

THE RAILWAY FUEL PROBLEM OF THE PACIFIC COAST

By J. C. MARTIN, JR.,[1] SAN FRANCISCO, CAL.

INASMUCH as fuel represents the second greatest item of the operating cost of a railroad, its importance cannot be underestimated. In order to have a clear understanding of the amount of steam fuel annually used by the Pacific Coast railroads, it is first necessary to know to a reasonable degree of certainty the quantity that must be provided and how its transportation can most expeditiously be arranged for to meet the demands of service.

In the states of Washington, Oregon, California, Nevada and Arizona there are now 4002 locomotives. Figuring that under normal operating conditions the modern locomotive consumes daily an average of 10 tons of coal, and that 90 per cent of the locomotives are used daily, in order not to underestimate the amount of fuel required, we find that the total fuel consumption per year is 13,146,570 tons. Considering the average B.t.u. content of the coal used as 12,500 per lb. and that 4 bbl. of fuel oil (42 gal. per bbl.) of 18,500 B.t.u. per lb. is equal to one ton of this coal, we have an equivalent of 52,586,280 bbl. of fuel oil required annually.

With this information in hand and considering that any hydroelectric development which would effect steam railroads by putting into use electrical units on certain divisions instead of steam-operated locomotive units would, in the development of our Pacific

---

[1] J. C. Martin & Co., Mem. Am.Soc.M.E.

Coast section during the next twenty years, call for further steam locomotives, to the extent that the total number of locomotive steam units will be substantially the same as today, it is then necessary to determine where the segregation of fuel oil and coal can best be made to serve the respective state mentioned from an economic point as well as a conservation of supply for the next twenty years.

Of first consequence is the matter of securing an adequate supply to meet the demands of service, for obviously without fuel operation ceases; and secondly, to lay down the most economical fuel to use in that particular state or territory in which the locomotives are operating, the kind of fuel used being governed very greatly by the transportation costs plus the fuel costs overlapping the equivalent B.t.u. value of the coal or fuel oil.

It is extremely difficult to assume what the future has in store in the way of railroad-locomotive fuel oil, as predictions in the past have been so materially upset through the development of new oil fields of consequence even in the past two years, which today have a direct bearing on the fuel-oil situation in California and the Pacific Coast, that the best we can say at this time is that, in view of reliable statistical information readily obtainable on the coal supply, there is sufficient fuel oil and coal directly within or immediately adjacent to the states of Washington, Oregon, California, Nevada and Arizona for the next twenty years, if properly segregated, conserved and restricted to the districts in which it should be economically used. This leaves fuel oil for railroad use entirely within the state of California, should the present processes now in the state of perfection, involving improved methods of cracking and refining, materially reduce the amount of fuel oil over that at present being produced to such an extent that no shipment out of California to other adjacent states could be made without detracting from California railroad requirements. It is quite true that it is within the possibility of cracking processes to materially increase the output of the lighter fractions in the crude so as to leave only a relatively small fraction of fuel oil, yet there is a question just how far practically this will go, as no means or system has yet been devised to properly handle in the locomotive firebox, for combustion purposes, or in fact the combustion chamber of any furnace, the so-called pitch or coke which is the final issue of the ultimate cracking process. This pitch has given considerable concern in firing owing to its adhesive nature.

Again, we find that the production of California crude oil has materially increased in 1921 over 1920, the total production in 1921 being 114,849,924 bbl. which exceeds the 1920 production by 9,128,738 bbl., and that the total crude oil stocks on December 31, 1921, were 35,021,912 bbl. as against 22,240,271 on December 31, 1920. The storage increase during the year being 12,781,641 bbl. and the daily gain 35,018 bbl.

At the present point it is illuminating to call attention to the report of the Fuel Committee of 1917, appointed by Governor Stephens to investigate the consumption of fuel oil. That part of the Committee's report and findings in reference to the consumption of fuel oil keeping pace with the production is herewith set out:

> The consumption in 1916 outran production an average of 1,100,000 barrels per month and 35,650 barrels per day.
>
> During the first five months of 1917, consumption outran production 5,415,000 barrels, being 1,083,000 barrels per month and 35,860 barrels per day.
>
> Consumers of California petroleum will shortly face a condition of decreasing production and increasing demand. This condition points inevitably to the necessity of developing other sources of fuel or power.

There is no question but what this committee used extreme care and handled the situation in a masterful manner at that time, but as previously stated, it will always be extremely difficult to determine, with any degree of certainty, just what the future sets forth in the way of fuel-oil supply and this is no better evidenced than by the Standard Oil Company's report of 1921, which shows that the production of crude is now 35,018 barrels per day ahead of the consumption, whereas in 1917, production of crude was 35,860 barrels below consumption.

At the outset the logical thing to do is to use the kind of fuel best and most economically obtainable in sufficient supply in that particular state of our Pacific slope where it is best found. As long as fuel oil is produced in California in sufficient quantity to ship to other adjacent states for railroad use, it is the ideal locomotive fuel for the railroads of such states to buy, provided suitable contracts to give them a reasonable assurance of at least three years' time can be entered into, and even on the basis that transportation costs on a relative B.t.u. basis of oil vs. coal show coal to be equal in price to fuel oil. This latter statement requires an explanation in that the modern fuel-oil-fired steam locomotive is conservatively 10 per cent more efficient than the same locomotive coal-fired either by hand or automatic stoker. The stoker as applied on the locomotive does not show the same degree of efficiency as compared to oil firing as does the automatic stoker applied to land-fired boiler furnaces shows to oil firing. It is the ability to maintain a practically constant boiler pressure in the modern oil-fired locomotive within 5 lb. of the pressure for which the pop valves are set that brings about this increased efficiency, whereas it is impossible to do so in meeting the maximum demands of service with the hand firing of coal or by stoker firing, which latter simply accomplishes what man cannot do physically, but without any greater efficiency in fuel saving.

Again, the ability to increase the steaming radius of the oil-burning locomotive over the coal-fired engine, whether hand- or stoker-fired, is greatly in favor of the use of oil, it being possible, for example, on the Southern Pacific System in California to operate an oil-burning locomotive a distance of 537 miles in passenger service from Sparks to Ogden without taking oil, this being over two passenger divisions, whereas it would not be possible through the use of coal with the accompanying necessity of cleaning fires to operate these engines coal-fired over more than one division.

From an operating point of view, this makes available power in oil-burning locomotives not possible to obtain in coal-fired engines, and it is a generally accepted fact in operating that for every ten oil-burning engines fitted there is the equivalent of one extra engine available for service over coal-fired engines.

From the foregoing it would therefore seem that, as far as it is within our knowledge to know at this time, we have ample fuel in the Pacific states to meet the present demands, if proper judgment and regard are used in their distribution, and probably so for a period of twenty years to come.

In conclusion, we can justly expect that in view of the great economy of fuel in locomotive fireboxes and its ability to increase the steaming radius of the locomotive, as it were, making available the maximum operatable locomotive power for the hauling of tonnage, that oil fuel will have precedence in railroad use over any other land-fired uses, should, for any reason, steps in the direction of conservation be required to be taken on account of declining production.

THE MARINE FUEL PROBLEM OF THE PACIFIC COAST

By D. Dorward, Jr.,[1] San Francisco, Cal.

In the operation of the American Merchant Marine there is no one problem more vitally important than the question of fuel, it being the dominant factor attending steamship operation and the largest single item of cost entering into the operating schedule of a vessel.

The greater part of the fleet of vessels now operating from Pacific Coast ports of the United States use oil as fuel, and with the exception of Australian and Japanese bunkering ports, coal supplies for replenishing bunkering stations are brought from very distant points of origin and therefore the cost of bunker coal at foreign stations, and even at Pacific Coast ports, is very high—so much so that even at the present prices ruling for fuel oil the oil-fired vessel is the most cheaply operated from a fuel standpoint.

Fuel oil as a source of power is today receiving the closest attention by maritime interests, for the world's merchant shipping is now rapidly being converted to fuel oil. The advantages derived from liquid fuel instead of coal are so important, particularly in facilitating bunkering and increasing the steaming radius and conservation of labor on shipboard, that it will undoubtedly tend to rapidly increase the use of oil as fuel, particularly in view of the highly competitive situation developing between the merchant marine of Great Britain and the United States.

---

[1] Consulting Engineer. Mem. Am.Soc.M.E.

Statistics show that at the beginning of 1920 the world's merchant shipping approximated 55,000,000 tons, of which tonnage approximately 9,000,000 tons was already on an oil-burning basis and of which proportion approximately 1,000,000 tons was fitted for Diesel-engine drive. This amount of shipping fully employed would occasion a demand for fuel oil annually of approximately 90,000,000 bbl. In 1918-1919, 12 per cent of the total world's tonnage was fitted to use oil, while in 1920 it had increased to 18 per cent.

The change from coal to oil has been occasioned by two conditions: The conversion of coal-burning vessels to an oil-burning basis and the construction of motor- or Diesel-engine-driven vessels. The adoption of the internal-combustion or Diesel type of propulsive equipment is just beginning to assume important proportions in the United States; but in Great Britain and on the continent of Europe this phase of the development has been and is making rapid strides.

The motor-equipped ship has unquestionably a strong advantage in point of economy over oil-fired steam-equipped vessels; but it is expected that the change from coal to oil as applying on the world's shipping will be greater through the intermediate stage of oil-fired steam vessels, which it is expected will create a requirement of at least 10,000,000 bbl. of fuel oil for each million tons of shipping using oil as fuel. Practically all of the vessels in operation by the United States Shipping Board and under private American ownership are substantially on an oil-burning basis, there being 49.4 per cent of these ships exclusively oil burners, 23.3 per cent coal burners, and 27.3 per cent convertible to burn either coal or oil.

In 1920 the fuel-oil requirements of the United States Shipping Board were in excess of 30,000,000 bbl., and while this demand was somewhat curtailed during the industrial depression of 1920–1921, it is expected, however, that the resumption of international trade will not only revive but intensify the fuel requirements of the merchant-marine fleet.

The navies of the world are largely on an oil-burning basis, for the advantages of oil over coal for naval operations are of the utmost importance and undeniably make for greater efficiency. While the naval demand for fuel oil is small in comparison with that required by the merchant marine shipping, there are, however, about five million barrels required annually for the American Navy.

It is now more than evident that oil for merchant-marine transportation has assumed a standing of the utmost importance and it has been conceded by well-known authorities that the strength of this demand is such that if necessary it can and will divert from industrial purposes the quantity required for shipping interests. At any rate, the significance of oil in maritime matters explains to a considerable extent the present world-wide interest that has been shown in oil. Particularly Great Britain has, by her policy in acquiring foreign reservations of petroleum, indicated beyond question the great advantage of fuel oil for naval operations and ocean transportation, and which factors have in addition been the source of much activity in the United States.

In the use of fuel oil on board vessels there are many economical features involved which would make the continuance of the use of oil as a fuel for maritime purposes of the greatest importance, and which are briefly summarized as follows:

More economical operation
Reduced crew
Greater cargo capacity of the vessel on account of its ability to carry oil in compartments not otherwise available for cargo, such as double bottoms, peak tanks, etc.
Ability of vessel's propulsive equipment to render more continuous service, steady steaming and uniform speed, thereby tending for more efficient operation
Lessened wear and tear on vessel's equipment, machinery, boilers, and reduced cost of upkeep
Less frequent painting
Preserving effect of oil on vessel's double bottom, it being rarely necessary to undertake the most expensive item of renewing tank tops in oil-burning vessels.

On large passenger vessels fitted for oil fuel it has been noted that an enormous saving in operating costs has been effected on account of lessened wear and tear on such items as carpets, draperies and cabin equipment.

The great problem confronting steamship operators today is the question as to whether the world's supply of petroleum is sufficient to sustain automotive transportation on land, industrial power plants, lubrication requirements of industry, and whether the supply will support the great change in the conversion of ocean shipping to an oil-burning basis.

Were the 55,000,000 tons of world's ocean shipping converted to an oil-burning basis, it would require an annual consumption of over 500,000,000 bbl. of oil, which represents nearly the total quantity of petroleum produced in the world today. While this consumption could, of course, be somewhat reduced by a more universal adoption of Diesel engines, it would, nevertheless, be of huge proportions.

Utilization of oil by ocean shipping, however, is today governed largely by the matter of price; and upon the production of the world's most extensive deposits being exhausted it is possible that some reduction may be forced in the amount of fuel oil used for maritime purposes. This possibility seems to have been lost sight of under the present competitive conditions existing and on account of the great advantages offered by the use of fuel oil at the present price level. Regardless of the future of fuel oil, the fact remains that it is now definitely involved in competitive shipping efforts and its use is fully expected to grow for a considerable period at least.

Powdered coal is still in an experimental stage and it is questionable if its use on board vessels could be attended with any degree of success. It is expected, however, that the development of automatic stokers for use on shipboard will aid materially in the continued use of coal for marine purposes.

The consumers of petroleum oil are now facing a condition of decreasing production and increasing demand, which condition points inevitably to the necessity of developing other sources of fuel for power.

Hydroelectric plants can aid materially in the conservation of fuel oil in the power they produce, but industrial plants, railroads, and similar institutions will eventually have to find other sources of power than that developed by fuel oil, in order to supply the increasing demand for marine purposes, although of the substitute fuels coal will undoubtedly occupy the chief position.

Even at this stage it is significant that coal is now being brought from Australian ports in American vessels using oil as fuel; and large steamship companies having many vessels usually confine that portion of their fleet operating in Pacific Coast waters to those vessels fitted for oil burning.

Approximately 60 per cent of the crude oil produced in California is refined, at least in part, before being utilized. The increased demand for gasoline and lubricants and the rapid strides in refinery efficiency are resulting in the refining of a constantly increasing proportion of the oil with a resultant smaller quantity available for fuel purposes. Practically 50 per cent covers oil exports to the Orient from California ports, though these exports are confined mostly to fuel oil to Hawaii, Central America and South America, gasoline and distillate to Australia, and kerosene to the Far East.

The demand for refined oil products is rapidly increasing and will be accelerated by the potential oil shortage in other fields of the United States and by the necessity of using California oils to offset this shortage. To meet this increasing demand, California oil must be used more efficiently and sparingly.

California now produces between one-quarter and one-fifth of the world's supply of petroleum oils and one-third of the United States' supply. Statistics show that to January 1, 1921, the United States had produced 5.4 billion barrels; and subtracting this quantity from the original supply of 11.3 billion barrels as estimated by the U. S. Geological Survey in 1918, would leave as a working reserve only 5.9 billion barrels, with the annual requirements running over half a billion barrels.

Important strides have been made in refinery efficiency, also in number of refineries. The refining capacity of the entire country increased 18 per cent during 1919 and 23 per cent in 1920. This increase in refinery capacity together with greater efficiency will certainly have the effect of reducing the quantity of oil available for fuel.

It is a fact, however, that petroleum cannot be expected to radically displace coal in industry and transportation, since a crude

petroleum production of about three billion barrels per year would be necessary to drive coal from its present position.

For the future, fuel oil will represent a reducing percentage of the crude petroleum produced, for the more specialized uses, such as automotive power, lubricants and chemical by-products are coming into more importance and must be considered in preference to the demand for industrial fuel. However, fuel in liquid or gaseous forms is of such importance and has so many advantages in convenience and efficiency that it may reasonably be expected to continue to supplant solid fuels, which solid fuels must take second place as regards certain industrial uses and marine propulsion.

The output of crude petroleum in the United States is conceded to have virtually reached its maximum, and as the proved fields of Mexico are showing a rapid decline, a marked falling off in imports from that source may be expected.

Cheap supplies of petroleum will soon be a thing of the past; and the answer to the domestic petroleum problem does not lie in importations from foreign sources.

Efficiency in production and utilization and supplemental sources of supply at home must share with foreign supplies the responsibility of sustaining those activities exclusively dependent upon liquid fuel, and of which none are more important than the question of fuel for marine purposes.

CONSERVATION OF THE FUEL SUPPLIES OF THE PACIFIC COAST[1]

BY F. H. SIBLEY,[2] RENO, NEVADA

THE three papers presented have raised so many interesting points for consideration that a discussion of them becomes a somewhat difficult matter of selection. Reviewing the papers, four points stand out prominently:

1 The paramount importance of an adequate supply of fuel of one sort or another (regardless of other sources of power) if industrial activity is to increase or even continue at its present rate.
2 To maintain this supply new sources will probably have to be developed in the not distant future.
3 Conservation of present available supplies must be looked after.
4 If restrictions on the use of fuel oil become necessary because of a diminishing supply, such restriction should not be placed on the use of oil for locomotive and marine service, because of its great convenience as well as efficiency for such service.

The first point mentioned, i.e., the importance of an adequate fuel supply, may well pass without further discussion.

As to the second point, namely, that of developing outside sources of fuel supply, it would be interesting to learn what forces are holding back development in Alaska; whether satisfactory trade relations, tariffs, etc., will be established between Canada and other countries so that fuel can be profitably imported to the Pacific Coast states; whether supplies from Columbia, S. A., said to be one of the greatest potential oil-producing countries in the world will be available in this group of states through the Panama Canal; whether the Philippine Islands, said to contain vast supplies of coal and oil that are only awaiting capital for their exploitation, will serve as a source of supply for the Pacific Coast states; and whether the peninsula of Southern California has ever been extensively explored for fuel deposits.

The third point, conservation, constitutes the great ready-to-hand problem of engineers not only here but in most other parts of the country. There are two main factors, it would appear, in the conservation of our fuel supplies:

(*a*) Prevention of waste and (*b*) increasing the efficiency of power equipment.

Fuel wastes again may be classified under two headings, namely, direct waste and indirect waste.

Few outside the engineering profession and by no means all engineers realize how enormous these wastes are. The Bureau of Mines is authority for the statement that 122,000,000 gal. of gasoline, representing a value of $26,000,000, are wasted annually by evaporation from storage and transportation. It has also been stated that $1,000,000 are lost by fire, due mainly to electrical discharges at storage tanks.

A recent news item stated that 5,000,000,000 cu. ft. of natural gas was wasted from four wells in Texas in a period of a few weeks. Another stated that a 100,000-bbl. well ran wild for twelve days in Mexico. Similar losses are recorded weekly from almost every production center.

These are direct and obvious losses and if we examine into the less obvious wastes of useless activity we find the situation no less disheartening. For example the Bureau of Mines, again informs us that the needless use of passenger cars consumes a million gallons of gasoline a day. Wastes from leaky carburetors, idling motors, etc., amount to half a million more.

When we turn to the question of fuel efficiency in power equipment we see that real progress has been made in the past twenty-five years in that such efficiencies have been nearly doubled, but there is still room for improvement when we consider that of the total production of fuel for power purposes only a pitiful ten or fifteen per cent is transformed into effective work.

Estimates of time that fuel supplies will last are based, rightly enough, on the assumption that losses will continue to increase with consumption or at least will continue at somewhere near the present rate. But will they? And if not, how are we going to prevent it?

The following suggestions are most of them old. Some of them may be visionary. But the visionary things of today often become the realities of tomorrow. At any rate a discussion of them may be worth while, even if they should lead only indirectly to better conditions.

1 Getting a larger proportion of oil from the sand. Lewis of the Bureau of Mines estimates that an average of only 20 per cent of the total petroleum in the ground is recovered by present methods. In Louisiana and presumably in California also are crudes of such low gravity that they can not be removed by pumps at all. Driving off this oil by air or water has not, in the main, been very successful. What about the suggestion to mine the oil sand? The problem apparently presents no difficulties not met with in other forms of mines, and if these sands contain from 50 to 80 per cent of the original oil, mining them would seem to be a better proposition commercially than distilling oil shales.

2 Making greater use of slow sailing ships to transport cargoes not subject to deterioration.

3 Development of artificial fuels, mixtures of alcohol and benzol being an example.

4 More efficient prime movers. The advantages of the Diesel motor for marine service have been pointed out in Mr. Dorward's paper. Compounding it may give even better results. Should it be applied to railway locomotives as well?

5 The substitution of large central stations for small individual plants should, and doubtless will, go forward. The gain from this change is larger even than most people suppose. Small plants where the overall efficiency is probably not more than two or three per cent are still all too common.

6 More scientific study of storage and other field conditions both in coal- and oil-producing districts should be made. Problems like proper painting and roofing of oil tanks to prevent evaporation losses and fire losses due to electrical discharges need more systematic study.

7 Finally as to indirect wastes due to careless or useless activities. Here is where our economic education comes in. Will people in time become wise enough to realize the wickedness of using a 60-hp. automobile for pleasure purposes when 25-hp. might do as well? Will those who have no special business abroad learn to amuse themselves at home? Shall we ever learn to stop taxing ourselves for hauling thousands of tons of worthless literature and other junk in the mails?

While this is taking rather high ground, these are some of the things we must learn if we are to keep up the present rate of industrial progress and provide for all *worth-while* activities, without exhausting our supplies of fuel before we have learned perhaps better and cleaner methods of producing power.

A Review of Attainment in Mechanical Engineering and Related Fields

AIR MACHINERY

Efficiency of Single-Blow Pneumatic Hammers

Single-Blow Pneumatic Forging Hammers, W. H. Snow. The author starts with a general discussion of factors affecting the efficiency of self-contained pneumatic hammers and gives diagrams to explain the relation between the movements of the pump and hammer pistons.

The single-blow hammer described in the present article is based on the idea that with the valve designed so that more use can be made of the pump as a compressor and air can be led into the hammer cylinder, above as well as below the piston, there exist the elements of a control of the up-and-down movements analogous to that obtaining in the ordinary double-acting steam or air hammer.

The simplest design of such a valve is shown in Fig. 1. If the valve be moved from the hold-up to the hold-down position a single blow will be struck. Air compressed under the pump piston passes through the one-way valve *B* into the belt *D*, and by a passage not shown to the top of the hammer cylinder. The air below the hammer piston is exhausted through passages *C* in the tube and openings *C′* in the valve. This arrangement, however, is not as efficient as it might be. The blows will not be very powerful as compared with the pump pressure, and furthermore they can be produced only comparatively slowly.

Because of this another design shown in the original article has been worked out. In this both ends of the cylinder are brought into use and the pump works as a double-acting compressor.

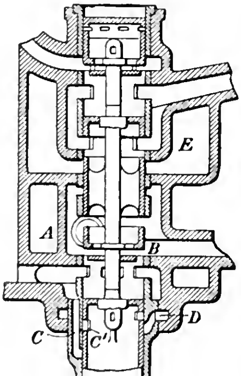

Fig. 1 Operating Valve of Single-Blow Pneumatic Forging Hammer

The governing is effected by a special rapid-acting unloading valve, which opens a by-pass *F* when the maximum pressure is reached. Finally, storage of the compressed air is arranged for in a reservoir formed in the cylinder-casting (which can, if necessary, be connected to an outside receiver to increase the storage).

The single-blow, hand-controlled, independent action in this case, where heavy blows can be struck at about one-third the rate of the automatic blow, becomes a real improvement, particularly in the larger sizes of hammers, enabling the miscellaneous processes of flattening, straightening, edging, setting, cutting off, stamping, etc., to be carried out with precision, speed, and safety. The order of events in the operation of the hammer, beginning with the valve lever in the raised position, is: (1) hold up; (2) hand blow (and hold down); (3) not working (hammer at rest, pump by-passed); (4) light automatic blows; (5) heavy automatic blows.

The heaviest blow than can be struck depends on the size of the reservoir, the pump displacement during the short time the hammer is falling being too small to affect the pressure. With a small reservoir the expansion will be considerable and the mean pressure and force of blow will diminish. The efficiency improves with increased expansion, but on the other hand the charging up of the reservoir ready for a second blow proceeds from a low pressure, and the work the pump can do in a given time is less than with a larger reservoir and smaller range of pressure. The best results are obtained with the latter, enabling the pump and motor to work up to their maximum capacity; but if the reservoir is too large, the time taken to charge up after a period of automatic working, during which the reservoir pressure may have run down, may be inconveniently long. Fig. 2 shows the results obtained with different reservoir capacities, ab and ab_1 being reservoirs of volumes 1 and 2, respectively, while cd is the hammer-piston displacement. The efficiency for ab (ignoring compressor and clearance losses) $= \frac{acdg}{acd_1g}$ and for $ab_1 = \frac{acdh}{aceh}$. Suppose $cd = ab$ and pressure = 30 lb. per sq. in. (gage). Then efficiency (1) = 90 per cent and (2) = 78 per cent. The work obtained is given by the numerator. The work done in recharging is $aec - c_2cc_1$ and $afc - c_3ec$, respectively. The ratio of work obtained in the two cases is 1:1.30, and of work done, 1:1.50. More work to the extent of 50 per cent can be done in the air with the larger reservoir. The work obtained is 30 per cent greater, the efficiency being less.

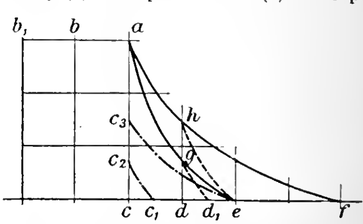

Fig. 2 Diagram Showing Hammer Results Obtained with Different Reservoir Capacities

While some hammers constructed on these lines have given satisfactory results over a considerable period, there are certain objections to the design, such as the extra first cost. Also, a single mishap, such as the failure of a valve or spring, may lead to unsatisfactory performance of the hammer through possibility of wrong assembling, and this latter might easily take place where the control valve and other parts are assembled by men accustomed to deal only with the ordinary plain equipment of a forge. An analysis of conditions therefore leads the author to take a rather gloomy view of the possibilities of single-blow pneumatic forging hammers. (*Engineering*, vol. 114, no. 2952, July 28, 1922, pp. 98 to 109, illustrated, *d*)

ENGINEERING MATERIALS (See also Machine Tools, Testing and Measurements, and Welding)

Lecfurite—High-Resistance Alloy. Brief and incomplete data on a alloy developed by an English company for use in place of such materials as nichrome.

The melting point of the material is said to be approximately 1550 deg. cent. (2822 deg. fahr.), tensile strength, 42.26 tons; elongation, 27.5 per cent; reduction of area, 68 per cent; and Brinell hardness, 187. The material can be welded, rolled, drawn, or stamped, and resists the action of most acids and alkalies. No data as to its composition are given. (*Machinery* (London), vol. 20, no. 511, July 13, 1922, p. 552, *d*)

FOUNDRY

Making High-Grade Castings Direct from the Ore, F. H. Bell. Description of a process experimentally used at the Ford Motor Works. The process has not yet been carried out to the stage where it can be called successful, but it is said that it is by no means a failure.

In this process (used at the River Rouge branch) the metal is obtained direct from a blast furnace of a construction somewhat different from that of the usual type. Different grades of ore are mixed with the view to getting the required chemical content. As ore is never uniform, every batch has to be analyzed to make sure

that it is right. The least error in charging a furnace may make a big difference in the resultant metal.

From the furnace the iron is poured into a big container, in which the metal is held while the chemist is making his calculations. This container is built on the principle of a thermos bottle, Fig. 3. It consists of one shell within another with an airtight space between, the inner one being lined with firebrick. At one end is a tap hole near the bottom, while at the other end and on the top is an opening into which the metal is poured from a 75-ton ladle.

A certain number of cupolas are always in operation melting scrap from former heats, pig iron and such special metal including steel scrap as it may be desired to mix with the furnace iron to bring it to proper analysis. The analysis of this cupola metal is fairly well known in advance and the additions are determined on the basis of the analysis in the thermos-bottle container.

The metal which is very hot when put in the container will remain hot for as long as five hours. Casting direct from the ore, therefore, does not differ essentially from the ordinary processes, except that it represents a very large outlay of money and could not be applied to a foundry of ordinary size. (*Canadian Foundryman and Metal Industry News*, vol. 13, no. 7, July, 1922, pp. 17–18, 2 figs., d)

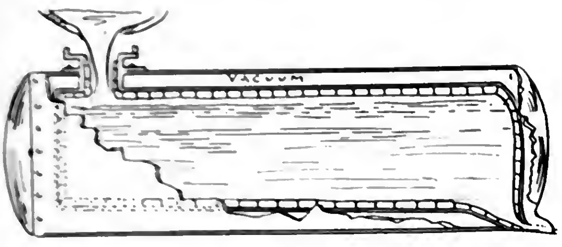

Fig. 3 Sectional View of Mixer Used by the Ford Motor Co. in Making Castings Direct from the Ore

FORGING (See Air Machinery)

FOUNDRY

Gearing and Ladle Operation. Analysis of the performance of various types of gearing as affecting ease in handling and safety of ladle operation.

The conditions of operation of gearing on ladles are rather strenuous. With most styles of geared ladles the expansion and contraction affect the alignment of the gearing. In many foundries the lubrication of ladle, gears, and trunnions receives little attention and this results in excessive wear and trouble. Unless gears, cups, and oil holes are located so that the lubricant gets to the bearings and gears in sufficient quantity, the ladle gearing will suffer, no matter how much care is exercised.

When lost motion is present in the gearing, a dangerous drop of the ladle occurs during pouring, caused by the flow of the metal. This usually results in a splash of molten metal, which may cause serious injury to the men around.

On the other hand, if the gears are too tight and bind, pouring becomes difficult and may lead to cold shuts and misrun castings.

The oldest type of gearing applied to a ladle was the worm, and it is still quite extensively used. Spur-geared ladles appeared in this country about 30 years ago in pipe foundries where a ladle operating faster than worm gearing permitted was desired. The most recent type is the helical form, which is said to be more efficient than either of the two older types. In this the housing is mounted on the trunnion and has no attachment to the bail except through a sliding support. This makes the tilting mechanism an independent unit, with the result that the alignment of the gears is not affected by the distortion of bail or bowl or by wear on the trunnion journals. In addition to this the gear is self-locking, requires little power to operate, and permits a wide range of tipping speeds.

The location of the trunnion is important, as shown by deductions from curves in the original article giving the turning moments of a 10-ton ladle at various angles. From these it appears that moving the trunnion 1 in. upward or downward changes very materially the moment required to tip or right the ladle.

The original article shows also how to calculate the force required on the handwheel for operating a given ladle. (Paper presented at the Rochester meeting (June 5–9, 1922) of the American Foundrymen's Association, abstracted through *The Foundry*, vol. 50, no. 16, Aug. 15, 1922, pp. 682–684, p)

FUELS AND FIRING

Colloidal Fuel, Lindon W. Bates. A description of the manufacture and some of the uses of colloidal fuel.

Colloidal fuel is a mixture containing pulverized coal or coke stably suspended in mineral oil or a blend of oil and liquid derivatives of coal.

To prevent settling out of the coal a stabilizing treatment is given. For this the following may be used singly or in combination. In the first place, the solid fuel may be ground to a fine state of subdivision, which is, however, a somewhat costly method. Next comes saponification, which may be accomplished by adding to the oil a soap such as a lime-rosin soap, thereby "fixating" it. About one per cent of rosin and one-half per cent of lime will serve.

Resinate of calcium gives the most persistent stability. Peptization may also be used. This is obtained by digesting bituminous coal with a moderate percentage of creosote or other coal distillate under a heat treatment of 180 deg. fahr. for over an hour.

The plant necessary for the production of colloidal fuel is described in general terms in the original article and is said to be comparatively simple. The original article presents a general discussion of the prospective field for colloidal fuel and data of some of the tests, from which it would appear that colloidal fuel is suitable for marine use under practically the same conditions and with as good results as Navy oil. Certain grades of colloidal fuel were submitted for a rating to the U. S. Fire Underwriters' laboratories and have been in general approved by them, as it was found that they present no objectionable characteristics for use as a fuel for ordinary burning purposes as compared with ordinary fuel oil.

The flash point was found to be very much higher than usual for fuel oils. The apparent ignition temperature is likewise relatively high and the material shows no tendency toward spontaneous ignition.

The application of colloidal fuel to railroad purposes is discussed in some detail. (*Steam*, vol. 30, no. 2, August, 1922, pp. 41 to 44, *dg*)

Airspray for Boiler Furnaces

Air Spraying the Fuel. Description of an appliance for supplying air to the fuel bed in a manner believed to insure complete combustion.

The Airspray, as the device is called, comprises an air-inlet pipe fitted with a special silencing device. This pipe is carried from above the boiler to the top of the furnace front and here joins a specially constructed air-heating pipe made to stand high temperatures. This air-heating pipe is passed through the furnace front and is carried almost in contact with the furnace crown to a high-temperature air chamber built of firebrick within the combustion chamber.

The bottom of this chamber, Fig. 4, is formed by a special spraying plate. An air-balancing forked sprayer is fitted to the furnace-front end of the high-temperature air pipe and is controlled by a small valve.

The amount of air entering the air-inlet pipe is regulated by the steam coming from the air-balancing forked sprayer. The air is raised to a very high degree of temperature as it passes over the furnace through the heating pipe, when it is discharged through the open shaft into the hot-air chamber, and thence through the perforated plate in a fine spray, combining with the unburned gases generated in the furnace. It is claimed that by this method the unburned gases are consumed immediately after they have passed over the furnace bridge and before they have passed through the combustion chamber.

It is of course possible to overdilute the gases. This is said to be taken care of by the air-balancing device. It is also claimed that

the device makes combustion smokeless. Of course, if carbon particles contained in the otherwise unburned gases are consumed within the combustion chamber instead of passing through the flues into the atmosphere, smokeless combustion must result. (*Practical Engineer*, vol. 66, no. 1848, July 27, 1922, pp. 52 and 53, 2 figs., *d*)

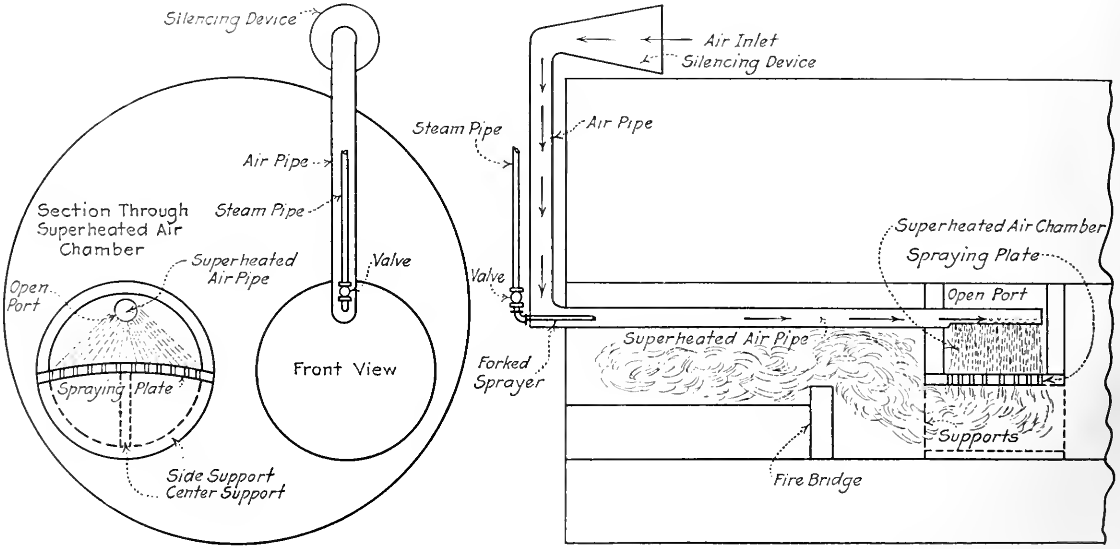

Fig. 4 Airspray Fitted to a Lancashire Boiler

GLASS MANUFACTURE

Balanced-Toggle Mechanism for Pressing Glassware

Balanced-Toggle Mechanism for Pressing Glassware. In the manufacture of pressed glassware with automatic machinery a good deal of trouble has been experienced due to the inability of the ordinary automatic press to distinguish between an over- and an under-weight charge of glass in the mold, and to apply automatically pressure of the proper degree. To meet this condition the compound balanced-toggle principle has been employed in automatic glass presses by William J. Miller, and it is said that the balanced toggle is capable of applying the correct degree of pressure to the glass, be it cut under or over weight.

As the same principle may be applicable in other lines of manufacture, some data are reproduced here.

Fig. 5 illustrates at a glance the principle of the toggle. The curved line shows how the pressure mounts and the speed decreases as the plunger advances on its working stroke, and vice versa on its idle stroke. The piston area being 78.54 sq. in. and the effective air pressure 39.5 lb., by neglecting friction the piston delivers to the toggle 3000 in-lb. for the first inch period of piston travel, and as the plunger is caused to travel 2.3 in. per inch of piston travel, it is evident that the pressure applied to the plunger is 3000 divided by 2.3, or 1315 lb. The last inch of piston travel results in only 0.03 in. travel of the plunger, therefore 3000 divided by 0.03 equals 100,000 lb. average pressure on plunger during the last inch of piston travel. This is the maximum pressure. If more glass be deposited in the mold, so the plunger can penetrate only to within 0.01 of its maximum, the total plunger pressure will be reduced $66\frac{2}{3}$ per cent or to 33,333 lb. Add enough glass so the plunger penetrates only to within 0.13 of its maximum, then the total plunger pressure will be still further reduced to 13,636 lb. Therefore as more glass is deposited in the mold, the plunger cannot penetrate so deep and consequently less pressure is applied.

By following the curve on the diagram it will be observed that, as the plunger advances into the mold, its speed of travel decreases and its power increases. Experience tells one that as the plunger advances into the glass, to propel it, due to the decreased fluidity of the glass and to the gradually decreasing space between plunger and mold wall through which the glass must be forced, an enormous pressure is required.

This peculiarity is also taken advantage of to provide a quick, reliable and simple adjustment of maximum pressure applied to the plunger. The toggle mechanism and press cylinder are suspended from the top girder of the machine by a screw secured to the top cylinder head, and this screw is provided with adjustment nuts above and below the top girder, thereby adjustably securing and locking the entire pressing mechanism at any desired height.

To reduce the pressure from its maximum of 100,000 lb. as shown in Fig. 5*e* to 33,333 lb., the operator simply lowers the pressing mechanism approximately 0.04 in. If only 7500 lb. pressure is required, the pressing mechanism is lowered so the toggles assume the position shown in Fig. 5*d*. If adjusted as in Fig. 5*c*, but 2803 lb. are applied to the plunger, and at the beginning of its stroke, Fig. 5*b*, but 1315 lb. are applied to the plunger.

It would require a monstrous cylinder with a $56\frac{1}{2}$-in. bore, supplied with an enormous amount of compressed air at 40 lb. per sq. in. pressure, to deliver the same degree of power to the plunger that is obtained with a 10-in. cylinder transmitting its power through this toggle at its maximum.

The area of a 10-in.-bore cylinder is 78 sq. in. and the area of a $56\frac{1}{2}$-in. cylinder is 2500 sq. in. Therefore, the direct-acting press will require ($2500 \div 78 =$) 32 times as much air as the toggle press at its maximum.

At the other extreme of the toggle which is at the beginning of the plunger's descent, the power applied to the plunger is over (1315 lb. $\div$ 40 =) 33 sq. in. in area, which is the area of a $6\frac{1}{2}$-in.-bore cylinder. In other words, the plunger starts down with a power equal to that of a $6\frac{1}{2}$-in.-bore direct-acting cylinder and terminates with a power equal to that of a $56\frac{1}{2}$-in.-bore direct-acting cylinder. Between these two extremes the increase of power is gradual.

No system of springs, cushions, air-control valves, etc., however ingenious and complicated, can perform the functions possessed by this correctly designed and simple compound balanced-toggle pressing mechanism. The simplicity, convenience, and freedom from breakdowns appeal to the practical glass man.

For making of high-grade pressed ware requiring a great amount of pressure correctly applied, the toggle is practically indispensable. It required years to develop this toggle to its present degree of perfection according to the statement and data presented in the original article. (*The Glass Worker*, vol. 41, no. 43, July 22, 1922, pp. 11, 29 and 30, *d*)

HYDRAULIC ENGINEERING

The California Pipe Method of Water Measurement, Blake R. VanLeer. The method described is intended for use by the man on the job who has only ordinary tools at his disposal, such as the irrigation farmer or the man operating trench pumps. It is applicable only where the discharge of the water is not submerged or under pressure

The necessary apparatus is very simple and consists only of a tee (same size as the discharge pipe), nipples, a spirit level, and a 2-ft. carpenter's rule

The California pipe method of water measurement is based upon the principle that if water is delivered to a short pipe nipple with a zero or at least a very small velocity head, then for the same size of pipe and the same quantity the depth of water in the pipe will always be the same

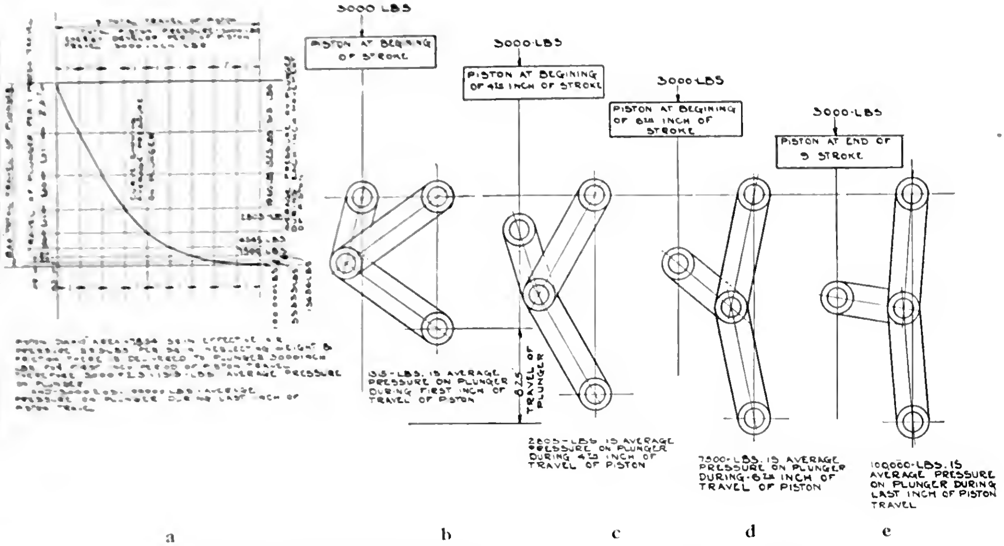

Fig. 5 Miller Compound Balanced Toggle as Applied to Pressing Glassware

In the Hydraulic Laboratory of the University of California the following general formula was derived:

$$Q = K\ (D - a)^{1.55}$$

(See Report on the Measurement of Water Discharged from a Short Horizontal Pipe, a thesis by Ejnar Smith and Clarence A. Pollard, submitted in partial satisfaction of the requirements for the degree of B.S. in Mechanical Engineering at the University of California, May, 1921.) In this formula—

Q = quantity in second-feet
K = a constant depending upon the diameter of the pipe
$= 0.0116 + 0.00787\ D$ in this general case
D = diameter of the pipe in inches
a = distance in inches from the upper inside surface of the pipe to the surface of the flowing water, measured in the plane of the discharge end of the pipe.

The formula has been checked by experimentation with pipe up to 6 in. in diameter and has been found to be quite accurate. The error was at all times less than 5 per cent.

The original article describes the apparatus and gives two sets of curves from which Q may be obtained directly from experimental data without the use of logarithms or a slide rule. One set of the curves gives $(D - a)$ plotted as abscissas on logarithmic paper against Q (quantity in second-feet) as ordinates. The other set of curves gives the relation betwen the distance a and the quantity Q in second-feet, thus avoiding the use of logarithmic paper. Finally, the original article gives tables that make the use of charts unnecessary. The original article also describes in detail the method of setting up the measuring apparatus, which is quite simple, however. (*Engineering News-Record*, vol. 89, no. 5, August 3, 1922, pp. 190–192, 3 figs., *p*)

HYDRAULIC MACHINERY (See Shipbuilding)

INTERNAL-COMBUSTION ENGINEERING

Description of Diesel-Type Engine of Unconventional Design. The engine consists of an open-ended cylinder, or rather two cylinders bolted together in the middle. Though operating together, these two cylinders are to a certain extent independent in action. Moreover, the cylinder, together with its water jacket and scavenging and exhaust branches, is free to reciprocate relatively to the two cylinder covers provided at its top and bottom. The covers themselves are made in the form of stationary pistons with gastight rings, and each cylinder cover contains a fuel valve and starting air valves.

There are certain obvious theoretical advantages in this design. The scavenging system is exceptionally good, since a thorough scavenge is obtained both top and bottom, owing to the scavenge and exhaust ports being at the opposite end of the cylinders, this, in addition, eliminating certain awkward heat stresses. The engine is well suited to accommodate expansion due to heat, which is one of the biggest problems, especially in connection with the design of high-powered engines. The cylinder is entirely free to expand both axially and radially. The combustion space takes the form of a plain cylindrical tube, entirely surrounded by cooling water and free from any valve holes. The rubbing speed of the piston is about 70 per cent of the normal, owing to the cylinder having a motion nearly synchronizing with that of the piston.

The engine upon which tests were run and which is the first of its type yet built, has two working cylinders of $11^1/_2$ in. bore and $14^1/_2$ in. stroke, and develops 240 b.hp. at 250 r.p.m. It was found to have a mechanical efficiency of 65 per cent, which is considered to be very satisfactory, since the scavenge pumps and air compressor are both overdesigned. This motor will be installed as an electric generating engine in one of the large Diesel-engined ships now being equipped by the North British Diesel Engine Works with their four-cycle Diesel motors. It is stated that the builders are considering the construction of a three-cylinder set to develop 2250 i.hp. or about 2000 shaft hp. It will have cylinders $24^1/_2$ in. bore with a piston stroke of 44 in. and will run at 100 r.p.m. (*Practical Engineer*, vol. 66, no. 1816, July 13, 1922, p. 26, *d*)

Carburetor Adjustment by Gas Analysis, A. C. Fieldner and G. W. Jones. Data of experimental work in the determination of carbon dioxide in exhaust gas from motor-vehicle engines, thus having a direct bearing upon carburetor adjustment.

The percentage of carbon dioxide in the exhaust gas bears a direct

relation to the completeness of combustion and to the air-fuel ratio.

Curves are given showing the carbon dioxide percentage relation to the air-fuel ratio and also to completeness of combustion, both by laboratory and road tests.

Characteristic curves are given of two types of carburetors, the results of which were plotted from road tests, showing how the air-fuel ratio changes with change of mixture rate through the carburetor.

Methods of procedure for sampling exhaust gases while adjusting carburetors, on the road are given, and a portable carbon dioxide indicator is described. Examples of carburetor adjustment by gas analysis are also given. (*Journal of Industrial and Engineering Chemistry*, vol. 14, no. 7, July, 1922, pp. 594–600, 10 figs., *eA*)

MACHINE DESIGN (See Foundry)

MACHINE PARTS (See Railroad Engineering)

MACHINE TOOLS

Diamond Alloy—A New Cutting Metal. Data on a non-ferrous alloy composed mainly of chromium, molybdenum, and tungsten. It is said that tools made of this alloy may be used under conditions of feed and speed that raise the temperature of the tool to the fusion point without producing softening of the cutting edge. The metal is non-magnetic.

The alloy cannot be forged and tools made from it are cast in permanent molds. Some tools are cast on a steel core or center while others are made entirely from the alloy. Diamond alloy can be welded to steel as for making laminated tool bits, which consist of a strip of the alloy welded to a strip of chrome-vanadium steel.

The following is quoted as results obtained with tools made with this alloy:

"In milling cast iron the cutter was run at a speed of 370 ft. per min. with a feed of 15 in. per min. and a $^1/_8$-in. depth of cut. In turning machine steel having a carbon content of from 0.35 to 0.40 per cent, the tool was operated at a cutting speed of 125 ft. per min. with a feed of $^5/_{16}$ in. per revolution of the work and a $^1/_8$-in. depth of cut. In turning a chrome-nickel steel shaft, the cutting speed was 125 ft. per min. with a feed of $^1/_{32}$ in. per revolution of the work and a $^7/_{32}$-in. depth of cut. (*Machinery*, vol. 28, no. 12, August, 1922, pp. 958–9, 2 figs., *d*)

MECHANICS

Contribution to the Problem of Stability of Rotating Shafts, Dr. Theodor Poeschl. Mathematical discussion of the problem. The author endeavors to establish the existence of a critical range of the second order differing from the critical velocity proper, this range denoting a periodical variation of motion appearing for certain angular velocities, and which, should it prove to be unstable—a fact which has by no means been fully established—would make itself noticeable during the passage of the shaft through the range in the course of speeding up to operating velocity.

The analysis given in the article does not solve the problems arising during the process of getting the shaft up to speed, but expresses them in the form of an equation of which the method of solution is not given. (*Schweizerische Bauzeitung*, vol. 80, no. 3, July 15, 1922, pp. 23–25, 1 fig., *m*)

METALLURGY (See Machine Tools)

POWER-PLANT ENGINEERING

Steam-Pipe Coverings at High Temperatures. Data of tests at the National Physical Laboratory and of apparatus designed by C. Jakeman. The covering under test was put on mild-steel pipes of 4 in. inside diameter with the pipe ends closed by blind plate flanges, radiation from these blank ends being taken care of by a proper correction.

The two pipes under test were respectively $13^3/_4$ ft. and 2 ft. in length. When the heats lost by the two pipes at any particular temperature are determined, the difference between the two heat values represents the loss of heat in a pipe of the differential length, namely, $11^3/_4$ ft. The pipes were heated electrically. The original article describes in detail the installation and methods of calibration.

The following data were obtained in testing an asbestos covering of very good quality:

Mean temperature of pipe	804 deg. fahr.
Mean temperature of air	68 deg. fahr.
Mean difference of temperature	736 deg. fahr.
Energy supplied to long pipe	1,216 watts
Energy supplied to short pipe	222 watts
Net energy required by the test length of pipe	994 watts

The net energy required for the bare pipe having been found in previous tests to be 13,240 watts, the efficiency of the cover is—

$$\frac{13{,}240-994}{13{,}240} = 92.5 \text{ per cent}$$

(*Engineering*, vol. 114, no. 2953, August 4, 1922, p. 155, 2 figs., *e*)

Ljungstrom Air Preheater for Boiler Furnaces

Ljungstrom Air Preheaters for Boiler Furnaces. Description of a novel type of air preheater designed by the originator of the Ljungström steam turbine and turbo-locomotive, the peculiar feature of this preheater being that it carries heat continuously in a mechanical way from the flue gases to the incoming air.

Fig. 6 shows diagrammatically the internal arrangements. Fresh air is drawn by a fan into the upper portion of the casing, which is divided into two parts by a vertical partition. The air is confined to one side of the partition, and passes downward to a similar semicircular chamber through the body of a porous cylindrical drum. The flue gases from the boiler traverse the apparatus in the reverse way, entering a lower semicircular chamber and passing upward through the drum to the upper chamber, whence they are exhausted and impelled to the stack by another fan. The porous drum is kept in a state of continual slow rotation, so that the part heated by the flue gases is constantly passing to the other side of the apparatus and giving up its heat to the cold air sweeping through it. Similarly, of course, the cooled part of the drum is continually returning to be reheated by the flue gases. It will be observed that there is no transference of heat through metal in the process. A deposit of soot or tarry matter, therefore, does not have any very serious effect upon the action of the apparatus, which, moreover, may be cleaned in a few moments by means of a steam jet. The latter blows the soot along with the air going to the furnace, so that what heat value it has is returned to the fire.

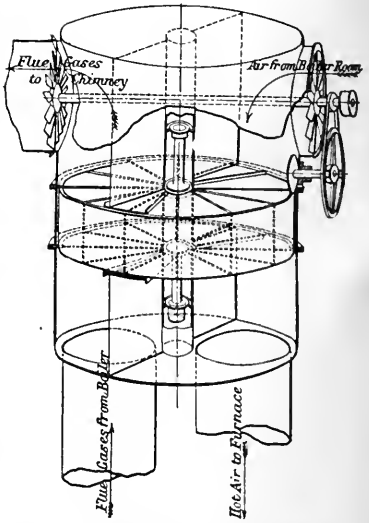

Fig. 6 Ljungström Air Preheater for Boiler Furnaces

The porous drum is built of thin sheet steel and divided into sectors by radial plates which serve as stiffening spokes. Each sector is packed with a number of thin sheet-steel plates, which are kept apart by a large number of small channel-shaped strips spot-welded to their sides.

One of the first Ljungström air preheaters was installed in conjunction with a pair of small hand-fired boilers already in service. The preheater was mounted over the flue at the rear end of the boilers and the flue gases returned to the flue outside the wall.

The hot air was led along the top of the boilers to the ashpits. A small motor of about one-half horsepower carried on a bracket from the boiler-house wall drove the fans and the rotors of the preheater.

Tests on a boiler were carried out with and without the preheater in operation. The boiler was of the return tubular type, with a heating surface of 66.3 sq. m., and fitted with an ordinary grate of 0.6 sq. m. area for hand firing. The conditions of the test were somewhat unfavorable to the preheater, as the grate area of the boiler was so small in relation to the heating surface that the waste gases normally left the boiler at an unusually low temperature. Moreover, the upper part of the boiler and the steam dome were unlagged, so that the whole efficiency was lowered by excessive radiation losses. All measurements were made in a careful and scientific manner, and the coal and the waste gases were analyzed. The results published in the official report of the Steam Boiler Association are given in Table 1.

TABLE 1 TESTS OF LJUNGSTRÖM AIR PREHEATERS

	Test 1, without Preheater		Test 2, with Preheater	
	Heat units per kg coal	Per cent	Heat units per kg. coal	Per cent
Heat transferred to steam	4509	66 9	5370	77.6
Heat lost to waste gases ..	1031	15 3	401	5.8
Heat lost by unburnt gases .	243	3 6	125	1.8
Heat lost by radiation, ash, etc	957	14 2	1024	14.8
Net calorific value of coal. ..	6740	100 0	6920	100.0

It will be noted from the first line of Table 1 that the efficiency of the boiler was raised from 66.9 per cent to 77.6 per cent by the use of the air preheater, the saving of fuel being thus about 16 per cent. No sign of overheating of the grates was observed. The rate of combustion was about normal for such grates, being 113.2 kg. of coal per square meter per hour. The air for combustion was raised from 29 deg. cent. to 135 deg. cent. by the preheater, and the flue gases were at the same time cooled from 222 deg. to 123 deg. cent.

The original article gives data of another test on a water-tube boiler.

It is claimed that the Ljungström air preheater as an alternative to an economizer is not only more efficient but is smaller, lighter, and cheaper both in first cost and maintenance, which the article attempts to prove by showing, side by side, an air preheater and an economizer drawn to the same scale and expected to achieve the same results. (*Engineering*, vol. 114, no. 2949, July 7, 1922, pp. 24 to 27, 12 figs., *dA*)

PRESSES (See Glass Manufacture)

PUMPS

Combined Centrifugal and Rotary Pump

Combined Centrifugal and Rotary Pump. Description of a pump known as the "Drum," which combines centrifugal action with that of a direct-acting piston pump.

The pump (Fig. 7) consists of a revolving piston sweeping out the cylinder at every revolution. The revolving piston dips into a revolving valve of cylindrical drum, the openings of which are so arranged that the piston passes through without slip, back pressure, or undue friction. When the revolving piston moves around from the revolving valve, a vacuum is formed into which the water flows and is forced around in the front face of the piston.

Contrary to what happens in case of the ordinary rotary pump, the present type passes the water through in one continuous flow without interruption and utilizes the power in the momentum of the moving column. As there is only one rotary working piston, the friction and strain on the gear wheels and bearings of driving a second revolving piston (as in the ordinary rotary) is avoided.

No air vessels are required and the pump works equally well in either direction and at slow speed. The quantity of water delivered is varied by changing the speed, in addition to which a by-pass fitted with a regulating valve may be used to take care of excess water delivered by the pump; throttling of suction or delivery pipes cannot be used, however. (*Practical Engineer*, vol. 66, no. 1849, August 3, 1922, p. 74, 2 figs., *d*)

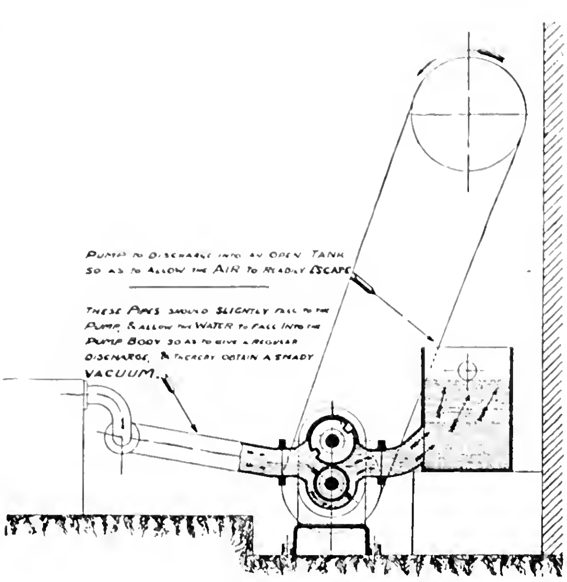

Fig. 7 Drum Pump Applied to Suction Boxes of Paper-Making Machines

RAILROAD ENGINEERING (See also Testing and Measurements)

British Gasoline Shunting Locomotive. Description of a four-wheel gasoline locomotive used at the Kelso Yards of the North British Railway.

The engine is of 40 b.hp., water-cooled. The transmission comprises heavy roller chains driving each axle in combination with a Dixon-Abbott gear box providing two speeds in both directions. The engine is fitted with four spring plunger buffers and two central spring couplings. Otherwise the locomotive carries standard equipment. (*The Railway Gazette*, vol. 37, no. 1, July 7, 1922, p. 17, 2 figs., *d*)

Roller Bearing for Railway Rolling Stock. Description of a bearing recently tested on an English railroad. The bearing includes a series of rollers of particularly hard but not brittle steel, mounted in a chain-type carrier and arranged to run between two annular members, one surrounding the axle and the other fitted into the axle box.

The rollers are of the largest diameter permitted by the dimensions of the bearing to which they are applied, and are held in position axially by links of the pattern used for transmission roller chains. One link in each set is fitted with a spring fastener designed to permit disconnection if required in the course of maintenance. (*The Railway Gazette*, vol. 37, no. 7, Aug. 18, 1922, pp. 219, 2 figs., *d*)

Large Garratt Locomotive for South African Railways. Description of a 2-6-6-2-type Garratt locomotive, said to be the largest constructed on that system. It develops 50,000 lb. tractive effort and weighs 133.75 tons when in working order.

One of the principal advantages of the Garratt system is that the proportions of the boiler are practically unlimited, it being carried by a long girder frame unencumbered with tanks, etc., and away from the wheels. Its construction is on the simplest possible lines with large water spaces, while the copper stays, etc., are readily reached for inspection and repairs, the washing-out doors etc., being usually accessible. As there are no axles under the firebox, the latter can be made of any reasonable depth and volume desired, and this feature, combined with the moderate length of the tubes, has much to do with the excellent steaming qualities and economy in fuel obtained in actual service. The ashpan also is very accessible, as not only are the ends fitted with the usual air-admission doors, but each side has a large cleaning door or doors.

The weight distribution is naturally affected by the gradual consumption of the fuel and water, but as they constitute only a small proportion of the total weight of the engine, the variation of the adhesion weight on the wheels is not a serious problem. There is always sufficient adhesion for the tractive effort, and therefore the weights of the fuel and water only represent so much extra adhesion weight. This point should be clearly recognized.

In spite of there being 2554 sq. ft. of heating surface and a grate of 51.8 sq. ft. area, the boiler is built up of only six steel and three copper plates, all of which are of plain outline. This, of course, does not include the dome. (*Railway Gazette*, vol. 37, no. 4, July 28, 1922, pp. 126–217, 2 figs., *d*)

Gasoline Switching Locomotive with Hydraulic Drive

Gasoline Switching Locomotive with Hydraulic Drive. Description of a Canadian locomotive in which the power transmission and speed control are effected by a Waterbury (Waterbury Tool Co., Waterbury, Conn.) hydraulic variable-speed gear which gives any speed from zero to the maximum in either direction without steps and gradations and without varying the speed or direction of rotation of the engine.

Neither shift gears nor electric transmission are entirely satisfactory for use on railroad equipment with internal-combustion engines, partly because of their complicated nature (electric transmission) or lack of flexibility (shift gears). The Waterbury variable-speed gear consists of an oil pump designated as the A-end and a hydraulic motor designated as the B-end.

The construction of the gear is shown in Fig. 8. The driven shaft of the A-end, which receives the power from the gasoline engine, is shown at the extreme right-hand side, while the driving shaft of the B-end is at the extreme left. A cylinder barrel (27) is keyed to the inner end of each shaft. Each barrel has nine cylinders parallel to the shaft and fitted with pistons. When the barrels revolve, their inner faces slide on the valve plates (53), each of which has two ports, the ports in A-end being connected to those in the B-end by piping. The cylinder ports in the barrel faces register with semi-annular passages or ports in the valve plates, except at the bridges at the top and bottom of the plates. The connecting rods have one end secured in the piston and the other in the socket ring (35). The socket rings are connected by universal joints with the shaft so that while they revolve with the shaft their planes of revolution may be at any angle with the shaft provided by the setting of the roller bearings on which the socket rings revolve.

In the B-end of the gear the socket ring runs in an angle box secured in the end of the case and making a fixed angle of 20 deg. with the shaft. Thus as the shaft, the barrel, and socket ring revolve in the B-end, the pistons will have a reciprocating motion with a constant stroke. In the A-end the angle box is hung on trunnions and may be adjusted to any desired angle while the gear is running by means of the control shaft. If the angle box in the A-end stands in the neutral position at right angles to the shaft, the pistons are carried around with the cylinder barrels but have no reciprocating motion. No oil is therefore taken from or delivered to the passages in the valve plates. If the tilting box is inclined by moving the control shaft, the pistons begin to reciprocate, the stroke depending on the angle between the socket and the axis of the shaft. Every cylinder during one half of the shaft's rotation is drawing in oil from one of the passages in the valve plate, which it carries over and delivers into the other passage during the next half of the shaft's rotation.

The oil from the A-end is forced into one of the passages of the valve plate of the B-end. The cylinders of the B-barrel in communication with this passage make room for the oil by sliding back from the valve plate, but they cannot do this without forcing their respective sockets in the socket rings farther from the valve plates. This can only be done by turning the socket ring as a whole in its inclined plane in the angle box. While the pistons facing the pressure passage of the B-valve plate are receding to make room for the incoming oil and so imparting rotation to the B-shaft, the pistons facing the no-pressure passage are moving toward the valve plate and delivering oil into the respective cylinders of the A-barrel. Since the receiving capacity of the B-cylinders

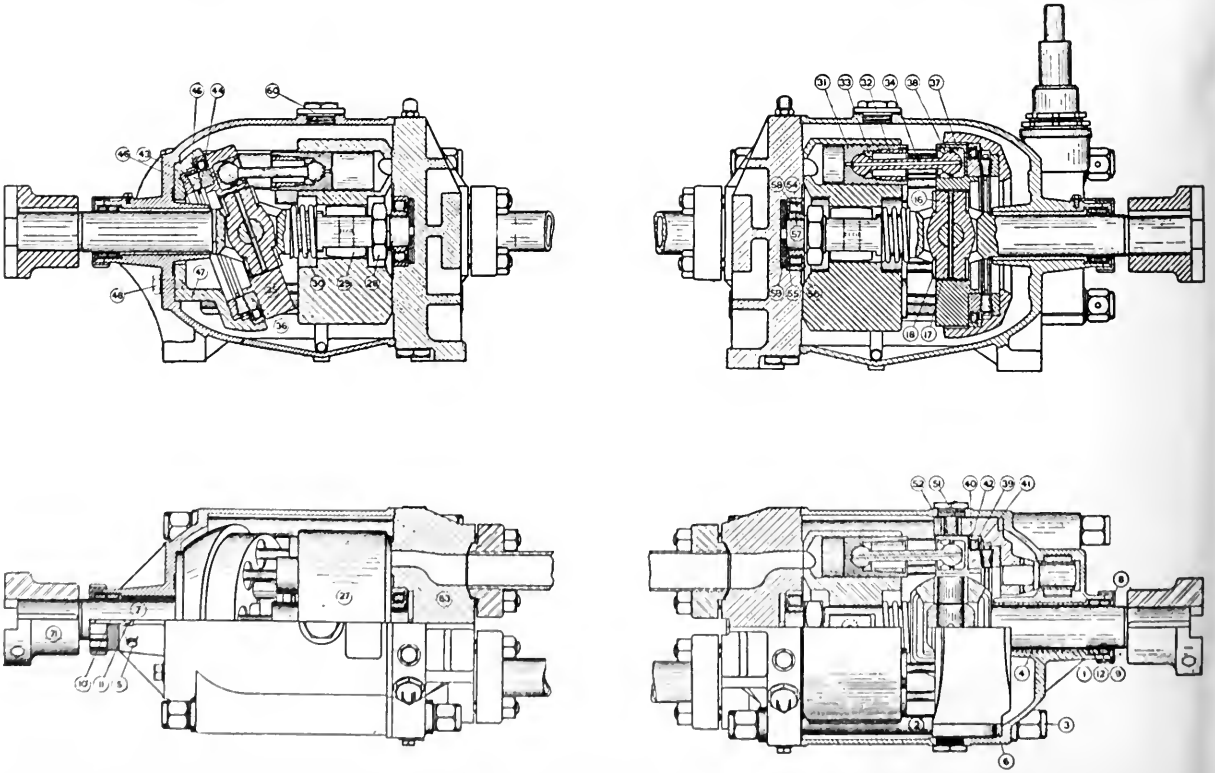

Fig. 8 Pump Unit (Right) and Motor Unit (Left) of the Waterbury Hydraulic Variable-Speed Gear on Gasoline Switching Locomotive of Universal Engineering Corporation

is constant and the delivery capacity of the A-cylinders is varied at will by turning the control shaft, the speed of the B-shaft is correspondingly varied. With the engine running at constant speed the speed of the B-end depends upon the angle which the socket ring in the A-end makes with the shaft, while the direction in which the B-end revolves is governed by the direction in which the socket ring in the A-end is removed from the neutral position.

The efficiency of this type of transmission is said to range from 68 per cent to 75 per cent at normal speed to 82 per cent at full speed, and the combined weight of pump and hydraulic motor is less than 25 lb. per horsepower transmitted.

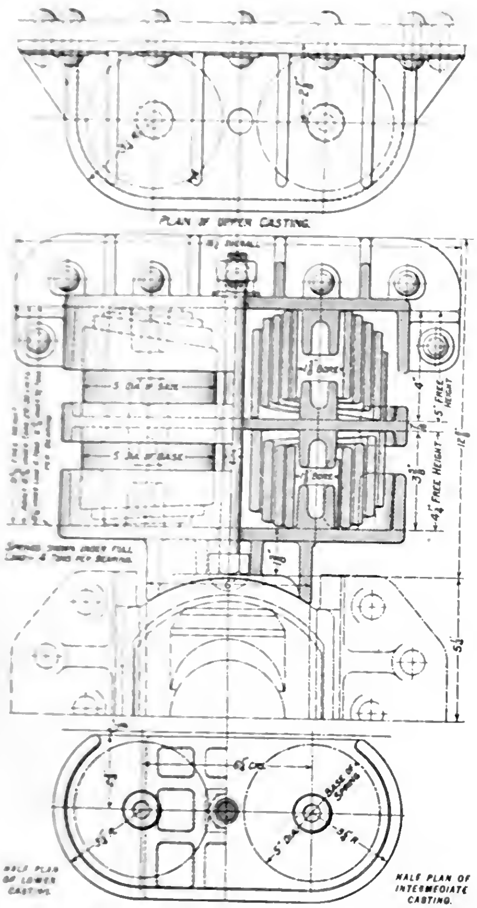

Fig. 9 Volute Spring Differential Bearing-Spring Gear as Applied to Tenders on an Indian Railroad

The control of speed and direction is effected by means of either of two handwheels placed in the driving compartment at each end, one man only being required to operate and control the locomotive, the speed of which is governed automatically by a hydraulically operated control gear which acts independently of the control shafts of the pump units as soon as the drawbar pull exceeds a predetermined amount.

In actual service the locomotive has shown great flexibility, which is of importance in switching service. The locomotive may be started under a dead load of any amount without overloading the engine, and three turns of the handwheel from the neutral position will bring the locomotive up to full speed.

In one trial the locomotive took three cars weighing 150 tons up a 4 per cent grade, stopping at the steepest point and starting again under full load without difficulty. Designs are under consideration for the application of hydraulic drive to passenger locomotives and high-capacity passenger cars. (*Railway Age*, vol. 73, no. 8, Aug. 19, 1922, pp. 323–326, 3 figs., *dA*)

Novel Differential Bearing-Spring Gear in Passenger Locomotive

Passenger Locomotive with Novel Differential Bearing-Spring Gear. Description of a 4-4-0-type meter-gage passenger locomotive recently rebuilt on an Indian railway. An interesting feature of the equipment of the engines is the bearing-spring arrangement on the tenders (known as the Herculo). As shown in Fig. 9, the springs are of the volute type, arranged in a group of four over each axle box, each group consisting of two upper and two lower springs in series. The upper springs are graduated to deflect under load at a greater ratio than the lower springs, thus insuring easy riding conditions irrespective of whether the tender is full or partly loaded. It is also said that breakage is reduced, as the total stroke is divided between the upper and lower springs; as the springs are reversely wound they have different periods and oscillation is stamped out.

An underhung differential spring gear has been employed on engine driving axles for several years on the same Indian railway and has been found quite satisfactory.

Volute springs of the same type have been used also in the engine truck control. In this arrangement two springs are reversely wound and arranged right and left hand, which prevents hunting of the truck at high speeds and restores it quickly to a normal center when leaving a curve. It is claimed in the original article that this arrangement has materially reduced the wear of tire flanges. (*Railway Gazette*, vol. 37, no. 4, July 28, 1922, pp. 124–125, 5 figs., *d*)

REFRIGERATION

Refrigerating Machine with Centrifugal Compressor and New Low-Pressure Refrigerant

Carrier Refrigerating Machine. In air conditioning it is necessary to apply mechanical refrigeration to the cooling of water near its freezing point. Neither anhydrous ammonia nor carbon dioxide have proved to be entirely satisfactory, both because of their comparatively low efficiency and exacting conditions of operation, requiring, for example, an operating engineer in the case of the ammonia system.

Furthermore, the designers of air-conditioning apparatus have been looking for some refrigerating medium that could be worked in a centrifugal type of compressor direct-connected to an electric motor or steam turbine. For this purpose ammonia, owing to the large ratio of compression, low density, and high absolute pressure is unsuitable.

For centrifugal compression a vapor of high specific density, low ratio of compression, and low absolute compression is essential, and it is stated that such a medium has been developed, although its name and formula are not disclosed.

The centrifugal compressor for use in this new type of refrigerating machine is a horizontally disposed main shaft supported by two outside main bearings. The compressor has no valve and requires no lubrication, the conditions of operation being therefore similar to those in steam-turbine practice. Furthermore, an evaporator has been developed wherein the new low-pressure refrigerant evaporates without ebullition, leaving no film tension to be overcome, which is a very important feature when working under a vacuum.

Since the entire system operates under a vacuum, special provisions have had to be made to expel all the air entering the apparatus, this being done in this case by an oil seal.

In the new machine the flash system of operation is employed. Expansion valves are not required. A steam trap can be used for feeding the liquid, hence no skilled engineer is necessary for watching the feed. Even if the cooling water is shut off, no accident can happen.

During the test the steam turbine operated at 4000 r.p.m. with 120 lb. pressure, exhausting to the atmosphere; the rated output of the turbine was 119 hp. Only preliminary tests have so far been conducted on the new machine, and no performance data are therefore available at this time. The machine is rated at 100 tons refrigerating effect for air-conditioning work. It is not intended at present for cooling liquids below 32 deg. fahr. (*Ice and Refrigeration*, vol. 63, no. 1, July, 1922, pp. 43–45, 2 figs., *dA*)

SHIPBUILDING

Vane-Wheel Propulsion

Vane-Wheel Propulsion. Description of a new type of propulsion being tested out by Wm. Denny & Bros. at Dumbarton on a vessel recently built for the Irrawaddy Flotilla Co.

Vane-wheel propulsion is intended for use on shallow-draft vessels. Vane wheels are partly immersed wheels having their axes above water and substantially in the line of advance. They are fitted with propelling vanes over the immersible circumferential portion, the vanes having a pitch so that when the wheels are rotated they exert a forward thrust on the vessel.

In order to avoid steering effect, it is necessary to have two vane wheels of identical dimensions and symmetrically placed in relation to the hull of the ship. The pitch of the vanes of one wheel is right-handed and of the other left-handed. They are rotated in opposite directions, preferably outward at the top, so that the transverse thrust of each vane is balanced by that of the other, when they are driven at the same revolutions per minute, also the steering effect of each forward thrust moment is equal and opposite.

From recent experiments, both on models and full-sized ships, it would appear that vane wheels can be profitably applied not only to such shallow-draft vessels where screw propellers are unsuitable but even to deeper-draft vessels under certain conditions, the limiting consideration being the present uncertainty in regard to the ability of vane wheels to handle rough seas.

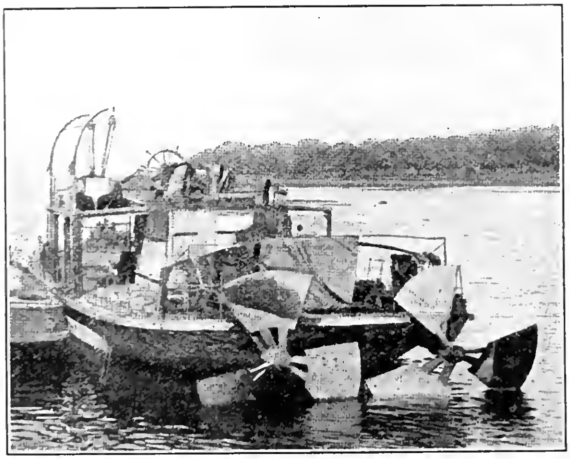

Fig. 10 Denny Bros. Experimental Vessel Fitted with Vane Wheels

The following are claimed as advantages of the vane wheel: High propulsive efficiency; on tests it has been found that vane wheels gave the same speed as twin screws (on the same vessel) with 41 per cent less shaft horsepower, in addition to which the use of vane wheels permits modifying to advantage the vessel lines and form; and great maneuvering powers, a vane wheel being capable of turning very rapidly about its own axis without advancing.

As a further advantage of vane wheels is cited the effective variation of water acted upon with variation of draft, and, therefore, variation of the thrust required. To a certain extent the same applies to side and stern paddle wheels, yet their propulsive efficiencies become considerably reduced with both overimmersion and underimmersion. In the case of vane wheels every portion of the immersed vanes is applied effectively at all drafts. The vane wheels permit of considerable variation of immersion, so that at the deeper drafts they have the advantage of acting efficiently on a greater sectional area of water, which keeps the revolutions per minute and slip for the same speed less variable in terms of draft variation than is the case with the other available methods of propulsion. In addition to this, it is claimed that vane wheels are stronger and lighter than either side paddle wheels or stern paddle wheels. (*Shipbuilding and Shipping Record*, vol. 20, no. 1, July 6, 1922, pp. 8, 9 and 19, *dA*)

Foettinger Transmission on a Liner

Foettinger Transformers on a Liner. Reference to the Foettinger transformer was made in *The Journal of The American Society of Mechanical Engineers* for February, 1914, on page 043.

The manner in which the transformer performs its maneuvering function may be briefly summed up as follows: The transformer consists essentially of an ahead and an astern "circuit," each of which is furnished with a primary wheel, guide blades and a secondary wheel, and, according to the direction of the ship, one or the other of these circuits is filled with water by the transformer pump, the water inlet and outlet being controlled by piston valves operated by a steam reversing engine. A tank is built into the framing of the ship beneath the transformer and serves to receive the water transferred during the operation of reversing, and also to accommodate any leakage water from the transformer glands. The transformer pumps, which are of the vertical type, are also placed over the tank and draw their supplies from it. In passing, it may be remarked that the turbine and transformer are separate, with an interposed thrust bearing, and are situated in different engine rooms separated by a watertight bulkhead. The reason of this arrangement is that the ship was designed shortly after the *Titanic* disaster, and special regulations were enforced regarding the watertight division of the hull. In nearly all other Foettinger installations the transformer has been built close up to the turbine, so that the prime mover and transformer together form a common unit, thus securing a close and compact grouping of the machinery. In this installation the turbine and transformer are tied together in a longitudinal direction, and are fixed to the framing of the ship in such a way that part of the thrust received by the transformer from the propeller and transmitted by it to the turbine is taken by the hull. Thrust bearings are fitted. The first transformer for this ship was completed and tested as early as 1913 at the Hamburg works of the Vulcan Company, and while the design in the main is unchanged, certain modifications have been made in the method of fastening the transformer rotors to the shafts, and in the design of the stuffing boxes, outlet channels, and cooling arrangements. At the points where the rotors project through the casing and through each other, and where the primary and secondary wheels project through each other, the peripheral surfaces are provided with brass rubbing rings, while the packing ring for the ahead primary wheel is lined with white metal.

In the present improved design of the maneuvering gear the operating of the necessary valves, both on the turbine and transformer, is carried out by means of a reversing engine, which also controls the transformer pumps which supply the water to the transformer circuits.

The steam circuit of each turbine contains an emergency stop valve which in certain circumstances is operated by the emergency gear and a shut-down piston valve which is moved by the reversing engine, while the main steam-supply valve and the overload nozzle valves may be operated by hand. Maneuvering is effected by (1) the main steam-supply valve, which regulates the supply [of steam to the turbine; and (2) by the reversing engine, which controls the piston valves on the transformer, admitting water to the ahead or astern circuits as required. The reversing valves are positively connected to the shut-down piston valve, so that the supply of steam is completely cut off from the turbine before the reversing of the transformer begins. This is necessary, because when emptying the ahead circuit of the transformer, which is no longer required for the astern course, the primary rotor is only partly loaded, and if the steam were not shut off the turbine would race. The laps of the shut-down valve and those of the reversing valves of the transformer are so arranged that when the propeller shaft is being reversed in direction the following operations take place: The steam is at first shut off, the ahead circuit of the transformer is then emptied, and the astern circuit filled by the transformer pump. Then, when steam is again admitted to the turbine, the propeller shaft rotates in the opposite direction. The reversing engine is so designed that the first part of its stroke is passed through quickly and the second part more slowly, giving sufficient time between the closing of the steam valve and its reopening for the filling up of that circuit of the transformer which is coming into action. A hand pump is also provided for hand reversing.

The transformer pump, as will be seen from the section repro-

duced, consists of a vertical-type steam turbine carrying three Curtis-type wheels, the steam inlet being governed by a nozzle valve giving steam to the required nozzles. As previously mentioned, the two transformer pumps and the reserve pump are placed over the transformer tank, and the pumps draw from this tank and deliver to the transformer circuits. In addition to the transformer pump proper, there is on each pump an overflow pump which deals with the water flowing from the tank overflow and delivers any surplus water either at the feed tanks or overboard. The steam for the transformer pumps passes through the steam-supply valve, the strainer, and the emergency and regulating valves, and the supply valve is always completely open when the pump is working.

There is also an emergency stop gear used when the pressure of the transformer pump fails and the turbine is released from its load, and when the turbine exceeds its permitted maximum speed and causes the emergency governor to operate. This gear is fully described and illustrated in the original article. (*The Engineer*, vol. 134, no. 3471, July 7, 1922, pp. 4–5, 3 figs., beginning of a serial article, *d*)

Experiments on Contrary-Turning Coaxial Screw Propellers, Gen. G. Rota. Ship propulsion by means of double coaxial contrary-turning screw propellers has long been a matter of research. In this paper are given the results of tests made at the Spezia tank. The original article gives curves showing the thrust, turning force, and efficiency obtained with various arrangements of coaxial propellers.

The experiments indicate that the arrangement described may give an improvement in total propulsive efficiency of the order of 20 per cent or more, in addition to which there will be a gain by reason of the reduced resistance of the hull itself as a consequence of the suppression of brackets, bossings, etc.

The double contrary-turning coaxial screw propellers might also be suitable for submarines with the object of obtaining the simultaneous action of both motors, electric and Diesel, for increasing the speed on the surface. It is said that this might increase the speed from, say, 12 knots to 15 knots. (*Shipbuilding and Shipping Record*, vol. 20, no. 2, July 13, 1922, pp. 47 to 49, 7 figs., *e*)

SPECIAL PROCESSES

Truck-Wheel Manufacture from I-Beams

New Process of Manufacturing Truck Wheels. Description of the process and equipment developed by the Bethlehem Steel Co. for production of wheels from rolled steel I-beams.

The wheel is of the spoked type and is punched and formed from an I-beam in such a manner that the spokes and felloe are integral, the spokes being formed from the web of the beam and the felloe from the flange. The ends of the felloe are brought into contact and electrically welded, while the spoke ends are so shaped as to "keystone" together on each side of a hub spacer.

The I-beam used in the production of this wheel has wider flanges than usual, namely, for a 3½-ton truck the flange is 10 in. wide.

The process is essentially as follows: First, holes are punched in the I-beam starting the outline of the spokes, this being done on a single-acting straight-side punch equipped with an indexing device for insuring proper spacing of the holes. The beam passes next through a coining press and die by which the sharp edges are rounded.

In the second blanking operation the outlining of the spokes is finished and the beam is cut in half longitudinally, producing two similar wheel structures, each of which ends as a complete wheel. Each of the wheel structures is then run through a press where the spokes are staggered, and, by this, spread apart at their hub ends, so that when the beam is formed to circular shape the openings left between the spokes accommodate the hub spacer. The same die which staggers the spokes also grooves them.

The forming of the wheel member to circular shape is the next stage. This is done in two operations. In the first, the ends of the beam are rounded to the shape of a quarter-circle. Before the second forming operation is started the hub spacer must be inserted between the inner and outer rows of spokes. With the hub spacer in position the wheel is bent by the second forming operation to circular shape. The press in which this operation is performed is rather unusual in size, being 118 in. between housings and having a die space of 72 in. and a stroke of 36 in. (*Automotive Industries*, vol. 47, no. 6, Aug. 10, 1922, pp. 270–273, 23 figs., *d*)

Fiber and Paper Manufacture from Reeds

Reed-Products Industry. Reeds or hydrophytes are plants of the hard kind of hydroflora, such as plain reeds, reed mace and the various kinds of rushes. They belong to the true *graminaceae* and have a stalk consisting of tubes and knots exactly similar to those of straw.

The analysis of hydrophytes shows a very high percentage of reed fiber (37 per cent), reed endosperm (9 per cent) and extractive matter containing sugar and starch (37 per cent). In addition, the root of the reed contains, roughly, 30 per cent of fiber and close to 40 per cent of extractive matter, about a quarter of which is reed sugar.

Reeds (which are here used as the generic name for all hydrophytes) contain a wealth of utilizable matter. The upper parts properly handled constitute an excellent food for cattle and were extensively used by the military authorities during the war under the name of "fragmit." The fibers of the upper reed resemble the fiber of straw and show remarkable strength.

The root fiber is particularly easy to obtain unbroken. It must be freed from the starch of the inner root and the incrustations of the outer layer of the root. But this can be done without applying expensive chemicals by the employment of a certain bacterium known as *bacillus fibrogenes Branco*. The decomposing effect of retting of the fibers by this bacterium is exceedingly vigorous, and all parts of the plant with the exception of the fibers are completely destroyed. Furthermore, the cultivation of the bacteria is very simple, a certain kind of reeds forming a good medium for this purpose. The retting is not a true decay; it begins about five to six days after the introduction of the bacteria and proceeds as a liquefaction of all the incrustations. After the roots have been treated in this way the fibers can be extracted clean and pure by simply washing the substance and without using any kind of chemical. The fiber obtained by this process of decomposition is very tough and suitable for textile purposes. The fiber of the outer layer of the root can be compared to finely separated fiber or flax, while the fiber of the core of the root represents a typical fiber that can be worked like hemp.

Practical experiments carried out on a working scale by a paper mill in central Germany have also shown that from reeds can be obtained cellulose well adapted to the manufacture of paper and cardboard. In this process the raw material is cut up into bits of 1 cm. (0.4 in.) length in an ordinary high-speed chaff-cutting machine. This chaff is fed to a beater in which leaves and parts of the plant adhering to each other are separated and the dust is extracted by an exhausting apparatus. The material is next soaked by sprinkling in large brickwork reservoirs and then boiled by means of steam. It is then ready to be worked into hard cardboard after a short treatment in a cylinder engine and without preliminary grinding, all intermediate treatment in edge mills and the like being completely eliminated. Hard cardboard does not need high-pressure treatment and has great elasticity. Unbleached cellulose from reeds is used for making all kinds of wrapping and packing papers, besides cardboards and pasteboards of various qualities, while bleached hydrophyte cellulose serves for making paper for newspapers and other printed matter, bleached cellulose also being mixed with other kinds of semi-finished cellulose such as wood cellulose, lignine and waste paper.

It is pointed out in the original article that the reed-product industry is of great importance from the point of view of world economy, partly as a source of supply of fodder, but chiefly as a means of reducing the enormous consumption of timber for paper manufacture; particularly as, according to the claim of the original article, there is actually no wood suitable for making paper in the whole of the huge stretch from 45 deg. latitude North down to the most southerly end of the continents, while reeds of a suitable character grow luxuriously in that very wood-poor area. (*Engineering Progress*, vol. 3, no. 8, Aug., 1922, pp. 181–184, 5 figs., *gA*)

STEAM ENGINEERING

Danish One-Cylinder Pass-Out Engine

Atlas One-Cylinder Pass-Out Engine. Description of an engine developed by the Atlas Company of Copenhagen, Denmark, for working economically in plants where a large heating demand exists in comparison with the power requirements.

In many industries, such as, for example, breweries, dyeing plants, etc., the proportion of power required is small compared with the steam needed for heating, and this latter is often demanded at two different pressures. In large plants of this character the pass-out steam turbine proved to be quite successful. The Atlas engine with its big valve gear is intended to solve the same problem for smaller plants.

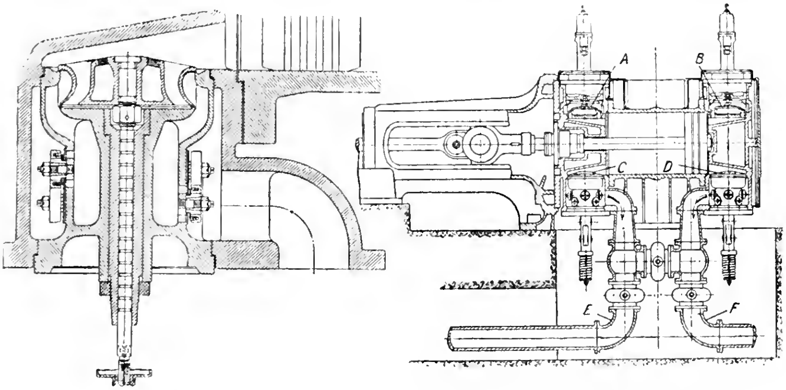

Fig. 11 Section Through Engine Cylinder of an Atlas Pass-Out Engine

The object of designing a pass-out engine is to attain maximum economy of operation by so balancing the load on the two sides of the piston that, on the one side, only the exact quantity of steam required for heating is admitted to the cylinder and exhausted to the condenser or a second heating system.

Fig. 11 reproduces a section through the engine cylinder and a detailed drawing of the arrangement of the automatic exit valves. The valves are accommodated in separate end covers, while the cylinder has a plain casting. Steam is admitted through inlet valves *A* and *B*, and is discharged through the exhaust valves *C* and *D* to the heating mains *E* and *F*. If the engine is fitted for condensing, a simple jet condenser is usually employed, with the air pump driven from the main crankshaft. Control and isolating valves are provided, and the exhaust-steam connection to the condenser may be taken from pipe *E*. The general disposition of the valve gear is indicated in Fig. 12. Double-seated drop valves are employed, and they are operated in the usual manner by eccentrics on the horizontal lay shaft. The cut-off is regulated by the speed governor, which controls the opening of the inlet valve, alternating the position of a curved lever which moves between rollers, and is attached to the eccentric rod. In addition to controlling the speed of the engine, it is also desired to balance the exhaust steam and power loads, and this is done by turning to account the variation of steam pressure in the heating mains, which variation is used independently to control and to alter the cut-off in that half of the cylinder which is dealing with the heating system. Thus, when a sudden demand for exhaust steam reduces the pressure in the heating main, the cut-off in one half of the cylinder is automatically lengthened, thereby admitting more steam, but at the same time the cut-off is reduced in the other half of the cylinder, and the balance is thereby maintained. Adjustment may be effected either by hand or by means of a special governor, which is directly controlled by the variation in pressure in the heating system.

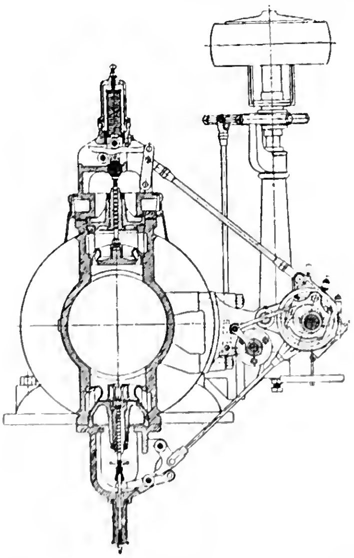

Fig. 12 Valve Gear of the Atlas Pass-Out Engine

The governing gear with hand adjustment for a single-cylinder engine is described in detail and illustrated in the original article. This part has to be omitted here because of lack of space.

The maximum back pressure against which a pass-out engine is capable of working is fixed by the initial steam pressure, and engines are generally built for back pressures varying from 5 to 50 lb. per sq. in. For a back pressure of 50 lb. per sq. in., an initial pressure of 160 to 170 lb. per sq. in. is required. The steam consumption varies according to the size of the engine and the conditions under which it has to work. The original article gives data of the test of a 280-i.hp. single-cylinder engine (19.75 in. bore, 27.5 in. stroke, running at 150 r.p.m.), the mechanical efficiencies being 92 per cent at full load, 89 per cent at three-quarter load, and 84 per cent at half load. (*Power House*, vol. 15, no. 13, July 5, 1922, pp. 26–28, 8 figs., *d*)

TESTING AND MEASUREMENTS

The Ball Hardness Tests, Doctor Moore. The author points out that the stresses developed in a specimen when a ball is forced into its surface are neither simple nor uniform. The ball hardness test is not capable of determining elementary and fundamental properties of a material and the indentation hardness as determined by the ball hardness test cannot claim to be regarded as a fundamental property. The test is purely empirical and valuable because of its practical utility. A numerical measure of hardness given by any indentation test should always be qualified by an indication of the type of test, which is the reason why we speak of Brinell hardness number. The value and meaning of the number depend upon the relations established by purely empirical methods between the hardness number and either behavior in service or other more fundamental properties.

Brinell first expressed the results obtained by the test as mean pressure per unit area; that is, as a stress. He found that the mean load per unit area increased considerably as the load was increased with the same size of ball, which was due to the fact that as the ball is forced into the material the deformation does not remain geometrically similar and the depth of the impression increases more rapidly than the diameter.

The more intense deformation produces greater strain hardening and a deep impression will carry a greater load per unit area than a shallow impression. To compensate for this effect Brinell then adopted as the hardness number the load divided by the spherical area of the impression. Though there is no rational basis for this method of impression, the Brinell hardness number

is firmly established as the accepted method. Although expressed in stress units, it is not a stress or a mean stress but a purely empirical figure derived by an arbitrary method.

The ball hardness test is applicable only to materials capable of deforming permanently under stress, that is, to materials possessing some slight degree of ductility, using this term in a wide sense. There are few metallic materials which are so brittle that a ball hardness test cannot be made on them. The range of hardness throughout which the test may be applied is very wide. There is no low limit, tests may usefully be made on lead with a Brinell hardness number over 700, the limit being somewhere in the neighborhood of 750. This may be due to the fact that as the steel ball has about this hardness, it cannot indent harder materials. Another possible explanation is that no permanent deformation can be produced in harder materials without fracture.

As regards the volume of the material to which the stress is applied, the range is very wide. At Woolwich the diameter of ball in regular use for the test ranges from 0.8 mm. to 10 mm. and a ball of 25 mm. diameter has been used. The volume of material stressed in a test varies with the cube of the ball diameter and the range mentioned is about 1 to 30,000 in volume tested.

Among other things, it has been found that, under certain conditions, a thin layer on the surface (resulting from machining, in particular planing with a shaping tool) may be harder than the rest of the specimen. This extra hardness extends, however, only to a depth of a small fraction of a millimeter. Soft metals (copper, aluminum, soft brass) are the most liable to harden on the surface when they are machined. Grinding, if properly carried out, rarely, if ever, produces this surface-hardening effect. Polishing causes a flow which is too shallow to affect appreciably the ball hardness test.

As regards the influence of the size of ball or load on the ball on the Brinell number, the author cites Meyer's second law, which he expresses in one formula and then proceeds to the discussion of the physical meaning of these laws. The Brinell hardness machine is described and illustrated. (Paper read before the London Local Section of the Institute of Metals, abstracted through *The Metal Industry*, vol. 20, no. 22, June 2, 1922, pp. 510–513, 1 fig., *dt*)

Tearing Tests of Metals

Tearing Tests on Metals, Henry L. Heathcote and T. G. Whinfrey. In impact tests, test pieces which may have given good results under the tensile test sometimes break like a carrot. It is not at all easy to break a carrot until the periphery has given way, when it tears across quite easily. The present authors have investigated this tearing and tests have shown that the tearing strength of a metal is very much inferior to the tensile strength, and of the order of about one-fifth of the latter.

Test pieces for tearing tests have to be cut from thin sheets. The form recommended is made by taking a piece of sheet about 2 in. by 4 in. in area and slitting it carefully with tinners' snips, as shown in Fig. 13, *a*. The tongue of the metal 1 in. by 3 in. is turned square out in front with the two wings exactly opposite in direction as shown at *b* on the right-hand side of the figure. This bent test piece is then mounted in a tension machine capable of registering accurately loads of a few pounds. A machine for testing paper or fabric is usually suitable. Pull is then gradually applied until the metal tears, as may be observed under a strong glass.

The pull observed is that required to tear the metal in two places and bend and unbend a total width equal to that of the specimen. In order to eliminate the work done in bending, it is necessary only to execute a similar test on a narrower or wider test piece cut from the same material.

If P is the pull required to tear, bend, and unbend a piece x in. wide, and p the pull required to tear, bend, and unbend a piece y in. wide, then $P - p$ is the pull required to bend a portion of the piece $2x - 2y$ in. wide. Therefore—

$$\text{Pull required to bend piece } 2x \text{ in. wide} = \frac{P-p}{(2x-2y)} \times 2x = \frac{(P-p)x}{x-y}$$

Pull required to tear specimen in two places =

$$P - \frac{(P-p)x}{x-y} = \frac{px - Py}{x-y}$$

$$\text{Tearing force per linear inch} \quad \frac{px - Py}{2t(x-y)}$$

where t is the thickness of the sheet.

It is apparent that the force required for bending will quite overshadow the force required for tearing in a thick piece.

It is believed that tearing tests will bring out valuable information regarding the stability of the metals tested for construction purposes, and also be of interest in connection with the investigation of the microstructure of metals and alloys.

From the appearance of the fractures which occur during the life of metals in use, it is obvious that they are for the most part tear fractures, or, as they are more commonly called, "fatigue fractures." Indeed, "fatigue fractures" doubtless start from some internal notch where the stress concentration is above the ultimate strength of the material. Probably all hardened steels break by tearing, as also do high-tensile alloy steels such as nickel-chromium steel.

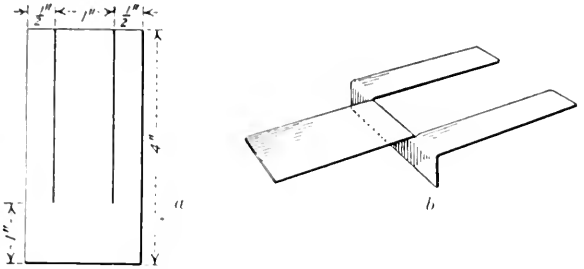

Fig. 13 Test Piece for Tearing Testing (1, Before Bending; 2, After Bending)

On the other hand, it would not do to assume that resistance to tearing should always be as high as it is possible to make it. When material is machined, the ease with which it is removed by the tool depends upon the ease with which it tears apart forward of the tool point; and a high machining speed will be obtained only when the Brinell hardness and resistance to tearing are relatively low. (*Chemical and Metallurgical Engineering*, vol. 27, no. 7, Aug. 16, 1922, pp. 310-311, *eA*)

Determining the Impact Loads on Track Bolts. Data of tests recently carried out on the Philadelphia & Reading Railway to determine the stresses in track bolts induced by the impact of trains and locomotives and the pull of a trackman on a wrench. A separate test was also made to learn the breaking strength of a track bolt and carried out under the same conditions. The load caused by the impact was measured by an adaptation of the Brinell system of testing hardness, the impact or pull of the wrench forming depressions in hardened steel washers, from which the stresses were determined.

The principle of the method consisted of the forming of impressions on hardened steel washers, through the medium of standard Brinell balls, by the loads which it was desired to determine. The original article gives the method employed for calculating the actual loads.

The average minimum and maximum loads were 25,980 lb. and 29,298 lb., giving stresses on the 1-in. bolts used of 47,236 lb. per sq. in. and 53,270 lb. per sq. in., respectively. (*Railway Age*, vol. 73, no. 7, Aug. 12, 1922, pp. 277–278, 4 figs., *e*)

CLASSIFICATION OF ARTICLES

Articles appearing in the Survey are classified as *c* comparative; *d* descriptive; *e* experimental; *g* general; *h* historical; *m* mathematical; *p* practical; *s* statistical; *t* theoretical. Articles of especial merit are rated *A* by the reviewer. Opinions expressed are those of the reviewer, not of the Society.

ENGINEERING RESEARCH

A Department Conducted by the Research Committee of the A.S.M.E.

Research Résumé of the Month

A—Research Results

The purpose of this section of Engineering Research is to give the origin of research information which has been completed, to give a résumé of research results with formulas or curves where such may be readily given, and to report results of non-extensive researches which in the opinion of the investigators do not warrant a paper.

Cement and Other Building Materials A4-22. STORAGE AND TRANSPORTATION OF PORTLAND CEMENT. The cause of the deterioration of portland cement during storage and transportation and the means of preventing it, form the subject of an investigation recently conducted by the U. S. Bureau of Mines. This report was prepared by W. M. Myers, assistant mineral technologist, and is known as Serial No. 2377.

The material for this report was gathered from all available printed sources of information on this subject and from the leaders in the cement industry. It accordingly includes a full bibliography. Address H. Foster Bain, Director, U. S. Bureau of Mines, Washington, D. C.

Foundry Equipment, Materials and Methods A2-22. INCLUSIONS IN ALUMINUM-ALLOY SAND CASTINGS. In aluminum-alloy foundry parlance, metallic and non-metallic inclusions are termed "hard spots," and in aluminum-alloy sand castings and in die castings they are very troublesome. The inclusions differ so widely that the term "hard spots" is only roughly descriptive at best; in fact, it is exceedingly undesirable, and should not be accepted in the nomenclature of metallography. However, because it has been in common usage for such a long time, it is used in U. S. Bureau of Mines Technical Paper No. 290 to include all kinds of metallic and non-metallic inclusions that cause difficulty in polishing and machining aluminum-alloy castings. Hard spots in aluminum-alloy sand castings are well known to founders, and certain kinds of hard spots are frequently found in aluminum-base die castings.

Although many representative aluminum-alloy founders by care in practice have been able practically to eliminate hard spots and resulting trouble when aluminum-alloy castings are machined, others still have periodic difficulties because of this defect. A number of foundrymen have suggested at various times that the Bureau of Mines investigate hard spots, put the available information on record, and suggest preventive methods. Such an investigation was undertaken and carried out in connection with the Bureau's work on casting losses in aluminum-alloy foundry practice. The present paper is published as a contribution to the literature of aluminum-foundry practice and as a guide to founders in preventing scrap losses from hard spots in castings. Address the Bureau of Mines, Washington, D. C.

Highways A1-22. FLEXURAL STRENGTH OF PLAIN CONCRETE. See *Cement and Other Building Materials A4-22.*

Iron and Steel A4-22. STUDY OF ALLOY STEELS. The results of studies in the experimental production of certain alloy steels are given in Bulletin 199, by H. W. Gillett, chief alloy chemist, and E. L. Mack, assistant alloy chemist, which has just been published by the U. S. Bureau of Mines.

The production of small heats of alloy steels on an experimental scale is often desirable in beginning the study of new alloy steels before large amounts of expensive alloys are used in heats of commercial size. Such small heats can sometimes be made up at crucible-steel plants but few crucible-steel makers care to undertake experimental heats for other firms. Small electric furnaces offer some advantages over crucible furnaces for experimental work, and various types of such furnaces are being successfully used by different firms for such work.

The Bureau of Mines has recently made up experimental heats of alloy steels for the Army and the Navy. The steels for the Army were desired for work on gun erosion, especially as regards the effect of nitrogen on the steel. The request from the War Department for this experimental work was made during the course of the World War and followed the receipt of information from a creditable source that Germany was using uranium steel in the liners of some high-power naval guns. It was stated that uranium stiffens steel at high temperatures, and raises the softening point some 200 deg. cent., so that gun erosion at the end of the Jutland naval engagement was ascribed to the uranium-steel gun liners. Somewhat similar reports had been received as to the use of molybdenum steel.

The ingots made for the Navy were in two series, the first being rolled, heat-treated, and given physical tests by the Bureau of Standards. The second series was made in larger ingots, which were rolled into plates, cut up into smaller plates, and heat-treated to different Brinell hardness numbers by the Halcomb Steel Co. Physical tests of this series under several heat treatments are being made by the Navy.

Some of the points brought out in preparing the steels, particularly as to the recovery of the alloying elements from the various ferroalloys entering the steel, may be of interest and are therefore put on record at this time. The indirect-arc furnace finally used seems also to justify its description.

Detailed information regarding tests made with uranium, silicon, manganese, molybdenum, chromium, vanadium, nickel, copper-nickel, aluminum, zirconium, cerium and boron as alloying agents are given in Bulletin 199, which may be obtained by addressing the Bureau of Mines, Washington, D. C.

B—Research in Progress

The purpose of this section of Engineering Research is to bring together those who are working on the same problem for coöperation or conference, to prevent unnecessary duplication of work and to inform the profession of the investigators who are engaged upon research problems. The addresses of these investigators are given for the purpose of correspondence.

Iron and Steel B4-22. MOLYBDENUM AND OTHER ALLOY STEELS. In the study of molybdenum and other alloy steels being made by Dr. H. W. Gillett at the Ithaca, N. Y., office of the Bureau of Mines, 600 endurance test pieces have been ground and polished to a special mirror finish ready for testing. These bars will keep two endurance machines busy night and day for probably more than a year.

Paints, Varnishes and Resins B3-22. FAILURE OF PAINT AND VARNISH ON EXPOSURE TO WEATHER. During the recent meeting of the American Society for Testing Materials at Atlantic City, there was an extended informal discussion of the mechanism of failure of paint and varnish films on exposure to the weather. One party to the discussion claimed that a paint or varnish film should contain moisture in order to retain its elasticity. The known beneficial effect of baking a varnish film was then cited as being contradictory to this theory that moisture improved the durability of paint or varnish. The importance of the problem makes it appear advisable to study baked varnish films in order to obtain some definite data on the effect of baking. The Bureau of Standards has commenced an investigation in which a series of spar varnishes of varying lengths of oils will be baked on tin panels at different temperatures, and then tested for durability when exposed to the weather.

Steel, Its Treatment and Products B5-22. MINE-DRILL STEEL. A committee, advisory to the U. S. Bureau of Mines and Bureau of Standards, has been formed on the subject of mining-drill steels, their composition, treatment, thermal and mechanical, and reclamation; together with causes of breakage as related to standardization of design and practice, properties, manufacture and preparation, with the object of eliminating waste and delays in mining operations. Several meetings have been held, a preliminary program mapped out, and these Bureaus have made a joint survey of drill-steel practice in the metal mines of some ten western states, obtaining data which will be of use in suggestions as to standardization of design, heat treatment and practice generally as relating to drills and auxiliary mining machinery. Reports of this survey are in preparation.

E—Research Personnel

The purpose of this section of Engineering Research is to give notes of a personal nature regarding the personnel of various laboratories, methods of procedure for commercial work or notes regarding the conduct of various laboratories.

Iron and Steel E1-22. THE BRITISH CAST IRON RESEARCH ASSOCIATION. A pamphlet just received describes the objects of this recently organized association as (1) to promote coöperation among firms engaged in the various allied industries connected with the production and utilization of cast iron in Great Britain, with a view to the establishment of a scheme for scientific and industrial research; (2) the distribution among its members of technical and other information relating to the production, treatment, manufacture and utilization of cast iron. This necessitates the efficient coördination of the existing means of research and their further development.

The work of the Association will include the investigation of problems arising in the manufacture of pig irons, gray-iron castings, malleable-iron castings, semi-steel castings, chilled rolls, cast-iron hollowware, cast-iron pipes, light castings, etc., in such a way as to cover and include all branches of the cast-iron industry. Successful and economic production of these materials is very intimately bound up with the questions of melting, annealing, furnace design and construction, refractory materials, molding sands, the economical utilization of fuel, and the engineering aspect of foundry work. All these and other subsidiary operations will be dealt with by the Association, either directly, or in collaboration with other research bodies.

For further information address Mr. H. B. Weeks, F.I.C., care of Vickers, Ltd., Barrow-in-Furness, England.

CORRESPONDENCE

CONTRIBUTIONS to the Correspondence Department of MECHANICAL ENGINEERING are solicited. Contributions particularly welcomed are discussions of papers published in this journal, brief articles of current interest to mechanical engineers, or comments from members of The American Society of Mechanical Engineers on activities and policies of the Society in Research and Standardization.

The Accuracy of Boiler Tests

TO THE EDITOR:

The writer desires to express his gratification that the main object of his Spring Meeting paper on The Accuracy of Boiler Tests has been so amply fulfilled by the masterly discussion of leading authorities. This discussion has been so thorough that it is impossible to reply to it fully without writing another paper.

Replying to Mr. Bell, the writer prefers to have all test reports accompanied by heat balances. They indicate the value of the reports. Serious unbalance shows inefficiency of observation or of operation. Reports of a series of tests wherein the "unaccounted for" was consistently over 20 per cent were recently submitted to the writer, who had reason to believe that much more coal was leaving the fire in a non-gaseous state than was proper and than the ash analysis suggested.

The value of the heat balance as a statement of what has happened to the heat is really not open to question. But many engineers who are not skilled in boiler testing are impressed with the heat balance; and the writer therefore feels justified in repeating that it is not a *balance* and that it adds nothing to the accuracy of the test. It is usually less of a check on the efficiency than on the other items.

The writer appreciates Mr. Bradshaw's remarks on the determination of dust in blast-furnace gas, and its similarity to the determination of water dust in steam. That the velocity of the gas sample entering the tube should be the same as that of the bulk agrees with the writer's views; as also does the use of a sampling tube pointing upstream.

Mr. Burke suggests using the draft loss through the fuel bed to determine the condition of the fire at start and stop. This is a step in the right direction; but the presence of clinker must be reckoned with, and variation in the size of coal in some cases, as these would increase the draft loss for the same amount of fuel in the bed.

His caution about the rate of feed at start and stop is very important. It is probable that many engineers would be surprised at the error which can result in this way. It is more accurate to calculate the deficiency at the end of the run than to pump rapidly up to the mark as the test is coming to an end.

The importance of having conditions as well as quantities the same at both ends of the trial cannot be stressed too much.

The difficulty of getting even an approximate idea of the proportion of fuel sent to the ashpit may be the cause of considerable error in the heat balance, as has also been pointed out by Mr. Bell.

It is questionable whether it would be agreeable to rate all superheaters at 10 sq. ft. to the horsepower. Should Mr. Bell's Radiant Heat Absorption Superheater be rated at this figure?

Replying to Mr. Davidson, it cannot be too strongly urged that the present method of reporting boiler tests is not strictly honest. It is not even sufficient to say that the power used by auxiliaries should be noted and that any one interested can find the net efficiency, or that conscientious engineers always instruct their clients to pay no attention to the efficiencies they have reported. If a test report does not openly show the net efficiency, it is not a straightforward report. It may be that a simple system does not show as high an efficiency as a more elaborate one, while the more elaborate one loses more than the apparent gain by the power required to operate it. Both efficiencies should be clearly shown thus:

	Simple System	Elaborate System
Gross efficiency	75.0	79.0
Net efficiency after deducting power consumed by parasites	74.0	72.0

We then clearly see that the more elaborate system is more efficient in combustion, heat transfer or what not; but that in the final analysis the simpler system is the more economical. It is to be hoped that the new Boiler Test Code will prescribe a form of report in which these facts are not obscured.

Replying to Mr. Funk, the writer's reasoning on the reliability of steam sampling is based very largely on experience with other apparatus. Experimental investigation is highly desirable.

Messrs. Hirshfeld, Berry, Thompson, and Carter have done a valuable work in pointing out that many lawsuits have followed this false conception of accuracy. These would be avoided by our admitting that we cannot guarantee the accuracy of boiler trials to be within some given percentage, and then setting definite tolerances to be allowed. This naturally refers to commercial tests. Research tests have little or nothing to do with guarantees, and nothing to do with lawsuits.

Research tests are made at home, so to speak, and under conditions which cannot usually be duplicated profitably with commercial tests. The writer believes that when these gentlemen, who have devised and frequently operate highly developed testing methods and means in the same plants, place the accuracy of these precision tests at about plus or minus 1.5 per cent, they virtually confirm the writer's proposed allowance of plus or minus 3 per cent on a commercial test. He does not believe it is generally recognized that such research tests may be out 1 per cent.

There is another kind of research test, the kind made by the ambitious engineer of the small plant, without much apparatus or abstruse knowledge. The writer recently saw a case where such an engineer had raised the "actual" evaporation per pound of coal "as fired" about 15 per cent as averaged from a large number of tests. These tests were scarcely worth the name and probably carried large errors, but the fact remains that his employer is buying less coal than he used to.

The use of the boiler as a gas-flow meter in connection with the pressure drop through the fuel bed is excellent in checking the thickness of the fuel bed, and may reduce this error very materially.

The writer did not in his Par. 17 refer to drying the coal *to be fired*, but to drying samples to ascertain the moisture while the test was in progress.

He entirely agrees with Mr. Kreisinger that the really important thing is not a single test, but a load-efficiency curve, drawn through a group or groups of tests. The accuracy of such a curve may easily be within 1 per cent. But such multiple testing is not always possible with commercial trials.

To emphasize the care necessary in taking samples, it may be well to mention that the coal analyzed in the laboratory is of the order of 1/10,000,000 of the coal burned and that about 1/100,000,000 of the flue gases are analyzed. The serious feature of errors in the heating value of the fuel is that they are in no wise reduced by increasing the duration of the test. Unless the heating-value error can be made very small, a point is soon reached where little is gained by increasing the duration of the trial. Mr. Kreisinger's broad discussion on the reliability of the heating value is rendered the more authoritative by his long experience.

The writer feels prompted to add the following recent analyses of fuel oils:

	B.t.u. per Pound Boiler test number		
Analyst	4	7	8
A	..	..	17,803
B	..	..	18,600
C	17,081	17,261	17,199
D	..	17,295	..
E	..	16,980	..
F	..	..	..
G	17,334	16,968	17,256

In test No. 4, analyst G is 1.48 per cent above analyst C, while in No. 7, C is 1.72 per cent above G. In No. 8 they agree very closely, but analyst B gets a result 2.35 per cent above C.

The "boiler horsepower" dies slowly. If we were to express the load in all future test reports as B.t.u. per sq. ft. of heating surface per hour as Mr. Kreisinger suggests, as well as in "percentage of rating," it is probable that we could become reconciled to the loss of the boiler hp. more quickly.

Mr. Moultrop mentions handhole leakage as one of the unknowables. The writer believes that during the trials made about 25 years ago by the British Admiralty to determine the relative merits of Belleville, Scotch and other boilers, the water loss in the Belleville ran about 5 per cent of the evaporation in some instances, but this is only from memory.

He does not agree with Mr. Moultrop that the manufacturer and customer should settle upon a tolerance. The first manufacturer who does this is very liable to be looked upon as having little faith in his own product. Such tolerances must be settled and recommended by the Boiler Test Code Committee if at all, and it is to be hoped that this will be done.

The writer is glad to find Mr. Tenney in agreement with him that all conditions surrounding the test should always be reported. This is not done very often, and some important conditions are scarcely ever reported. It is obvious that a certain efficiency attained with the coal Mr. Tenney burns might be much more creditable than a little higher efficiency with a much better coal.

In reply to Mr. Vennum, the present boiler efficiency shows what proportion of the heat in the fuel was used to make steam, but it is reasonable that an efficiency should also be reported which shows how much heat was used of that which it was possible to use. This proposed efficiency would be mainly for research purposes, not for commercial tests.

Mr. Vennum says that we want to know what proportion of the heat in the fuel is made available for mechanical use, and it is obvious that this is just what our present efficiency does *not* show us, until after we have deducted the auxiliaries.

Speaking generally, the discussion confirms the writer's opinion that the inaccuracies at present inherent in commercial boiler testing are sufficient to warrant the introduction of tolerance in the performances of guarantees as a recognized engineering custom. In research testing the errors can be reduced to about one-half of those of commercial tests, and to still less than this as the number of the tests is increased and rendered into a load-efficiency curve.

Alfred Cotton.

St. Louis, Mo.

Compounding the Combustion Engine

To the Editor:

Referring to the discussion of a paper by Mr. E. A. Sperry on Compounding the Combustion Engine which appeared in the August number of Mechanical Engineering, I would like to submit the following comments.

I have carefully followed the subject in question for some years and wish to say that while Mr. Sperry's contribution to the art should by no means be minimized, it should not be judged by the paper he presented nor by the extravagant claims and references he makes in his closure. The fact that he started considerable discussion of this promising subject among the engineers concerned, however, is evidence enough that he "is to be commended for his research along this line," as Mr. J. C. Shaw expressed it.

In his paper Mr. Sperry utterly disregarded established technical terminology and employed such expressions as "persisting" pressures, "hanging on to pressures," "chilled perimeter," "modern two-stage method of compression," etc. These may mean something to him, but they have been rightfully objected to by his commentators, Mr. J. C. Shaw at the meeting, and Mr. James Richardson in (London) *Engineering*.

If Mr. Sperry's "special adaptation of cushioning," meaning the compression of part of the exhaust gases trapped in the low-pressure cylinder (which he claims as new and which Diesel used on his compound engine in 1897), was adopted to restore them to a temperature equal to that of the gases coming from the high-pressure cylinder, then he stopped too soon when he equalized the pressures, because at that time there is of course still over 1000 deg. fahr. difference in favor of the incoming gases.

In his closure he proceeds to use the same misleading language: "The compound combustion cylinder handles a great many times the weight of air compared with the simple Diesel, not only many times the weight of air but many times the fuel with more complete combustion than in any simple engine." Later it develops that "a great many times" means "from four to six times," which is rather modest for such an ambiguous term, but the "more complete combustion" is left on the conscience of the inventor to prove.

I also question his assertion that a "compound engine of any kind" invariably develops back pressure on the piston" of the next higher stage. Steam engines do and Sperry's engine does, and that is the only thing that may make them akin; but, generally speaking, internal-combustion compounding and steam-engine compounding have nothing in common, not even back pressure, since that is avoidable in the combustion engine.

Mr. Sperry's discussion of reasons for using or not using a crosshead does not bear on the subject of compounding. However, he has only to visit the Brooklyn Navy Yard to see a 3000-hp. Diesel submarine engine of 21 in. bore without any crosshead in it.

His dismissal of "shocks, strains and heat troubles" as being "on a par with many other of the imaginary troubles," or his "there is no such thing as a previous compound engine to compare with," lead me to ask you to reprint for his information, as well as for that of many other engineers, the appended translation of Dr. Diesel's statement regarding his own efforts in compounding, published in 1913.

In conclusion, I would say that in spite of the defects of Mr. Sperry's paper, grave as they are, and the fact that he did not invent "compounding," he claims that he built an engine that runs economically, and that is an achievement well worth claiming.

Washington, D. C. E. C. Magdeburger.[1]

[The translation of Dr. Diesel's statement regarding his efforts in compounding, to which Mr. Magdeburger refers in his communication, immediately follows.—Editor.]

The Compound Engine[2]

The German patent D.R.P. 67,207 of February 28, 1892, contained a figure (Fig. 73) of the compound engine. From the text of this patent application the following is quoted:

"Compression of air as well as the expansion of the exhaust gases could be undertaken in steps, as in a representative construction shown in Fig. 73. In this sketch the valves are shown only schematically. The housing, the connecting rod, the flywheel, etc., are omitted. In such a construction two internal-combustion cylinders *C* are perfectly identical with the cylinder of any one-cylinder motor. These cylinders are connected by means of mechanically operated valves *B* on the two sides of one larger middle cylinder *B;* also mechanically operated valves *A* connect the internal-combustion cylinders with the air container *L*. The new process with this construction is as follows:

"Piston *Q* moving upward draws in atmospheric air through valve *d*, compresses it up to a certain pressure, and delivers it through valve *g* into the air container *L*. The lower part of the middle cylinder henceforth serves only as an air compressor to precompress the air necessary for combustion. At *g* are water-injection nozzles through which it is possible to inject water during the precompression. The cycle can be run with or without water injection. The cycle in the cylinders *C* is exactly the same as in the single-cylinder motor already shown, except that the piston *P* moving downward draws in the air not from the atmosphere but out of the air container *L* where the air is already under certain pressure. Moving upward the piston *P* completes the second stage of the compression up to a given pressure. Both dead-center positions of piston *P* are shown dotted and marked with figures 1 and 2. After that, piston *P* again goes downward with oil being injected continuously for a certain part of the stroke. In the position 3 of the piston the oil injection stops and the gases expand further. When the piston is in the lower position 1 the valves *b* open. The piston *Q* at that moment is exactly opposite since the cranks are 180 deg. apart. Continuing, piston *P* goes up and piston *Q* down, and further expansion of the exhaust gases up to the volume of the cylinder *B* takes place. After that the valve *b* closes and *p* opens, so that with the next upstroke of the piston *Q* the exhaust gases can be expelled into the atmosphere through valve *F*."

Already in my paper delivered in Kassel in June, 1897, I maintained that in a compound engine the thermodynamic efficiency will be very much higher than in a single-cylinder engine. The constructional drawings of such a compound engine were made to my order by Mr. Nadrowski, of

---

[1] Aide on Diesel Engines, Bureau of Engineering, Navy Department. Mem. Am.Soc.M.E.

[2] Translation of a chapter from a book by Dr. Rudolf Diesel, entitled The Development of the Diesel Engine (Die Entstehung des Diesel Motors), Julius Springer, Berlin, 1913

Berlin, during the year 1894-1895. This engineer later came to Augsburg where he improved these drawings as the results from the single-cylinder engines had indicated. The first detail drawings for the frame and bedplate reached the pattern shop late in December 1895. Inasmuch as the tests on the single-cylinder engines had been producing new results continuously, the building of a compound engine was not rushed. Several patterns were completed at the close of 1896 and it took another six months before the assembly could begin. My assistant, R. Pawlikowski, was entrusted with the supervision of the assembly and the conducting of tests which began in September 1897. He was assisted in that work by Messrs. Böttcher and Reichenbach whenever these gentlemen were not otherwise employed.

The construction of details of the compound engine, as far as the internal-combustion cylinder is concerned, is exactly the same as that of the single-cylinder and since the whole construction never attained practical importance I do not think it of sufficient interest at this time to publish the detail drawings. However Figs. 74 and 75 are photographic reproductions of both sides of this engine, and 76 shows it on the test stand next to the single-cylinder engine.

The dimensions of this engine were as follows: High-pressure cylinder bore, 200 mm.; low-pressure cylinder bore, 510 mm.; stroke for both cylinders, 400 mm.; connecting-rod diameter, 80 mm.; number of revolutions, 150 per minute.

The tests themselves can be now summarized. First of all they showed that the air in the intermediate container between the low-pressure and high-pressure cylinders cooled off too quickly, and a steam-heated coil was built in as shown in Fig. 77, following which at the end of September, 1897, the first ignitions took place. Fig. 78 shows the series of the first high-pressure diagrams. After that the air out of the low-pressure cylinder was taken to the high-pressure cylinder direct without first going through the intermediate air container. This showed the desired result and the heating coil for the precompressed air was done away with. After about eight minutes of running, good smokeless and regular ignitions in the high-pressure cylinder were produced without preheating of the air with steam. Preheating of the air or of the engine itself henceforth would be only necessary when starting similar to the preheating of the cylinders in steam engines.

Later the engine ran quite regularly, as shown by the diagram Fig. 79, which is a superimposition of 30 ignitions. Soon, however, different mistakes showed up on the engine: the high-pressure cylinders got very hot; the cooling water boiled; the uncooled piston knocked; the transfer valves warped, etc. We succeeded in overcoming these mistakes, and for hours the engine ran on no load without any mishap. The diagram, Fig. 80, is an example of this. Here the air out of the compressor cylinder was delivered direct into the high-pressure cylinder without going through the intermediate air container. The tests showed a considerable pressure drop at the point of transfer of the exhaust gases from the high-pressure into the low-pressure cylinder. To lessen this drop a part of the exhaust gases was trapped in the low-pressure cylinder and compressed up to 12 to 14 atmospheres, so that at the moment of opening of the transfer valve no drop in pressure could take place. This result was of course compensated for by a considerable negative work on the diagram. Fig. 81 in the upper right-hand corner, shows the average original diagrams taken on November 18, 1897. The average pressure of the compressor diagram (lower side of the low-pressure cylinder) was 2.40 kg. per sq. cm. The average pressure of the high-pressure cylinder to the right (the cylinder to the left was not in working order) was 19.4 kg. per sq. cm. The average pressure of the low-pressure cylinder was 2.71 kg. per sq. cm.

The main diagram shows the above-mentioned diagrams Rankinized, the lower part showing the details of actual construction of the diagram. In the table to the left the final results are given whereby all average pressures are referred to the upper part of the low-pressure cylinder to compare it directly with the results of a single-cylinder motor of similar dimensions. The process of figuring can be easily checked with the dimensions of the engine cylinders as given above.

The original diagrams in this manner give an average pressure of 4.39 kg. per sq. cm. The Rankinized diagram gives an average pressure of 4.48 kg., that is, only two per cent higher, hence an error of only two per cent. In this main diagram an ideal diagram is also shown which could be produced in the middle cylinder alone when precompression and after-expansion would not be employed, and that comparison shows the most disappointing result, namely, that in a compound engine only 54.4 per cent of the ideal diagram was converted into useful work.

The test results showed a no-load fuel consumption of 499 grams per horsepower-hour, which quite explains the inefficiency of the diagram.

The most important loss of the whole process is the heat loss through the transfer of the exhaust gases from the high-pressure into the low-pressure cylinder. At this point, as it is shown on Fig. 73 schematically, there was not a single transfer valve but two valves, one close to the high-pressure cylinder and the other close to the low-pressure cylinder, in order to isolate the considerable volume between those two cylinders from the cylinder volumes proper. These two valves were cooled and the heat absorbed by the cooling water of the valves could be measured very accurately. This heat loss to the cooling water of the valve amounted on one side of the engine to 5.9 per cent of the total available heat of the oil, and on both sides, therefore, to 11.8 per cent, or about half of the heat that was transferred into useful work in a single-cylinder engine. Each of these four valves absorbed about three per cent in round figures of the total available heat. How much heat was lost at the same time to the cooled walls of the transfer ducts themselves and how much besides was taken away by radiation, could not be definitely measured. However, it must be assumed that these losses were considerable, due to the fact that the surfaces of the ducts were large and were energetically cooled. These enormous losses could not be brought into harmony with the computed results of the heat transferred through walls according to the prevailing methods at that time. Quite naturally an effort was made to estimate beforehand these losses based on the prevailing assumptions of the coefficient of heat transfer, but these computations produced such small values for these losses that I did not worry about them. Zeuner, with whom I discussed this point long before the actual tests were conducted, did tell me that in his opinion considerable surprises might be expected with gases at such high velocities, but that was only a matter of opinion that he could not substantiate with figures. The results proved that these computations were a failure. This single loss was so great that practical application of compounding could not be thought of for this reason alone. In view of this fact it is probably superfluous to describe the other numerous losses encountered in tests which were due to the transfer of air out of one cylinder into the other both during its compression and expansion. The total losses doomed the compound principle. My great hopes to considerably improve the heat utilization of the single-cylinder engine had to be given up, however much I disliked to do it.

The above brief description of these tests and the scientific explanation of their failure will, I hope, save others from similar disappointments.

Second Revision of A.S.M.E. Boiler Code, 1922

A HEARING is held by the Boiler Code Committee at least once in four years, at which all interested parties may be heard, in order that such revisions may be made as are found to be desirable, as the state of the art advances. The year 1922 becomes the period of the second revision, the first revised edition of the Boiler Code having been issued in 1918. The Boiler Code Committee plans to hold a Public Hearing in connection with the next Annual Meeting of the Society in December, 1922, to which the membership of the Society and everyone interested in the steam-boiler industry will be invited and where they may present their views.

In the course of the Boiler Code Committee's work during the past four years, many suggestions have been received for revisions of the Power Boiler Section of the Code, as a result of the interpretations issued and also of the formulation of the Locomotive Boiler and the Miniature Boiler Codes. In order that due consideration might be accorded to these recommendations, the Committee began in the early part of 1921 to devote an extra day at each of its monthly meetings to the consideration of the proposed revision. As a result of this many of the recommendations have been accepted and revisions of the paragraphs formulated.

In connection with the revision work, the lack of rules and specifications relative to pipe, pipe material and fittings for use in connection with steam boilers up to the flanges for the connection of the first valves, has been apparent. The Committee has endeavored, at the urgent request of many manufacturers, to supply this lack by rules and specifications which have been prepared in coöperation with the American Society for Testing Materials. These rules and specifications are here published and it is the request that they be fully and freely discussed so that it may be possible for any one to suggest changes before the rules are brought to final form and presented to the Council for approval. Discussions should be mailed to C. W. Obert, Secretary to the Boiler Code Committee, 29 West 39th St., New York, N. Y., in order that they may be presented to the Boiler Code Committee for consideration.

RULES FOR PIPE, PIPE MATERIAL AND FITTINGS USED ON STEAM BOILERS

X-1 Piping and Fittings. The piping and fittings used on boilers up to the flanges for the connection of the first valves from the boiler on steam outlets, feed lines and blow-off lines shall conform to the rules given in *X-1* to *X-6*, and it is desirable that all piping, valves and fittings used on steam and exhaust lines, including the vacuum system and drain lines; all water lines, including boiler-feed suction and discharge lines; and all boiler blow-off lines shall conform to them.

X-2. Steam Pipe. Piping for steam mains carrying saturated or superheated steam may be of welded or seamless pipe made of wrought iron or steel. For sizes above 3 in. in diameter the steel

pipe shall be of open-hearth steel. All pipes shall be straight and free from blisters, cracks, laminations and other injurious defects. Liquor marks and lap-seam lines incidental to the manufacture of pipe will not be considered defects. Each length of pipe is to be inspected separately for defects on the inside and outside, noting particularly the character of the cross-section when cutting off crop ends. Pipe up to 3 in. in diameter may be butt-welded or lap welded while that above 3 in. in diameter shall be lap-welded. Pipe material shall correspond with that required by the specifications of wrought-iron and steel pipe included in Par. *X-9,* et seq.

X-3. Thickness of Steam Pipe. In determining the thickness to be used for pipes at different pressures and for temperatures not exceeding 700 deg. fahr. the following formula is to be used:

$$P = \frac{2\ S(t - 1/16)}{D}$$

where

P = the working pressure in lb. per sq. in. above atmosphere
t = thickness of wall in inches
D = inside diameter of pipe in inches
S = 3500 lb. per sq. in. for seamless steel pipe
= 3200 lb. per sq. in. for lap-welded steel pipe
= 2500 lb. per sq. in. for butt-welded steel pipe
= 2500 lb. per sq. in. for lap-welded iron pipe
= 2000 lb. per sq. in. for butt-welded iron pipe
= 2000 lb. per sq. in. for brass pipe
= 2000 lb. per sq. in. for copper pipe.

X-4. Feed Lines. High-pressure hot-water and cold-water lines may be made of welded or seamless pipe of wrought-iron or steel as called for under *X-2.* Where the water contains corrosive material or air, brass or copper tubing may be used. In determining the thickness of water pipe the following formula will be used:

$$P = \frac{2\ S\ (t - 3/32)}{D}$$

where: P = water pressure in lb. per sq. in.
t = thickness of pipe in inches
D = inside diameter of pipe in inches
S = 2625 lb. per sq. in. for seamless steel pipe
= 2400 lb. per sq. in. for lap-welded steel pipe
= 1875 lb. per sq. in. for butt-welded steel pipe
= 1875 lb. per sq. in. for lap-welded iron pipe
= 1500 lb. per sq. in. for butt-welded iron pipe
= 1500 lb. per sq. in. for brass pipe
= 1500 lb. per sq. in. for copper pipe.

Where brass pipe is desired for finish or for any other reason it may be used. The brass and copper pipes used shall correspond to the specifications given under Pars..... and the brass pipe shall be half-annealed in order to leave it in proper condition for use in feed-water piping.

X-5. Blow-off Piping. Blow-off pipe is to be of extra strong size and to be made of genuine wrought iron or steel as preferred.

X-6. Pipe Bends. Pipes when bent may be made of steel or wrought iron and after bending are to be free from buckles and blisters and practically circular in cross-section. They are to be bent before being threaded or flanged, and where flanged they are to be refaced to dimensions so that they may be bolted or faced without forcing. Where possible, the tangent length of pipe at the end of each bend should be of a length equal to at least twice the nominal diameter of the pipe, although tangents may be used with lengths which are equal to the nominal diameter of the pipe. The advisable radius to which pipe should be bent should be five or six times the nominal diameter of the pipe, although pipe may be bent to a radius equal to four times the diameter of standard pipe and three and one half times the diameter for extra strong pipe up to 12 in. The thickness of the pipe is to be determined by the formula given in *X-3.* The boiler-feed-line bends are to conform with the above, while for blow-off lines the rules are to be applied to extra strong pipe.

SPECIFICATIONS FOR WELDED AND SEAMLESS STEEL PIPE

X-7. These specifications cover "standard" and "extra strong" welded and seamless steel pipe, but not "double extra strong" pipe. Pipe ordered under these specifications are intended for bending, flanging and other special purposes.

I—Manufacture

X-8. (*a*) The steel for welded pipe shall be of soft weldable quality made by the bessemer or open-hearth process. The steel for seamless pipe shall be made by the open-hearth process.

(*b*) Welded pipe 3 in. or under in nominal diameter may be butt-welded, unless otherwise specified. Welded pipe over 3 in. in nominal diameter shall be lap-welded.

II—Chemical Properties and Tests

X-9. Open-hearth steel shall conform to the following requirement as to chemical composition:

Phosphorus....................not over 0.05 per cent

III—Physical Properties and Tests

X-10. (*a*) The material shall conform to the following minimum requirements as to tensile properties:

	Welded		Seamless
	Bessemer	Open-hearth	Open-hearth
Tensile strength, lb. per sq. in.	50000	45000	48000
Yield point, " " "	30000	25000	26500
Elongation in 8 in., per cent	18	20	18

(*b*) The yield point shall be determined by the drop of the beam of the testing machine.

X-11. (*a*) Welded pipe shall be tested at the mill to the hydrostatic pressures specified in Table I.

TABLE I HYDROSTATIC PRESSURES FOR WELDED STEEL PIPE
(Black and galvanized. Pressures expressed in pounds per square inch.)

	"Standard" Pipe			"Extra Strong" Pipe		
Size, (nominal inside diameter), in.	Weight of pipe per linear foot, threaded and with couplings, lb.	Butt-weld	Lap-weld	Weight of pipe per linear foot, plain ends, lb.	Butt-weld	Lap-weld

12.......	45.00	...	600	....	....	....
12	50.71	...	800	65.42	....	1000

For pipes over 12 in. in inside diameter, the test pressures should be calculated by the formula $P = 2St/D$, in which P = pressure in pounds per square inch; S = fiber stress = 12,000 lb. per sq. in.; t = thickness of wall in inches; D = inside diameter in inches.

(*b*) Seamless pipe shall be tested at the mill to hydrostatic pressures not exceeding that required by the formula:

$$P = \frac{2\ S\ t}{D}$$

in which P = pressure in pounds per square inch; S = allowable fiber stress = 16,000 lb. per sq. in.; t = thickness of wall in inches; and D = inside diameter in inches.

X-12. (*a*) For lap-welded pipe over 2 in. in diameter, a section of pipe 6 in. long shall be flattened between parallel plates until the distance between the plates is one-third the outside diameter of the pipe with the weld located 45 deg. from the line of direction of the applied force, without developing cracks.

(*b*) For butt-welded pipe over 2 in. in diameter, a section of pipe 6 in. long shall be flattened between parallel plates until the distance between the plates is 60 per cent of the outside diameter of the pipe with the weld located 45 deg. from the line of direction of the applied force, without developing cracks.

X-13. For pipe 2 in. or under in diameter, a sufficient length of pipe shall withstand being bent cold through 90 deg. around a cylindrical mandrel the diameter of which is 12 times the nominal diameter of the pipe, without developing cracks at any portion and without opening the weld.

X-14. (*a*) Test specimens shall consist of sections cut from a pipe. They shall be smooth on the ends and free from burrs.

(*b*) Tension test specimens shall be longitudinal.

(*c*) All specimens shall be tested cold.

X-15. One of each of the tests specified in Pars. *X-10*, *X-12* and *X-13* may be made on a length in each lot of 500 or less, of each size. Each length shall be subjected to the hydrostatic test.

X-16. If the results of the physical tests of any lot do not conform to the requirements specified in Pars. *X-10*, *X-12* and *X-13*, retests of two additional pipes shall be made, each of which shall conform to the requirements specified.

IV—Workmanship and Finish

X-17. For pipe $1^1/_2$ in. or under in inside diameter, the outside diameter at any point shall not vary more than $^1/_{64}$ in. over nor more than $^1/_{32}$ in. under the standard size. For pipe 2 in. or over in inside diameter, the outside diameter shall not vary more than 1 per cent over or under the standard size.

X-18. Unless otherwise specified, pipe shall conform to the following regular practice:

(*a*) Each end of standard welded pipe shall be threaded.

(*b*) Extra strong welded pipe and standard and extra strong seamless pipe shall be furnished with plain ends.

(*c*) All threads shall be in accordance with the American Standard and cut so as to make a tight joint when the pipe is tested at the mill to the specified internal hydrostatic pressure. The variation from the standard, when tested with the standard working gage, shall not exceed a maximum of one and one-half turns either way.

(*d*) Each length of threaded pipe shall be provided with one coupling, having clean-cut threads of such a pitch diameter as to make a tight joint. Couplings may be made of wrought iron or steel.

X-19. The finished pipe shall be reasonably straight and free from injurious defects. All burrs at the ends of the pipe shall be removed.

V—Inspection and Rejection

X-20. The inspector representing the purchaser shall have free entry, at all times while work on the contract of the purchaser is being performed, to all parts of the manufacturer's works which concern the manufacture of the pipe ordered. The manufacturer shall afford the inspector, free of charge, all reasonable facilities to satisfy him that the pipe are being furnished in accordance with these specifications. All tests and inspection shall be made at the place of manufacture prior to shipment, unless otherwise specified, and shall be so conducted as not to interfere unnecessarily with the operation of the works.

Each length of pipe which develops injurious defects in shop working or application will be rejected, and the manufacturer shall be notified.

SPECIFICATIONS FOR WELDED AND SEAMLESS WROUGHT-IRON PIPE

X-21. These specifications cover "standard" and "extra strong" welded wrought-iron pipe, but not "double extra strong" pipe.

X-22. All pipes to be used on locomotives and cars shall be of coiling or bending quality.

I—Manufacture

X-23. (*a*) The iron shall be made from muck bars, made from puddled pig iron, free from any admixture of iron scrap or steel.

(*b*) All pipe 3 in. or under in nominal diameter may be butt-welded, unless otherwise specified. All pipe over 3 in. in nominal diameter shall be lap-welded.

X-24. *Iron Scrap.* This term applies only to foreign or bought scrap and does not include local mill products, free from foreign or bought scrap.

II—Physical Properties and Tests

X-25. (*a*) The material shall conform to the following minimum requirements as to tensile properties:

Tensile strength, lb. per sq. in.	40,000
Yield point, lb. per sq. in.	24,000
Elongation in 8 in., per cent	12

(*b*) The yield point shall be determined by the drop of the beam of the testing machine. The speed of the cross-head of the machine shall not exceed $^3/_4$ in. per minute.

X-26. All pipe shall be tested at the mill to the hydrostatic pressures specified in Table I.

X-27. A section of pipe 6 in. in length shall be flattened until broken by repeated light blows of a hammer or by pressure; the fracture developed shall have a fibrous appearance.

X-28. For pipe 2 in. or under in diameter, a sufficient length of coiling or bending pipe shall withstand being bent cold through 90 deg., around a cylindrical mandrel the diameter of which is 15 times the nominal diameter of the pipe, without developing cracks at any portion and without opening the weld.

X-29. (*a*) Test specimens shall consist of sections cut from a pipe. They shall be smooth on the ends and free from burrs.

(*b*) Tension-test specimens shall be longitudinal.

(*c*) All specimens shall be tested cold.

X-30. One of each of the tests specified in Pars. *X-25*, *X-27* and *X-28* may be made on a length in each lot of 500 or less, of each size. Each length shall be subjected to the hydrostatic test.

X-31. If the results of the physical tests of any lot do not conform to the requirements specified in Sections *X-25*, *X-27 and X-28*, retests of two additional pipes shall be made, each of which shall conform to the requirements specified.

III—Workmanship and Finish

X-32. (*a*) For pipe $1^1/_2$ in. or under in inside diameter, the outside diameter at any point shall vary not more than $^1/_{64}$ in. over nor more than $^1/_{32}$ in. under the standard size. For pipe 2 in. or over in inside diameter, the outside diameter shall vary not more than 1 per cent over or under the standard size.

X-33. Unless otherwise specified, pipe shall conform to the following regular practices:

(*a*) Each end of standard pipe shall be threaded.

(*b*) Extra strong pipe shall be furnished with plain ends.

(*c*) All threads shall be in accordance with the American Standard and cut so as to make a tight joint when the pipe is tested at the mill to the specified internal hydrostatic pressure. The variation from the standard, when tested with the standard working gage, shall not exceed a maximum of one and one-half turns either way.

(*d*) Each length of threaded pipe shall be provided with one coupling, having a clean-cut thread of such a pitch diameter as to make a tight joint. Couplings shall be of wrought iron.

X-34. The finished pipe shall be reasonably straight and free from injurious defects. All burrs at the ends of the pipe shall be removed.

IV—Inspection and Rejection

X-35. The inspector representing the purchaser shall have free entry, at all times while work on the contract of the purchaser is being performed, to all parts of the manufacturer's works which concern the manufacture of the pipe ordered. The manufacturer shall afford the inspector, free of charge, all reasonable facilities to satisfy him that the pipes are being furnished in accordance with these specifications. All tests and inspection shall be made at the place of manufacture prior to shipment, unless otherwise specified, and shall be so conducted as not to interfere unnecessarily with the operation of the works.

X-36. Each length of pipe which develops injurious defects in shop working or application will be rejected, and the manufacturer shall be notified.

Koninklijk Instituut van Ingenieurs Celebrates 75th Anniversary

The congratulations of The American Society of Mechanical Engineers are extended to the Koninklijk Instituut van Ingenieurs which celebrated its seventy-fifth anniversary on September 8, 1922. A commemorative medal of this anniversary, which was presented the Society, bears on one side the inscription of the Institute and on the other 1847–1922 To the American Society of Mechanical Engineers.

Our Future Lumber Supply—A Challenge to Engineers

THE United States Forestry Service is authority for the statement that at the present rate of lumbering, the forests of the United States will disappear in between fifty and sixty years. The full significance of this situation challenges the attention of the engineer, who best knows the power and irrigation needs of the country and who understands the dependence of water power and water supply upon forest maintenance.

Charles H. MacDowell

Furthermore the engineer is directly interested in the maintenance of a supply of timber for construction, mining and maintenance purposes. He wants this timber produced in sections tributary to efficient transportation and near consuming points, that its cost may be kept within reasonable limits. He knows that the timber he is now using comes a longer distance and bears an average transportation charge much higher than it did a few years ago. As he looks ahead, he anticipates still higher costs, greater transportation difficulties and a definite shortage of supply. As his training is more impersonal than that of the business man, as he deals with known facts and actual materials, as he is not an opportunist dealing mostly with the present, he is naturally concerned over the problems of the future and gives thought to their solution before they become acute.

He knows that efficient, low-cost mining of fuel and other materials is favorably influenced by a supply of cheap timber. He appreciates that railway sleepers, piling and bridge timbers must constantly be renewed, that other old construction must be kept usable and that new work will call for more and more timber notwithstanding the increasing use of steel, concrete, brick, tile and stone. He is informed on the wood-pulp needs of the country. He studies the wasteful, improvident methods of the past in tillage clearing, in lumbering and in swamp reclamation—and its continuance in many sections today. He reads almost daily of vast damage to growing timber from forest fires, often kindled by careless campers or hate-everybody vandals, and he reaches the conclusion that a tree has little present-day standing in its community, that the public generally has small conception of the service the tree has rendered and must continue to render, if all is to go well. He knows that we are destroying and not replanting and he appreciates where that policy leads to.

Upon a realization of the responsibility of the engineering profession, the American Engineering Council appointed a Committee on Reforestation which has studied the situation and is working out a policy. The problem is severe and has many ramifications leading into the social, economic, and legislative phases which demand that, to be effective, the Committee must coöperate fully with other bodies who have spent much effort on the subject. All of this requires time to accomplish thoroughly. In the meantime, however, the Forestry Service has the facts and statistics and the engineering profession can immediately assist in their publication and interpretation to the public.

The engineer has a vision of the future of American industry, his profession is that of building and constructing, and he knows that a crop of trees cannot be grown in less than thirty years. If our civilization is to develop, we must have timber and water, and trees must be planted now that our children may live. Trees must be saved, and in forest districts local engineering societies can be of great assistance in developing campaigns for the prevention of forest fires. Activity should not be limited, however, to forest districts. Every local engineering group may, with great benefit to the community and to posterity, discuss the problem as related to the state and nation and stir the public to a realization of the need for a policy that will perpetuate our lumber supply.

Charles H. MacDowell.[1]

The Potential Flying Man Power of America

THE following figures may throw some light on one of the problems facing the further development of the aeronautical industry. They refer chiefly to the human material available for service as pilots of commercial passenger-carrying machines of the present types.

The combined experience of the Air Services of the United States and the Allies goes to show that twenty-five years is about the upper limit of age for fliers, although in a number of instances much older men have done excellent service.

As regards the lower age limit, it may be said that while in war service, boys of eighteen have shown splendid courage, it is nevertheless believed that for commercial service none younger than twenty-one ought to be employed. The same war experience has developed the fact that roughly only one out of every one hundred young men possesses sufficient mental development and satisfactory physique to stand the strain of flying. The registration in the first draft showed that there were ten and a half million men in the United States between the ages of twenty-one and thirty-one, or, roughly, one million for each year of age, which would mean four million between the ages of twenty-one and twenty-five. Adding another million to allow for possibilities in the way of exceptionally well-preserved older men, we have five million as our source of flying-man-power material. However, from this number about one million would have to be eliminated to cover unavailable colored population and aliens only temporarily located in the country, leaving a remainder of four million, which, with the ratio of one in a hundred referred to above, gives 40,000 as the apparent maximum number of young men available for service as pilots of commercial passenger-carrying machines.

The experience of the Air Service has shown, however, that college men and men coming from the upper-middle classes of society, due to their better training and better home living conditions, form the majority of those acceptable as pilots. Of course only comparatively few such men would take up the driving of commercial aeroplanes as a regular occupation, and it would therefore be reasonable to assume that at best not more than one-half of the men available for this service would actually go into it, which reduces the number to 20,000. At an average load of six persons per machine, we therefore have a potential transportation capacity of

---

[1] Chairman Reforestation Committee of the F.A.E.S. and President of the Western Society of Engineers.

120,000 passengers, which would be materially cut down by the fact that a pilot cannot fly every day.

In fact, with but 20,000 men engaged in the service it would be difficult to keep more than 10,000 machines in the air at any one time, and this, with the average load mentioned, would mean only 60,000 passengers. If we take into consideration the fact that it was only when the automobiles in the country began to be numbered by millions that they became a factor in transportation, we are led to believe that the time when aerial transportation will attain the dignity of an essential industry is still quite distant, unless, of course, the present aeroplane shall be so rebuilt that it will either carry a far larger number of passengers than it does today, or like the automobile, can be driven by any man of ordinary intelligence and average physical qualifications

The Engineer in Government

[An extract from an interview with Edwin Ludlow, Past-President of the American Institute of Mining and Metallurgical Engineers, which appeared in various forms in the *New York World*, the *New York Tribune* and the *Boston Globe*.—Ed.]

"We have an engineer's civilization and a lawyer's government. Although George Washington, our first president, was an engineer, there have been very few engineers in the Government since, and until Mr. Hoover's selection none has held a cabinet position. This is not by way of complaint. It is a simple statement of fact which, if properly understood, may do much to clear up some of the difficulties which confront America today.

"Engineers do not want a government of engineers. They want a government in which engineers can function on jobs that require engineering, while other services will be performed by those who have the peculiar training which is required for them.

"Engineers do not aspire to the bench, although they could do much to prevent crime and make life move along so smoothly that the courts would not be overworked, as they are at present. I am not one of those who think that government can dispense with lawyers. We need to keep track of precedents. We cannot scrap a whole society as we would rebuild a boilerhouse, for the reason that it takes a generation or two to do the job and a whole people must live in that society while it is being scrapped.

"But government must adopt engineering standards if it is not to become so divorced from the people as to be eventually intolerable. It must adopt them because life has adopted them, because the voter no longer lives merely in his voting precinct, but in his industrial connections, which extend in infinite ramifications throughout the country.

"We don't want a government by any one group, but we do want a government in which the knowledge acquired by every group shall be utilized for the public interest."

"A Healthy State of Change"

REFERRING to the hydraulic turbine in a paper published in this issue of Mechanical Engineering, Mr. H. Birchard Taylor and Lewis F. Moody say that after having reached what was considered for a number of years nearly standardized design, this prime mover "is again in a healthy state of change."

It is not always realized how vigorous and general is this state of flux throughout the world of engineering. In the words of a divine of the 16th century, "Nothing is sacred, not even things sanctified by the usage of centuries."

Nothing that has been in use for centuries or decades is sacred to the modern engineer, who is at all times looking for better ways, with the cheerful expectation that they, in turn, will be discarded for something still better as time goes on.

The Survey of Engineering Progress published in the present issue gives numerous examples of this situation. A British company has developed a new high-resistance alloy of high melting point and ability to withstand the action of acids. The Ford Motor Company is busy completing a process for making iron castings direct from the ore, and in this connection uses a mixer with vacuum walls.

In the glassware industry a device for pressing glassware has been developed which is sensitive enough to act in accordance with the degree that the mold is filled with molten material, thus doing mechanically what the brain of the worker had to do formerly.

In the field of prime movers a Diesel engine has been built in which the cylinder heads acting also as pistons are stationary while the cylinders reciprocate, an arrangement which would have been considered as the height of foolishness ten years ago, but which today operates at a mechanical efficiency of sixty-five per cent.

New materials for making cutting tools are appearing all the time, of which iron is no longer the essential constituent; for example, stellite is made up of cobalt and chromium, and copperite of nickel and zirconium. This young family of non-ferrous cutting alloys has now been joined by the Diamond alloy, composed mainly of chromium, molybdenum and tungsten.

In the power-plant field, Ljungström, the designer of the turbine of the same name, presents an air preheater, the remarkable part of which is that it is so built that there is no transference of heat through metal.

Even the staid and conservative locomotive and marine-propulsion industries have not escaped the universal tendency toward "a healthy state of change." Only five years ago the steam locomotive held undivided sway on the rails. Today a large British railroad is employing gasoline locomotives for switching purposes, while a Canadian railroad is going a step further by equipping its switching locomotives not only with a gasoline engine but with a hydraulic drive. In the marine field where paddle wheels and the Ericsson screw propeller have thus far been the beginning and the end, vane wheels and contrary-turning coaxial screw propellers are being tried out with apparently great promise.

There is undoubtedly a state of change, and the welcome thing about it is that it is generally recognized as a healthy one.

The First World Power Conference

The British Electrical and Allied Manufacturers' Association in coöperation with technical institutions and other trade associations in Great Britain has arranged to hold the First World Power Conference in connection with the British Empire Exhibition in the summer of 1924. The purpose of this conference will be to consider how the industrial and scientific sources of power may be adjusted nationally and internationally. The purpose is to be accomplished by considering the potential resources of each country in hydroelectric power, oil and minerals, by conferences of engineers and authorities on industrial research, by consultations of the consumers of power and the manufacturers of the instruments of production, by discussions on the financial and economic aspects of industry, nationally and internationally, and by conferences on the possibility of establishing a Permanent World Bureau for the collection of data, the preparation of inventories of the world's resources, and the exchange of industrial and scientific information through representatives who will be appointed in the various countries.

The officers and advisory committees are made up of outstanding engineers and industrialists in the British Empire and plans are under way for developing, to a similar extent, coöperation in other countries.

Engineers Elected to Assist Eyesight Conservation Council

Two engineers have been elected to the Board of Councilors of the Eyesight Conservation Council of America. They are Prof. Joseph W. Roe, head of the Department of Industrial Engineering in New York University, and Dr. F. C. Caldwell, professor of electrical engineering in Ohio State University.

Professor Roe is a member of the Executive Board of the American Engineering Council of The Federated American Engineering Societies, and president of the Society of Industrial Engineers. Professor Caldwell is chairman of the Committee on Education of the Illuminating Engineering Society. L. W. Wallace, executive secretary of The Federated American Engineering Societies, is president of the Eyesight Conservation Council which is planning surveys in industrial centers and in city and rural schools to determine the economic and physical damage being caused through failure of parents, teachers and factory managers to correct faults which can be remedied.

Engineering and Industrial Standardization

Approval of Existing Standards by the American Engineering Standards Committee

FOR some time the unification and approval of existing standards will necessarily form an important part of this Committee's work. Its Rules of Procedure (Section R-4) provide that "any standard adopted or in process prior to January 1, 1920, may be approved by the Main Committee, if, in its opinion, the standard has been developed by an organization and procedure substantially in conformity with these Rules, or it has, by actual practice, proven its right to become a standard," without the standard having gone through the machinery of a Sectional Committee. While the most satisfactory way of determining the status which a standard has in industry is to submit it to a regularly organized sectional Committee, there are cases in which such a full procedure would be considered a hardship. Hence this provision.

Before acting upon the approval of a standard submitted under Rule R-4, a notice of its submission to the A.E.S.C. is sent to the technical press, and to the industrial association and technical bodies interested, requesting information as to how the standard is meeting the needs of industry. The standard is then referred to a special committee for investigation.

Special Committees

In order to carry out the spirit of the Sectional Committee method, these special committees contain representatives (accredited for the purpose or regular members of the A.E.S.C.) of those bodies most concerned with the standard under consideration, including the organization submitting the standard. Each special committee must contain, however, at least three members of the A.E.S.C. Usually only organizations most directly interested have representation. This permits these special committees to be small, and hence better fitted for prompt action than they would be if made as large and broadly representative as is the case of regularly organized Sectional Committees.

If the special committee finds that "the standard has been developed by an organization and procedure substantially in conformity" with the Sectional Committee method, approval by the A.E.S.C. is immediately recommended.

In the case of the great majority of existing standards, however, this is not true, and hence the special committee must determine the status which the standard has reached in the industry concerned, and the attitude taken toward it by the principal organizations concerned. Generally, each member of the special committee is able, either formally or informally, to reflect the attitude of the organization he represents. This information is supplemented by that secured from the correspondence resulting from the formal publicity statements mentioned above, and by data and information made available to the Committee from other sources. Of course, these special committees function in a way similar to that laid down for the Main Committee (A.E.S.C.), omitting all consideration of technical detail and confining their attention to personnel, procedure, and status. The special committee does therefore consider and report on the recommendation for the status of the standard as: American Standard, Tentative American Standard, or Recommended American Practice.

Interpretation and Revision

As part of their work of preparing recommendations to the A.E.S.C. on existing standards submitted for approval, special committees recommend the formal designation of one or more organizations as sponsors to provide for the interpretation and future revision of the standard. While the organization submitting a standard is usually found to be the most suitable one to assume the responsibility of a continuing sponsorship, this is not always the case, so careful consideration is always given to this part of the reports.

On June 15 the A.E.S.C. voted to withdraw thec lause in the Rules of Procedure (Section R-4) under which existing standards may be approved without going through the machinery of a Sectional Committee, such withdrawal to become effective January 1, 1924. Hence all standards submitted after that date will be considered by regularly organized Sectional Committees.

VENTILATING CODE SUBMITTED FOR APPROVAL BY A.E.S.C. UNDER RULE R-4

The code for the ventilation of public and semi-public buildings adopted by the American Society of Heating and Ventilating Engineers in 1915 has now been submitted to the American Engineering Standards Committee for approval as American Standard.

This code was prepared by a committee of the American Society of Heating and Ventilating Engineers in response to requests from state commissions, legislative bodies, public-health agencies and other organizations for suggestions to be used in the preparation of legislation and regulation regarding the heating and ventilation of buildings. An endeavor was made to formulate this code in such a manner as to make it cover the general features most essential to the maintenance of public health. It aims to protect the public with the least possible expenditure for equipment and without unnecessarily limiting the methods of obtaining the desired results. Section 1 of the code relates to general matters pertaining to all classes of buildings; the remaining three sections cover the ventilation of schools and colleges, factories, and theaters.

Among the states that have utilized parts of the ventilating code in their regulations are: Illinois, Indiana, Kansas, Massachusetts, Minnesota, New Jersey, New York, Ohio, Pennsylvania, Utah, Virginia and Wisconsin.

A thoroughly representative special committee, including all the important organizations interested in the subject, has been appointed by the American Engineering Standards Committee to investigate the status of this code and the desirability of approving it. Mr. Sidney J. Williams, Chief Engineer of the National Safety Council, is chairman of this special committee. The American Engineering Standards Committee would, therefore, be very glad to learn from those interested the extent to which they make use of this code, and to receive any other information regarding the way the code is meeting the needs of industry.

A. I. E. E. Holds Pacific Coast Convention

The eleventh annual Pacific Coast Convention of the American Institute of Electrical Engineers was held at Vancouver, B. C., August 8 to 11, 1922. Technical papers presented at the opening session were: Power Development on the Colorado River and Its Relation to Irrigation and Flood Control, by O. C. Merrill, secretary of the Federal Power Commission, and 220-Kv. Transmission of the Southern California Edison Company and Some 220-Kv. Researches, by R. J. C. Wood, engineer for the Southern California Edison Company.

Three papers on the subject on high-tension insulators were presented at the morning session on August 9 and four papers on technical education at the afternoon session. The official convention dinner was held Wednesday evening.

H. B. Dwight, electrical engineer for the Canadian Westinghouse Company, Ltd., of Hamilton, Ont., and C. H. Holladay, engineer for the Southern California Edison Company, Los Angeles, Cal., spoke Thursday morning on the subject of transmission systems. A paper entitled Exciter Instability, by R. E. Doherty, designing engineer for the General Electric Company, Schenectady, N. Y., was also presented at this session. The electric propulsion of battleships was discussed by Commander A. M. Charlton, *U. S. S. Tennessee*, at the afternoon session, and in the evening a pictorial symposium of power plant comparisons was delivered by R. J. C. Wood, of the Southern California Edison Co., and Joseph Mini, Jr., of the Pacific Gas & Electric Co.

Among the papers presented at the final technical session on Friday morning were: Electrical Engineering Features of the Electrical Precipitation Process, by G. H. Horne, engineer for the Western Precipitation Company, and Electrical Precipitation of Solids from Smelter Gases, by R. B. Rathbun, of the Research Department of the American Smelting & Refining Co.

F.A.E.S. Report States Facts on Twelve-Hour Shift

Committee on Work Periods in Continuous Industries Presents Report, Entitled Twelve-Hour Shift in American Industry, Embodying Investigations by Horace B. Drury and Bradley Stoughton

AT THE meeting of the Executive Board of the American Engineering Council in Boston on September 8 and 9, the Report of the Twelve-Hour Shift in American Industry was received and ordered to be published. The complete Report will be on sale probably by the middle of October. Its particular appeal to engineers lies in its being a simple statement of facts.

This Report is the result of definite investigations and surveys inaugurated by the Committee on Work Periods in Continuous Industries of The Federated American Engineering Societies. The personnel of this Committee is: Dr. H. E. Howe, Chairman, J. Parke Channing, Fred J. Miller, L. P. Alford, L. W. Wallace, Dwight T. Farnham, R. B. Wolf, and Morris L. Cooke. The Report is in three sections. Part 1, prepared by the committee, is a summary of the field reports contained in Part II and Part III and appears in full below, together with excerpts from Part II. Part II is a report by Horace B. Drury on Two-Shift and Three-Shift Operation in the Continuous Industries. Part III, by Bradley Stoughton, is a Comparison of Two-Shift and Three-Shift Operation in the Iron and Steel Industry.

Mr. Drury's investigations of the twelve-hour shift problem in the steel industry and the progress made in this industry in changing from the two-shift day are well known. He is the author of Scientific Management: A History and Criticism, and of Marine and Dock Labor: Work, Wages, and Industrial Relations during the Period of the War. He was senior examiner in industrial relations for the U. S. Shipping Board and for a number of years was in the Department of Economics and Sociology at Ohio State University.

Bradley Stoughton, formerly secretary of the American Institute of Mining and Metallurgical Engineers, has been connected with various steel companies and was at one time Prof. H. M. Howe's assistant at Columbia University. He has been vice-chairman of the engineering division of the National Research Council, and is the author of the Metallurgy of Iron and Steel, a standard work on the subject. He is the inventor of a convertor for making steel castings and a process for oil melting in cupolas. Since his resignation as secretary of the American Institute of Mining and Metallurgical Engineers he has devoted his time to private consulting work.

I—The Twelve-Hour Shift in Industry

Introduction

IN 1920 members of the engineering profession began an organized study of the twelve-hour shift or "long day" in the operation of continuous process industry. The spirit of the investigation reflected the firm faith of the engineers in facts, and the method adopted was that of fact finding and fact using. Such a study is within the purview of engineering activities, for engineering includes "the art of organizing and directing human activities" in connection with "the forces and materials of nature."

The first engineering meeting devoted to this subject was held in October of the year mentioned at the Engineers' Club of Philadelphia. The topic considered was the technique of changing from the two-shift to the three-shift system in continuous-process industries.[1] The papers and discussions at this meeting gave experiences in changing the basis of operation in the manufacture of paper, heavy and light chemicals, oil and cement, and in mining, in supplying water and in several other industries. There was a common technique throughout all these experiences. The record of this meeting, however, did not show to what extent these successful though isolated cases had influenced the respective industries to which they belonged.

Shortly after this meeting an investigation was conducted to determine the progress made in the steel industry in changing from the two-shift day. This study was made possible by a grant from the Cabot Fund. The work was done by Horace B. Drury who reported at a joint meeting of engineering societies held in New York in December, 1920.[1] In this report were listed upward of 20 small steel plants which had changed from the two-shift to the three-shift system with more or less success. It was recognized and stated that the problem of working a like change in the plants of the U. S. Steel Corporation and the large independents, such as Jones & Laughlin and the Bethlehem Steel Company, was quite different from that encountered in the smaller plants.

Early in 1921 the Taylor Society requested the International Labor Office at Geneva to inquire into the status of two-shift work in countries other than the United States. A report was recently issued from the Washington office in memorandum form.[2] It is to the effect that the shorter day is now completely established in the 15 foreign countries answering the questionnaire. Early in 1921 Mr. Drury completed an inquiry into the twelve-hour shift problem of the larger steel manufacturers in the United States. This report was issued in 1922 by the Cabot Fund Trustees. Also in 1921 the Cabot Fund made a grant to The Federated American Engineering Societies to carry on the two studies forming this report. The committee on Work Periods in Continuous Industry was appointed to direct the investigation. To Mr. Drury the committee assigned the task of ascertaining:

1 The extent of two-shift work in continuous-process industries other than the manufacture of iron and steel;

2 The experience of those manufacturers who had changed from two-shift operation to the three-shift or some other system.

To Bradley Stoughton the committee assigned the task of studying and reporting upon the technical aspects of changing from a two-shift to a three-shift system in the iron and steel industry.

There is no direct relationship between the question of abandoning the twelve-hour shift system and the question of adopting the eight-hour shift system. In a sense it is accidental that most employers in changing from the long day have been forced by the mathematics of the situation to adopt a system of three shifts of eight hours each. Certainly the change itself has involved no judgment as to the relative merits of a working day of eight hours as compared with a working day of any other length shorter than 12 hours.

Relatively only a small part of industrial work, 5 per cent to 10 per cent, is on processes which require continuous operation and the number of workers is relatively few. The desirability of abandoning the two-shift system lies not in its extent but in the fact that the 12-hour shift day is too long when measured by twentieth-century ideas as to the proper conduct of industry. Decisions are influenced today by humanitarian considerations as well as the economic, which demands that length of a day which will in the long run give maximum production.

This declaration the Committee believes is not controversial.

Further, there is practical unanimity of opinion in industry as to the desirability of the change provided the economic loss is not too great. The weight of evidence indicates that the change can usually be made at a small financial sacrifice on the part of the workers and of the management. Under proper conditions no economic loss need be suffered. In certain instances, indeed, both workers and stockholders have profited by the change.

Facts developed by our investigation definitely prove that there is no broadly applicable way of striking a balance between the losses and gains inherent in the change from the two-shift system of operation. If any one fact stands out above the others it is that the change cannot advantageously be made by fiat. Our judgment is that to effect the change suddenly or without adequate preparation is sure to result in lowered production. It is also our opinion that when the change is preplanned and the coöperation of every one is enlisted gains will accrue to every one concerned—to workers, management, owners and the public.

---

II—Continuous-Process Industries

The Drury report is a general survey of all industries operating continuously twenty-four hours a day, with special consideration to industries other than iron and steel.

There are few continuous industries which do not have twelve-hour plants. Of some forty or fifty continuous industries a number are overwhelmingly on three shifts. The majority are partly on two shifts and partly on three shifts with three-shift operation in the preponderance. There are a half-dozen industries in which two-shift operation is so nearly universal that it is difficult to find an exception. Outside the steel industry the total number of employees on eight-hour shifts is now considerably larger than the total number of employees on twelve-hour shifts. Taking into consideration all continuous industries, between one-half and two-thirds of all workers on continuous operation are on shifts averaging twelve hours.

The leading continuous industries are:

Group I:
- Iron and steel
- Non-ferrous metals
- Glass
- Portland cement
- Lime
- Brick
- Pottery

Group II:
- Heavy chemicals
- Fertilizers
- Explosives
- Dyes
- Industrial alcohol
- Wood distillation
- Refined corn products
- Soap
- Glue
- Drugs, etc.
- Electrochemical industries
- Sugar
- Table salt
- Petroleum
- Cottonseed oil
- Other oils

Group III:
- Paper
- Flour
- Rubber
- Breakfast foods
- Automobiles
- Textiles
- Mines

Group IV:
- Power
- Gas
- Water supply
- Ice
- Shipping
- Railroads
- Street railways
- Telegraph and telephone
- Mails and express
- Policemen, firemen
- Watchmen

Non-Ferrous Metals. The three-shift system prevails in the non-ferrous metal industries. The change took place during the War, spreading from the West to the East and South.

Glass and Cement. Until recently (1922) the twelve-hour shift was the rule for glass-furnace workers. Other employees about a glass plant are on eight-hour day work. At one window-glass plant, out of 1,300 employees 175 were on a twelve-hour basis. About six years ago the Pittsburgh Plate Glass Co. went to three shifts. Three years ago the majority of other producers went on three shifts.

The cement industry is the second most important industry predominantly on two shifts. In 1920 the largest and third largest companies changed to three shifts.

Lime. About 15 per cent of the men in the plants investigated were on shift work. In most parts of the country the lime industry is uniformly on two shifts.

Brick and Tile, Etc. There are more than 100,000 men in the United States employed in this industry, of whom about 11,000 are on shift work—for the most part on two shifts. In some Philadelphia plants men are on duty 36 hours at a stretch. In Illinois many plants have changed to the three-shift system.

Chemical Industries. Most of the producers of heavy chemicals are on three shifts. Acid-plant employees in fertilizer works are almost universally on twelve-hour shifts. Most continuous-process workers employed in explosive, industrial alcohol and soap plants are generally on this shift. Drug plants are on three shifts. The Niagara Falls electrochemical industries are on three shifts.

Sugar, Salt, Petroleum, Cottonseed Oil, Etc. The Louisiana sugar mills are for the most part on twelve-hour shifts. One sugar refinery in Texas tried three shifts and later reverted to two. The American Sugar Refining Co. changed to three shifts in 1918. Nearly all the beet-sugar plants are on twelve-hour shifts, 210 out of the 225 employees at one Michigan plant being so employed.

In the salt plants the twelve-hour day was formerly almost universal. In Michigan half the men are on shift work—mostly on three shifts.

No examples of two-shift work were found in the petroleum industry. The plants of the Standard Oil group are uniformly on three shifts. Cottonseed crushing presents one of the largest twelve-hour shift problems during the months in which the plants are in operation. Nearly all employees are shift workers in this industry.

Paper, Flour, Rubber, Etc. There are about 88,000 persons in the paper industry, most of whom are on continuous-operation work, although the tendency is toward less shift work. Most of the plants operate on three shifts. Thirty per cent of the workers in Massachusetts were in 1912 on twelve-hour shifts and 70 per cent on eight-hour shifts. In 1921 one of the large associations of paper manufacturers reported 20 per cent of the workers still on two shifts.

Practically all the large flour mills are on three shifts. Most rubber plants have operated under the three-shift system since their establishment.

Automobile plants are for the most part on eight-hour shifts, of which they usually operate two or three shifts per twenty-four hours.

The preparation of cereal foods is usually on three shifts. Some plants use the three-shift operation for women and the two-shift for men. In the textile industry the three-shift plan is used to some extent in the North, but in the plants in the South two shifts are employed, the length of the shifts varying greatly. The hours of work in mines, because of the influence of trade unions, and the nature of the work are fixed at about eight hours per day, with some exceptions in auxiliary occupations, as for engineers, firemen and pumpmen.

Power, Gas, Water Supply, Etc. Work periods in power plants are usually arranged for overlapping shifts of different lengths to provide for variations in the degree of activity. The power departments of factories have been run on the twelve-hour shift down to the last few years. At present there is a tendency to put engineers and firemen on three shifts. The proportion of shift workers in gas works is large. There has been a retention of the system of nine or ten-hour overlapping shifts. In Philadelphia and outlying districts the ten-hour shift is used in conjunction with the eight-hour shift. Water-works plants require less labor for continuous operation than any other public utility. Most plants are now on eight-hour shifts.

Conclusions

1 As to the extent of continuous work in American industry, there are upward of forty continuous industries operating more or less completely upon a shift system. They employ between 500,000 and 1,000,000 wage earners on shift work. Their families constitute from 1,500,000 to 2,000,000 persons, who are dependent upon earnings from shift work.

There are 300,000 wage earners working on twelve-hour shifts. They and their families number more than one million persons.

2 The logical alternative to the two twelve-hour shift system is the three eight-hour shift system, and this is the usual procedure. Nevertheless, other shift systems have been resorted to in a limited way, in changing from the twelve-hour shift. Among these are:

a Operation for a period shorter than twenty-four hours in each calendar day, permitting of a cessation of work from two to four hours, thus establishing two shifts of ten or eleven hours each

b Arranging the work on a nominal twelve-hour shift, so that it can be completed in ten or eleven hours

c Arranging overlapping shifts, thus securing three nine-hour or three ten-hour shifts in twenty-four hours

d Arranging nine- and ten-hour shifts on the five-shift plan.

3 No technical difficulties have been encountered by an overwhelming majority of the plants which have changed from two- to three-shift operation.

There is usually no relationship between the duration of the proc-

ess and the length of the shift, whether the latter is twelve hours long, or a shorter period.

The seeming disadvantage of having three men instead of two responsible for a given product, process, or equipment is overcome by standardizing procedure and establishing control through precision instruments.

4 It is not possible to give inclusive data as to the effect upon the number of shift workers of the change from two- to three-shift operation, because of variations in conditions. In many small plants the number of shift workers has increased in proportion to the increase in number of shifts. In many large plants the number of shift-workers has remained substantially constant when changing from two- to three-shift operation

5 The following factors should be considered in changing from two- to three-shift operation

- *a* The readiness, or unreadiness of the men to do more work per hour under the shorter shift
- *b* The responsibility of management as expressed in planning, supervision and control, which must be of a higher quality than usually prevails under two-shift operation
- *c* The fluctuations in individual earnings and labor costs
- *d* General industrial and economic conditions to determine the time for making the change
- *e* The relationship of work periods for shift and for day workers
- *f* The relationship of wage rates for shift and for day workers
- *g* Number of working days in a week
- *h* Rotation of shifts.

6 The effect of the eight-hour as compared with the twelve-hour shift operation on the quantity and quality of production, absenteeism and industrial accidents has been satisfactory where good management and coöperation of labor have been secured. In practically every major continuous industry there are plants which have increased the quantity of production per man as much as 25 per cent. In a few exceptional cases the increase has been much higher. Evidence shows also an improvement in quality of production following the reduction in the length of shifts.

7 A comparison of wage rates under the eight-hour-shift operation with the rates under the ten-hour shift indicates a general tendency to increase the rate per hour under the eight-hour shift, so that the daily earnings will be the same as they were before the change. In some instances a compromise was made whereby the rate per hour was increased sufficiently to make the daily earnings equivalent to a ten-hour day. In other cases a 25 per cent increase in the rate per hour met with the approval of the men.

8 There is a natural divergence of opinion as to the advantages and disadvantages of the three-shift operation, but the weight of the evidence and the most positive statements are in favor of the three-shift operation.

9 The evidence is conclusive that the extra leisure time of the men under the shorter working day is used to good advantage. It is spent in gardening, truck farming and in doing odd jobs which otherwise would have to be paid for or would not be done at all.

10 A few plants have reverted to the two-shift operation after a trial of the three-shift system. This proportion to the number continuing operation on three shifts is so small as to be negligible. The weight of evidence shows that when a plant changes to three-shift operation it is very unlikely to revert to the former system.

III—The Iron and Steel Industry

The report of Mr. Stoughton deals with the change from the twelve-hour shift to the eight-hour shift in the iron and steel industry from the technical viewpoint. It deals with the practicability of making the change, its effect and the most economical method of changing.

In 1919 the United States Steel Corporation employed approximately 70,000 twelve-hour employees. Altogether, there are perhaps 150,000 wage earners in the entire steel industry on twelve-hour shifts.

A wise executive policy takes into full consideration the importance of the intellectual, the psychological and the physical well-being of labor, realizing that an immediate saving secured by over pressure inevitably becomes a loss in the long run. A refusal to coöperate on the part of the workers is an economic loss. Furthermore it is obviously of no permanent benefit to the men if their hours are shortened beyond the point where the industry can survive under competitive conditions.

The factors to consider in determining the economic number of working hours for a worker are:

- *a* His productivity
- *b* His skill, carefulness, endurance, alertness, intelligence, judgment, regularity, morale and goodwill
- *c* His attraction to the work—so that the industry may benefit from the maximum supply of labor of the highest type
- *d* His persistence in the work so that once he is trained and his qualities known to the management he will remain as an asset to the industry.

Situation in the Iron and Steel Industry. The twelve-hour day is strongly established in the iron and steel industry by long custom and by its unusual adaptability to production requirements.

Recent progress, however, has been in the direction of a shorter day as well as in the reduction of the proportion of men on duty seven days a week. This is shown by the following tabulation which gives the percentage of men so employed.

	Seven days per week		Working 12 hours	
	1910	1920	1910	1920
Blast furnaces	75%	29%	69%	63%
Bessemer mills	18%	12%	65%	75%
Open hearth	24%	17%	76%	50%

Recent improvements in equipment and the adoption of electrical appliances have greatly decreased the frequency and the duration of interruptions of the different processes due to breakdowns, especially in the rolling mills. Also mechanical and other labor-saving devices have lessened the severity of peak loads due to the processes themselves, both in respect to physical endurance and heat exposure. For instance:

1 Oxygen is used to open the tap hole, and mud gun to close it.

2 The cast house with its severe manual labor has been replaced by an arrangement which allows the liquid pig iron to run directly into ladles supported on railroad cars. Under this arrangement a former crew of twenty-one men is reduced to five—sometimes to three men.

3 Ore and the materials formerly piled, shoveled, and wheeled by hand are now handled from railroad cars to the furnace hopper entirely without manual labor. Six handle 2,000 tons when previously it required twenty-three to handle 800 tons. This enables the fillers to work continuously.

4 At the Ford plant (which is a blast-furnace only), instead of allowing the fillers to rest occasionally as is usual in the twelve-hour plants, with consequent lowering of the stock-line level in the furnace and of the furnace efficiency, an automatic record is kept of the level of the stock line in the furnace, of the temperature of the top gases and of the time at which the charging skip makes its trips. Continuous adherence to the standards set can be insisted upon and the rest periods and furnace inefficiency eliminated because of the high wages and the eight-hour day. This condition affects the men in front of the furnace as well as the fillers.

These changes in blast-furnace operation have made possible:

- *a* Reduction in number of workmen
- *b* Increase in overall efficiency
- *c* Elimination of floating gang
- *d* Reduced absence, tardiness, labor turnover
- *e* Greater regularity of operation and loss of time
- *f* Fewer accidents and breakdowns
- *g* Less costly repairs
- *h* Decreased cost of production.

It is emphatically asserted by blast-furnace managers working the eight hours that the higher grade of labor attracted by the shorter hours, the greater care and alertness, better work, and more skillful operation are all reflected in a saving in cost of production as enumerated in the last five items above. Cost figures are confidential but furnace operators working under the eight-hour day assured the investigator on more than one occasion that the cost of producing pig iron is less on the eight-hour than on the twelve-hour day.

At the Ford plant, although the men are paid 75 cents and upward per hour and work only eight hours—as compared with 27 to 30 cents per hour at various twelve-hour plants visited; nevertheless

they make pig iron cheaper than it can be bought. This is attributed to the greater efficiency of labor and of operation.

In the case of open-hearth furnaces:

1 The charging machine has greatly reduced the work of the crew on the charging platform
2 Electric appliances for raising furnace doors, mechanical appliances for changing valves, etc., have reduced labor
3 Oxygen is used in tapping and compressed air for repairing the hole. A mechanical appliance has replaced hand shoveling of recarbonizer into the ladle. Repairs are made with the mud gun.

Economical open-hearth operation is dependent upon the care, expertness, and loyalty of the men. The shirking of duty is costly. Carelessness is more likely to occur on a twelve- than on an eight-hour shift.

In the case of rolling mills, eight-hour-shift operation produces a decided increase of efficiency in the case of the lever men, manifested in:

a Increased output
b Less "cobbles" or spoilage
c Less repairs
d Elimination of "spell hands."

Method of Procedure. To successfully change from the twelve- to the eight-hour shift certain definite preparations must be made:

1 The equipment must be in satisfactory condition to respond to increased intensity of operation
2 The coöperation of the workmen must be secured
3 Necessary labor must be available
4 The technical staff must be prepared to furnish full information regarding available labor-saving appliances
5 Existing "bottle necks" must be eliminated and probable ones avoided
6 Peak loads must be studied with special reference to the installation of mechanical appliances
7 The change must not be made during a period of labor unrest
    a After strife
    b When bitterness exists
    c When mutual confidence is lacking
    d When labor is arrogant or elated by the defeat of the management
8 The change must not be made too suddenly
9 Management must be able to influence thoroughly against
    a Tardiness and absence
    b Deliberate shirking
    c Misuse of extra hours of free time.

10 Where possible, make time studies of the work to determine how much more the twelve-hour crew could produce per hour if it worked with greater efficiency. Pay the same hourly rate for eight hours as for twelve and add a bonus which will enable the men by becoming more efficient to maintain their daily income.

The Economic Situation. The United States has the most profitable iron and steel industry in the world, making more money and more output than all the rest of the world put together and exporting its product in successful competition with foreign countries. The majority of managers and executives with whom the matter was discussed believe that the good of the industry can be better served by eliminating the twelve-hour day than by increasing dividends, provided by means of labor-saving devices and in other ways this step can be taken without serious injury to the industry.

The fact that already many plants operate successfully on the three-shift system indicates that profits need not suffer if the change is made with wisdom. The cost of all labor on either system at the blast furnace is less than $1 per ton of pig. Judge Gary testified before the Lockwood Committee in June, 1922, that the U. S. Steel Corporation could produce at $2 per ton less than its competitors. This shows what low overhead and technical skill can accomplish.

The operating labor in the case of pig iron is from 5.8 to 8 per cent of the total manufacturing cost. Only a part of the labor in the industry is working the twelve-hour day. If that labor was changed to the eight-hour day and paid as much per day as it is now getting for twelve-hour work even without securing any compensating advantages through increased efficiency, morale, etc., the total manufacturing cost of the product would be increased only from 3 to 15 per cent. This is in most cases less than the variations in cost already experienced by competing plants, due to difference in efficiency of equipment, technical skill, purchasing, location, capital resources, overhead expense and advantages due to good management.

As a matter of actual experience, it is known that some plants have changed from the twelve-hour to the eight-hour day and reduced their labor costs. Others have reduced their total manufacturing costs. Others are operating on the eight-hour day with satisfaction to management and stockholders.

Results in such plants may be summarized as follows:

a Although the plants which have adopted the three-shift system are paying wages a little less than is paid in corresponding plants working twelve-hour shifts, the three-shift plants have sufficient labor, both skilled and unskilled.

b The management believes that the shorter hours attract a better class of labor.

c Every executive interviewed stated that the labor turnover is less on the three-shift system than on the two-shift system.

d Sufficient skilled labor can be trained in the plant if the change is made with the coöperation of the men, and if it is made gradually.

e It is unnecessary to pay a full twelve-hour wage to skilled labor to secure a sufficient number to work the eight-hour day.

Advantages of the Eight-hour Day. The change from the twelve to the eight-hour day has secured results sufficient to compensate in whole or in part for the extra cost:

1 Increased efficiency manifested in increased production per man per hour and per machine per day due to:
    a Better physical and mental condition of the men
    b Better class of men attracted
    c Better conduct of operation
    d More uniform operation
    e Better quality of product
    f Less fuel used
    g Less waste
    h Less repairs to equipment
    i Longer life of apparatus.
2 Better morale resulting in:
    a Less absence and tardiness
    b Less shirking
    c Better discipline due to:
        Better spirit of the men
        Greater pressure which foremen can and will exert because they do not have to hold back out of sympathy for tired men.

3 Elimination of the "floating gang" which is maintained to give twelve-hour men a day off a week.

4 Greater prestige with the public—which is invaluable in time of strife.

GENERAL CONCLUSIONS

There are certain outstanding conclusions in regard to the change from the twelve- to the eight-hour day which occur in both reports:

1 The tendency throughout the world is toward the abolition of the twelve-hour shift.

2 In almost every continuous industry there are plants which are operating on an eight-hour-shift basis in competition with twelve-hour-shift plants.

3 To make the change from the three-shift operation successfully and economically it is necessary that:
    a The majority of the workmen appreciate the value of the extra leisure
    b The workmen be willing to concede something in the way of daily income. The plan which divides the extra labor cost equally between the men and the company has been acceptable in a number of cases.
    c A survey of the field be made for labor-saving equipment and methods of management which will facilitate the work after the change is made
    d The plant management study equipment and methods of operation and make every change in the plant and in the organization possible to facilitate operation under the three-shift system

e All equipment be in condition to respond to increased intensity of operation

f The workmen be instructed in their duties under the new system and the coöperation of the whole organization be secured

g The extra trained labor required be available

h The time for the change be selected with great care. Periods of labor unrest must be avoided, the success of each step assured before another is taken.

5 In a number of plants where the change has been made with success the management reports these results:

a Better physical and mental condition of workmen

b Improvement in class of workmen

c Less shirking, tardiness, absenteeism and labor turnover and industrial accidents

d Improved spirit and cooperation of workmen

e More exact adherence to instructions as to working methods

f More uniform methods with consequent attainments of standards, etc.

g Better quality of product

h Increased output per man per hour

i Less material used

j Wastes eliminated

k Longer life of equipment and less repairs

l Greater prestige with the public.

Excerpts from Mr. Drury's Report

Mr. Drury's conclusions are reproduced in the foregoing pages. His report gives the results of his investigations in forty-four centers of forty-two continuous industries. A reproduction of the findings in these industries is out of the question in these pages but three short excerpts from the facts relating to cement, soap and sugar refining are of interest and are reproduced here.

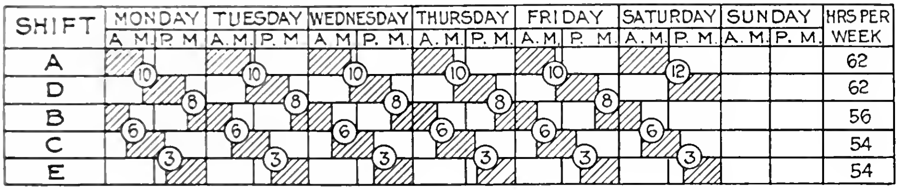

FIG. 1 FIVE-SHIFT SYSTEM, PROCTOR & GAMBLE COMPANY

TABLE I COMPARATIVE LABOR EFFICIENCY, 86 PORTLAND CEMENT PLANTS, 1920 (Data supplied by the Committee on Conservation, Portland Cement Association)

		Man-hours to produce one barrel		
Shift system	Number of plants	Average all plants in group	Most efficient plant in group	Least efficient plant in group
Two-shift group	51	1.035	0.551	1.940
Three-shift group	22	0.823	0.466	1.540
2–3 shift group	13	0.756	0.470	1.140

CEMENT

Table I shows comparative labor efficiency in eighty-six plants in the cement industry. In 1920, the year this table was compiled, these eighty-six plants made up between fifty and sixty per cent of the cement-making capacity in the country. The small quantity of man-hours required per barrel of cement when using a combination of two or three-shift systems is especially noteworthy. This combination provides for the use of two-shifts in departments where conditions of temperature and supervision are not so severe.

SOAP

In the manufacture of soap the general sentiment in the industry is against continuous operation. However, about twenty-five per cent of the employees of the Proctor & Gamble Company are on continuous work. In the spring of 1921 this company installed a modification of the three-shift system called the five-shift system. This scheme gives shift workers daily turns of nine or ten hours. The number of shift workers is constant throughout the twenty-four hours and each man reports for duty the same hour each day of the week. This is shown in Fig. 1. The conspicuous feature of this plant is the introduction of two interweaving series of shift workers.

The five-shift system as thus outlined has two important characteristics other than its even succession of nine and ten-hour shifts:

First, never more than half of the men are relieved at any one time, obtaining thereby a greater continuity in the work.

Second, a man does not continue today the work which he did yesterday, but takes up what his neighbor on the parallel shift had been doing. This makes it necessary to teach men to serve in two positions. It will be observed that no shift begins or ends work between 12 midnight and 6 a.m.

At the end of the first six months of operation under this system, the company expressed satisfaction with the plan. The production per hour was as much as under the three-shift system. The results were decidedly better than under the two twelve-hour shift system. The five-shift arrangement meant some more work to teach workmen two different jobs.

REFINING OF SUGAR

More than usual importance attaches to the question as to whether a sugar refinery can operate on three shifts without increasing cost. The industry in manufacturing and retailing is an example of a tremendous business done on a moderate and indeed close margin of profit. Competition is intense. It would be impossible for one company to assume a manufacturing cost substantially higher than others. So it is worth while to give special attention to the experience of the American Sugar Refining Company which went to three shifts in the spring of 1918.

There are two elements in the question of cost: (1) The extra compensation due to increased hourly rates and number of men; and (2) productive efficiency.

In the case of the American Sugar Refining Company the first of these two elements was so favorable on three-shift operation as to practically solve the problem of cost.

At the time of the change in the spring of 1918 there was no demand for a reduction in hours, but general conditions were such as to make it likely at any time. It was also expected that an increase in wages would be demanded. In view of the general conditions and the long desire to change to three shifts, the men seized an opportunity to put hours and wages on such a basis as to avoid friction. The management therefore reduced the hours from 12 to 8 and increased the hourly wage rate 50 per cent. The men thereby suffered no appreciable loss in weekly earnings. The company on the other hand did not face any extra wage cost due to the change, for wages in competing plants on a twelve-hour basis were soon increased 50 per cent.

Nevertheless, the change to three shifts also worked out favorably as respects the second aspect of the cost question, the productive efficiency. The company has no exact figures covering the subject but it is the judgment of the men in charge both in the general office and in the largest of the refineries that the efficiency of employees is 15 per cent higher than it was on two-shift operation. The management knows, for instance, that on jobs where the work has remained substantially unchanged, the men are doing more now than their predecessors were doing ten years ago. The figure quoted does not have reference to the output of equipment, but that has

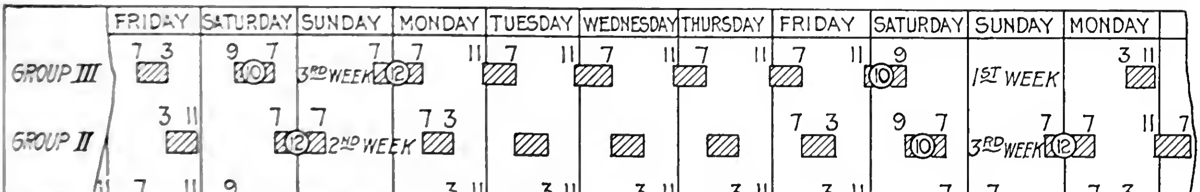

FIG. 2 ONE DAY'S REST IN SEVEN AS WORKED OUT IN THE BROOKLYN PLANT OF THE AMERICAN SUGAR REFINING COMPANY

apparently improved. In 1921 the Brooklyn Refinery broke output records for many years past. The management says that absenteeism and labor turnover have decreased.

According to the schedule, the groups work 54, 50 and 52 hours per week, or 52 hours per week average. Overtime is paid for any work done between 7 a.m. Sunday and 7 a.m. Monday, so as to make the average number of hours pay per week amount to 54. But ordinarily the work stops at 6 a.m. rather than 7 a.m. Sunday morning giving an actual weekly average of $53\frac{2}{3}$ hours pay.

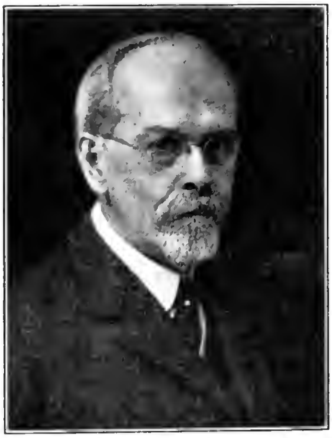
It will be observed that two Sundays out of three the men get 24 hours off, the third Sunday 54 hours. One week end, a given group works one 10-hour shift; the next week end, it works one 12-hour shift; and the third week end it works a 10-hour shift before and a 12-hour shift after the period off. Through the week all shifts are 8 hours. The minimum rest period between shifts is 16 hours.

The plant itself operates all but 12 hours, or in practice 13 hours, out of the week.

Fig. 2 illustrates an interesting feature of the three-shift system as worked out at the Brooklyn Refinery. It is a plan for providing one day's rest in seven (as required by the New York State Law) without the introduction of relief men. The day-workers of the American Sugar Refining Company are on a 50-hour week, with a few on 60 hours. On Sunday about 200 men (in the one refinery) work on repair work which can not be done during the week. These men are given a week-day off.

Coleman Sellers, Jr., Former A.S.M.E. Manager, Dies

Coleman Sellers, Jr., was born in Cincinnati, Ohio, September 5, 1852 and died after an acute illness of several months in Bryn Mawr, Pa., on August 15, 1922. Mr. Sellers' health became impaired as a result of his heavy duties during the war as head of the draft board in his district.



Coleman Sellers, Jr.

After an early education received in the private schools of Philadelphia, Mr. Sellers entered the University of Pennsylvania, where he was a first-honor man throughout his course. He was graduated in 1873 with the degree of Bachelor of Science, and three years later received his Master's degree for shop tests and a thesis relating to steam-boiler injectors. He entered the employ of William Sellers & Co. in November, 1873, and from 1886 to 1902 was assistant manager. In 1902 he was appointed engineer, and on the death of William Sellers was made president of the company. He continued in these capacities until the time of his death.

Mr. Sellers was of the sixth consecutive generation of a family engaged in the mechanical arts. His father, Coleman Sellers, a Past-President of The American Society of Mechanical Engineers, had a long career as an inventor. The sound judgment, ingenuity and experience of Coleman Sellers, Jr., contributed in full measure in maintaining the high reputation of his company as a designer of machine tools and appliances in its special field.

From 1890 to 1893 Mr. Sellers served The American Society of Mechanical Engineers on its Board of Managers; he was among the earliest to join the Society, having become a member in 1882. He was also a member of the American Philosophical Society, the American Society of Naval Architects and Marine Engineers, the American Academy of The Fine Arts, the University Club of Philadelphia, the City Club, Contemporary Club, Pennsylvania Society of Sons of the Revolution, and the New England Society of Pennsylvania. He was one of the founders of the Philadelphia Engineers' Club, had served on the Board of Managers and later as vice-president of The Franklin Institute, was a former president of the Chamber of Commerce of Philadelphia, and from 1908 until his death was one of the three State Commissioners of Navigation for the Delaware River.

Book Notes

Les Applications Elémentaires des Fonctions Hyperboliques a La Science de L'Ingénieur Electricien. By A. E. Kennelly. Gauthier-Villars et Cie, Paris, 1922. Paper, 6×9 in., 153 pp., diagrams.

Dr. Kennelly spent the academic year 1921–22 as an exchange professor in France, where he delivered a course of lectures in universities and engineering schools upon the applications of hyperbolic functions to electrical engineering problems. This monograph, based upon these lectures, places before the French student, in abridged form, the material already published in English by the author.

Chain Stores. By Walter S. Hayward and Percival White. First edition. McGraw-Hill Book Co., New York, 1922. Cloth, 6×8 in., 411 pp., illus., \$3.50.

This book sets forth the principles of the operation, organization, management and control of chain stores, and is intended for the executive at headquarters, the branch manager and his assistants. The authors hope it will also prove stimulating to independent retailers and others interested in methods of distribution.

Crain's Market Data Book and Directory of Class, Trade and Technical Publications. Second edition, 1922. G. D. Crain, Jr., Chicago. Cloth, 6×9 in., 456 pp., \$5.

This is a reference book for advertisers. An account of trade, industry and profession is given which presents the statistical and marketing data necessary to give the advertiser or merchant a picture of the field as a whole. Each account is supplemented by a full list of American trade journals devoted to that industry, with their addresses, circulation, advertising rates, etc. A list of important foreign trade journals is included.

Elektrische Behandlung Von Gasen. Herausgegeben von Henri Silbermann. Dr. Max Janecke, Leipzig, 1922. Paper, 6×8 in., 348 pp., illus., diagrams, \$3.20.

This work is a summary of information upon the effect of electric discharges upon gases, especially the atmosphere, as disclosed by an examination of the German patent records. The subjects discussed are the activation of oxygen (preparation of ozone), the separation of solid or liquid particles from gases (purification by dust and mist removal) and the double decomposition of reaction masses containing at least two elements (synthesis of nitric oxid, ammonia, cyanogen, etc.). The book is a convenient record of the present state of these arts.

Elements of Radio Telephony. By William C. Ballard. First edition. McGraw-Hill Book Co., Inc., New York, 1922. Fabrikoid, 5×7 in., 132 pp., illus., plates, diagrams, \$1.50.

This book gives a simple discussion of what happens when messages are sent and received by radio, of the apparatus required to produce these effects, and of its method of operation. It also gives practical unbiased information for the experimenter who wishes to learn what apparatus is necessary to produce certain results. Being intended for non-technical readers, the use of mathematics is avoided almost entirely.

The Gantt Chart. By Wallace Clark. Ronald Press Co., New York, 1922. Cloth, 6×9 in., \$2.50.

This book explains the principle of this chart, the method of making and reading it, and shows its application to machine, man, planning, load and progress records. One chapter describes their use by the Shipping Board during the war. It will enable those interested to apply this method of charting their records to their own activities.

High-Voltage Power Transformers. By William T. Taylor. Sir Isaac Pitman & Sons, Ltd., London and New York, 1922. (Pitman's technical primer series.) Cloth, 4×6 in., 117 pp., illus., diagrams, \$0.85.

A general practical survey of the characteristics, construction, installation, operation and troubles of modern high-voltage power

transformers. Intended for station operators and general electric engineers and so does not treat problems of fundamental design, details of construction and similar topics which chiefly concern manufacturers.

Hydraulics with Working Tables. By E. S. Bellasis. Third edition. E. P. Dutton & Co., New York, 1922. Cloth, 6×9 in., 348 pp., tables, illus., $8.

In this edition the book has been brought thoroughly up to date and subjected to careful and drastic revision. The chief object is, as before, to deal thoroughly with the facts, laws and principles of hydraulics, and to keep always in view their practical aspects. Fresh discussions on all the most important coefficients are now given and specific recommendations are made. A new set of coefficients for pipes is given.

Fresh matter has been added on weirs and weir-like conditions, on discharge measurement by means of pipe diaphragms, on standing waves and on the laws governing silting and scour. The book is intended to meet all the requirements both of the student and of the engineer.

Hydro-Electric Installations of India. By Shiv Narayan. The Author, Poona, India, 1922. Cloth, 6×10 in., 302 pp., illus., 9 rupees.

This book presents in popular form the principal facts concerning the hydroelectric plants and projects of India. It also explains the hydraulic and electrical principles involved, the general design and installation of plants and the economic factors to be considered. The work is intended to direct attention to the water-power resources of the country and to serve as a guide to engineers and capitalists interested in the utilization of them.

Industrial Physics Mechanics. By L. Raymond Smith. First edition. McGraw-Hill Book Co., Inc., New York, 1922. Cloth, 5×8 in., 226 pp., illus., diagrams, $1.75.

The present trend in education has created a demand for textbooks in which the material presented is closely connected with the every-day life of the student. This volume is an attempt to meet this demand by providing an elementary, practical textbook on mechanics, suitable for use in high schools and vocational schools.

Marine Power Plant. By Lawrence B. Chapman. First edition. McGraw-Hill Book Co., New York, 1922. Cloth, 6×9 in., 320 pp., illus., diagrams, $4.

The purpose of this book is to bring before the student the thermodynamics of the marine power plant, the types of machinery used for ship propulsion, and to give him a comprehensive idea of the layout and purposes of the auxiliary machinery. It is intended as a first book in marine engineering for students of naval architecture, marine engineering and ship operation, but should prove useful also to sea-going engineers and shipowners.

Mechanical Testing. By R. G. Batson and J. H. Hyde. Vol. 1. E. P. Dutton & Co., New York, 1922. (Directly-useful technical series.) Cloth, 6×9 in., 413 pp., plates, illus., diagrams, $9.

The object of this book is to place before the engineer, the manufacturer and the student the conditions governing modern testing, the particulars of standard testing-plant equipment and its limitations and the information necessary to appraise the results obtained at their true values. Volume one is confined to materials of construction, metals, timber, stone, brick, concrete, limes, cements and road materials.

Modern Practice in Heat Engines. By Telford Petrie. Longmans, Green and Co., New York, 1922. Cloth, 6×9 in., 264 pp., illus., plates, diagrams, $5.

A concise treatment of the subject of power from heat engines which attempts to show how far theory may be applied to the design of modern types. The book is divided into three sections, steam, prime movers, and internal-combustion engines. Each section contains chapters descriptive of late types and on the principles of design. The results of a number of reliable modern tests are given.

Modern Pumping and Hydraulic Machinery. By Edward Butler. Second edition, revised. Charles Griffin and Co., Ltd., London, 1922. Cloth, 6×9 in., 475 pp., illus., diagrams, $9.

The author has attempted to present in a clear, concise form information specially useful to engineers, designers and others engaged in the construction or application of pumping and hydraulic machinery to various purposes. The whole range of pumping appliances, as well as the machinery used in hydraulic transmission and power generation, is treated systematically and exhaustively.

Practical Wireless Telegraphy. By Elmer E. Bucher. Revised edition. Wireless Press, New York and London, 1921. Cloth, 6×9 in., 336 pp., illus., diagrams, $2.25.

The author endeavors to give non-technical students and practical telegraphers an understanding of the working of modern commercial apparatus. Stress is laid upon the construction of apparatus and the methods of manipulating it, without attempting a complete account of the scientific principles underlying it.

Principles of Leather Manufacture. By H. R. Procter. Second edition. E. & F. N. Spon, Ltd., London, 1922. Cloth, 6×10 in., 688 pp., illus., 32 s.

This treatise deals with the general scientific principles of the industry, without describing in detail its practical methods, although many practical points are discussed. The second edition, issued after an interval of eighteen years, has been thoroughly revised, so that the new points of view occasioned by the advances in physical and colloidal chemistry are covered. The volume is intended for chemists and practical tanners.

Principles of Interchangeable Manufacturing. By Earle Buckingham. First edition. Industrial Press, New York; Lond., Machinery Publishing Co., Ltd., London, 1921. Cloth, 6×9 in., 254 pp., illus., diagrams, $3.

In this treatise the author first takes up the general principles involved in interchangeable manufacturing, and then devotes a chapter to the definition of the terms used. The influence of interchangeable processes on machine design and the purpose of models are then dealt with, and followed by a detailed discussion of the dimensioning of drawings for use in interchangeable manufacturing. This is followed by an account of the principal elements that govern economical production, the equipment required, the gage equipment and the principles of inspection and testing. Special chapters treat manufacturing for selective assembly, small-quantity methods and the service factor in interchangeable manufacturing.

Steam Turbines. By William J. Goudie. Second edition. Longmans, Green and Co., London and New York, 1922. Cloth, 6×9 in., 804 pp., plates diagram., illus. $10.

This book has been written primarily to suit the requirements of engineering students, but the author hopes that the methods of calculation outlined in it will be useful also to engineers engaged in the design or operation of steam turbines. The first portion of the text is devoted to detailed descriptions of commercial representatives of the various types now on the market. The second portion treats what may be termed the "technical" part of the subject; nozzles, blading, rotors, gearing, steam consumption, proportions, governing, etc. This edition has been completely rewritten and enlarged.

Uber die Festigkeitsberechnung von Schiebetoren und Ahnlichen Bauwerken. By Adolf Eggenschwyler. H. A. Ludwig Degener, Leipzig, 1921. Paper, 6×9 in., 148 pp.

This monograph discusses the problems in statics involved in the design of sliding sluice gates, floating docks, movable weirs and similar hydraulic structures composed of steel plates and frames. The statical problems that they present are, according to the author, midway between those of bridge building and shipbuilding; and have until now been much neglected. In consequence, the calculations of designers have been based on false assumptions, which have frequently led to an extravagant use of material and to lack of the necessary strength.

THE ENGINEERING INDEX

(Registered United States, Great Britain and Canada.)

THE ENGINEERING INDEX presents each month, in conveniently classified form, items descriptive of the articles appearing in the current issues of the world's engineering and scientific press of particular interest to mechanical engineers. At the end of the year the monthly installments are combined along with items dealing with civil, electrical, mining and other branches of engineering, and published in book form, this annual volume having regularly appeared since 1906. In the preparation of the Index by the engineering staff of The American Society of Mechanical Engineers some 1200 technical publications received by the Engineering Societies Library (New York) are regularly reviewed, thus bringing the great resources of that library to the entire engineering profession.

Photoprint copies (white printing on a black background) of any of the articles listed in the Index may be obtained at a price of 25 cents a page. When ordering photoprints identify the article by quoting from the Index item: (1) Title of article; (2) Name of periodical in which it appeared; (3) Volume, number, and date of publication of periodical; (4) Page numbers. A remittance of 25 cents a page should accompany the order. Orders should be sent to the Engineering Societies Library, 29 West 39th Street, New York.

ABRASIVE WHEELS

Nomenclature. Grinding Wheel Nomenclature, H. A. Plusch. Machy. (N. Y.), vol. 28, no. 12, Aug. 1922, pp. 979–980, 1 fig. Brief description of various types of wheels.

ABRASIVES

See EMERY PAPER.

ACCOUNTING

Industrial. Present-Day Problems in Industrial Accounting, Stanley G. H. Fitch. Jl. of Accountancy, vol. 34, no. 1, July 1922, pp. 1–10. Balance-sheet and its connection with profit-and-loss statement; gives various other features of industrial accounting.

AERONAUTICAL INSTRUMENTS

Air-Speed Indicators. Air-Speed Indicators, Franklin L. Hunt. Nat. Advisory Committee for Aeronautics, Aeronautic Instruments Section III, Report no. 127. Description of typical instruments; altitude correction charts; wind-tunnel, static and flight tests; ground-speed measurements.

AIR COMPRESSORS

Centrifugal. Centrifugal Compressors (Les compresseurs centrifuges), Robert Huguenin. Technique Moderne, vol. 14, no. 6, June 1922, pp. 241–250, 10 figs. Characteristics of centrifugal compressors for mines. Tests with compressors at Orange-Nassau mines.

High-Pressure. Calculation of High-Pressure Compressors (Berechnung von Hochdruck-Kompressoren), P. Ostertag. Zeit. des Vereines deutscher Ingenieure, vol. 66, no. 25, June 24, 1922, pp. 649–650, 3 figs. Gives entropy diagram of a multiple-stage piston compressor for a given final pressure for finding pressure, temperature and volume conditions; calculates cylinder dimensions.

Intercooling. Compressor Intercooler Complication, Frank Richards. Power Plant Eng., vol. 26, no. 13, July 1, 1922, pp. 669–670, 2 figs. Moisture in air at different stages of compression.

Transformers. Air Transformer Shows Remarkable Efficiency, D. M. McLean. Power House, vol. 15, no. 11, July 20, 1922, pp. 25–26, 5 figs. Description of device for blowing forge fires and similar purposes.

[See also TURBO-COMPRESSORS.]

AIR CONDITIONING

Air Purifier. The "Vigoratair" System of Air Purification Eng. Production, vol. 5, no. 95, July 27, 1922, p. 82, 1 fig. Description of details of "portable" air purifier for factory ventilation See also Machy. (Lond.), vol. 20, no. 510, July 6, 1922, pp. 437–438, 2 figs.

Cooling Buildings. Cooling of Theatres and Public Buildings, Fred Wittenmeyer. Ice & Refrigeration, vol. 63, no. 1, July 1922, pp. 13–14. Capacities for and methods of cooling theaters; test on air-cooling apparatus at Blackstone Hotel; costs.

AIRCRAFT

Structural Strength. Structural Strength of Aircraft. Flight, vol. 14, no. 27, July 6, 1922, pp. 385–386. English certificates of airworthiness to be granted only to design meeting specifications in tables shown for general class and for commercial class.

Testing to Destruction. Testing Aircraft to Destruction, Wm. D. Douglas. Aeronautical Jl., vol. 26, no 138, June 1922, pp. 195–222 and (discussion) 222–230, 36 figs. Examples of certain types of defects which are revealed by strength tests. Necessity for supplementing calculations. Description of present methods.

AIRPLANE ENGINES

Air-Cooled Radial. The Siddeley Air-Cooled Radial Engines. Aeroplane, vol. 23, no. 3, July 19, 1922, pp. 43–44 and 46, 8 figs. 7- and 14-cylinder engines developing respectively 160 and 320 hp.; gives data of tests.

The Armstrong-Siddeley "Jaguar" Radial Aero Engine. Flight, vol. 14, no. 29, July 20, 1922, pp. 407–410, 10 figs. 14 cylinders disposed in two rows; outfit rated 350 hp.; cylinders have aluminum heads and steel barrels.

Wright. New Wright Engines for Naval Aviation. Aviation, vol. 13, no. 5, July 31, 1922, pp. 124–125, 2 figs. Brief description and data of tests of Wright model E2, 180-hp. engine, and Wright model T2 525-hp. heavy-duty engine.

Wright-Navy Twelve Reflects Progress in Aircraft Engine Design, Herbert Chase. Automotive Industries, vol. 47, no. 2, July 13, 1922, pp. 57–61, 5 figs. Dependability over long periods of operation is combined with low fuel consumption and unusual degree of accessiblity. Engine develop 525 hp. but has same overall length as Liberty-twelve. Open end sleeve used and babbitt bearings eliminated.

AIRPLANES

De Havilland. The D. H. 37. Aeroplane, vol. 23, no. 4, July 26, 1922, pp. 65–67, 12 figs. Three-seater tractor biplane; Rolls-Royce "Falcon" engine.

Bleriot Spad 45. The Bleriot Spad 45 Four-Engined Airliner, John Jay Ide. Aviation, vol. 13, no. 1, July 3, 1922, p. 13, 1 fig. French airplane fitted with four 275-hp. Hispano-Suiza engines accomodates 17 passengers and crew of 3; high speed, 124 m.p.h.

Commercial. The Bellanca CF 5-Seater Cabin Airplane. Aviation, vol. 13, no. 7, Aug. 14, 1922, pp. 183–185, 2 figs. Commercial airplane designed to carry 5 people with fuel for 600-mile flight.

The Design of a Commercial Aeroplane, G. De Havilland. Aeronautical Jl., vol. 26, no. 139, July 1922, pp. 204–211 and (discussion) 211–218. Consideration of this type of engine; construction; stability; passenger accomodations; gasoline systems; controls.

Handasyde Monoplane. The Handasyde Monoplane, Type H. 2. Flight, vol. 14, no. 29, July 20, 1922, pp. 412–416, 16 figs. Describes new cantilever-type machine with novel wing construction.

Landing. Landing of Airplanes (L'atterrissage des Avions), Philippe. Aerophile, vol. 30, no. 7–8, Apr. 1–15, 1922, pp. 101–103, 2 figs. Discusses landing operations and makes calculations of forces in question.

Sport. The Entler All-Metal Sporting Cantilever Biplane. Flight, vol. 14, no. 26, June 29, 1922, p. 375, 2 figs. Product of Entler Works, Wilhelmshaven, Germany. Characteristics: Span (top) 23 ft., (bottom) 19 ft. 6 in.; chord (top) 4 ft., (bottom) 3 ft. 3 in.; length 16 ft. 9 in.; height 7 ft. 9 in ; weight empty, 375 lb.; area main planes, 150.6 sq. ft.; designed speed 80 m.p.h.

The Heath Sport-'Plane. Flight, vol. 14, no. 27, July 6, 1922, p. 381, 3 figs. Single-seater tractor biplane fitted with 20-hp. 2-cylinder Thor air-cooled motorcycle engine.

The Udet Sporting Single-Seater. Flight, vol. 14, no. 28, July 13, 1922, pp. 394–394, 4 figs. Single seater German monoplane of cantilever type equipped with 30–40-hp. Haacke engine.

Strength Calculator for Details. A Strength Calculator for Aeroplane Details. Flight, vol. 14, no. 23, June 8, 1922, p. 330, 2 figs. Description of slide rule for quickly determining sizes of wiring lugs, bracing attachments, bolts, pins, etc.

AIRSHIPS

Stability. The Stability of Airships: Trials with the R33. Indian Eng., vol. 71, no. 23, June 10, 1922, pp. 326–328, 2 figs. Head-on flight; curvilinear flight and results from model attached to a whirling arm and rotated in water.

[See also PARACHUTES.]

ALLOY STEELS

Decomposition of Martensite in. The Decomposition of Martensite Into Troostite in Alloy Steels, Howard Scott. Forging & Heat Treating, vol. 8, no. 7, July 1922, pp. 296–299, 3 figs. Only manganese, silicon and chromium show marked effect; first increased intensity of transformation, last two raised its temperature in certain percentages.

Tests. Heat Tests with Special Steels (Warmversuche mit Sonderstählen), H. Edert. Stahl u. Eisen, vol. 42, no. 25, June 22, 1922, pp. 961–968, 18 figs. Results of tests made with refined, low-percentage chrome-nickel, chrome-vanadium and non-rustable steels. Investigation includes chemical composition, tensile tests, measurements up to maximum temperature of 800 deg. cent., bending tests up to 600 deg., Brinell tests up to 300 deg. and notched-bar tests up to 700 deg.

ALLOYS

Aluminum. See ALUMINUM ALLOYS.

Diamond. Diamond Alloy—A New Cutting Metal. Machy. (N. Y.), vol. 28, no. 12, Aug. 1922, pp. 958–959, 2 figs. Alloy composed mainly of chromium, molybdenum and tungsten used for making cutting tools.

High-Resistance. Lecfurite—High Resistance Alloy. Machy. (Lond.), vol. 20, no. 511, July 13, 1922, pp. 452–455, 5 figs. Description of new alloy metal fusing at 1,550 deg. cent. and intended for use as resistance wire.

Magnesium. See MAGNESIUM ALLOYS.

[See also BEARING METALS; MONEL METAL.]

ALUMINUM

Casting. Aluminum Casting and Metal Spraying (Vom Aluminium- und Spritzguss). Zeit. für die gesamte Giessereipraxis, vol. 43, no. 28, July 22, 1922, pp. 393–395. Operations in production of aluminum castings and metal for metal spraying.

ALUMINUM ALLOYS

Properties. Improving Aluminum Alloys (Studien an vergütbaren Aluminiumlegierungen), W. Fraenkel and E. Scheuer. Zeit. für Metallkunde, vol. 14, nos. 2 and 3, Feb. and Mar. 1922, pp. 49–58 and 111–118, 15 figs. Processes of improving aluminum alloys with magnesium content; measuring their conductivity, elasticity, e.m.f., velocity of dissolution; determination of density; experiments with alloys containing Mg; change of tensile strength on prolonged heating; effect of tempering; corrosion.

AMMONIA

Synthetic. New Processes and Proposals for the Production of Synthetic Ammonia (Neue Verfahren

und Vorschläge zur synthetischen Gewinnung des Ammoniaks), A. Sander. Zeit. für komprimierte u flüssige Gase, vol. 22, nos. 1, 3 and 4, 1922, pp 1-3, 29-32 and 41-43, 2 figs. No. 1: Discusses Haber and Claude processes, and the Hyper-compressor, with which pressures of 1,000 atmos are reached. No. 2: Discusses Claude process as stated in German patent 341,230, and describes apparatus. No. 3: Production of synthetic ammonia in England, America and other countries.

The Synthesis of Ammonia by Means of High Pressures (La Synthèse de l'Ammoniaque par les Hyperpressions), Georges Claude. Société Industrielle de l'Est, Bul. No. 165, Apr.-June 1922, pp 46-63, 13 figs. partly on supp. plates. Discusses Haber process, simple way of producing high pressures, work of Linde.

AUTOMOBILE ENGINES

Carburetors. See CARBURETORS.

Chain Front-End Drive. Marked Increase in Use of Chains for Front End Drives, J. Edward Schipper. Automotive Industries, vol. 47, no. 1, July 6, 1922, pp. 8-10, 8 figs. New and original drive layouts permit easy adjustment and cause extensive use of this system.

Crankcase-Oil Dilution. The Crankcase Oil Dilution Problem and Its Solution, Wm. F. Parish. Soc. Automotive Engrs. Jl., vol. 11, no. 1, July 1922, pp. 33-47, 14 figs. Incompletely vaporized fuel leaks into crankcase and dilutes oil thereby decreasing its viscosity; carbon-forming properties of oils and effect of heavy oil on engine efficiency; crankcase oil regeneration.

Crankshafts. See CRANKSHAFTS.

Cylinders. See CYLINDERS.

Manufacture. Manufacturing Practice on Light Motor-Car. Power Units. Machy. (Lond.), vol. 20, no. 512, July 20, 1922, pp. 473-477. Methods of Hotchkiss et Cie, Coventry, deals with heat treatment, case-hardening and refining of steels used.

Oil Regeneration. New Plan Regenerates Motor Oil Continuously as Automobile Runs, William F. Parish. Nat. Petroleum News, Vol. 14, no. 27, July 5, 1922, pp. 49-50, 3 figs. Gross crankcase refiner for automatically removing fuel and water dilutions and filtering out foreign substances. From paper read before Soc. Automotive Engrs.

Piston Rings. See PISTON RINGS.

Radiators. Seam Lock is Feature of New Radiator Construction, B. M. Ikert. Automotive Industries, vol. 47, no. 2, July 13, 1922, pp. 66-67, 5 figs. Sections held together by lock; solder acts merely as seal, brass or copper used in making up core is not stretched during construction. Novel machinery utilized in manufacture. Core specially adapted to motor-truck use. Not injured by freezing.

Sleeve-Valve. 10-Hp. Sleeve-Valve Motor-Car Engine. Engineering, vol. 113, no. 2942, May 19, 1922, p. 618, 3 figs. Two-cylinder, horizontally-opposed type made by Vulcan Motor and Eng. Co. which develops 15 b.hp. at 2000 r.p.m.

Straight-Eight Type. The Lessons of Indianapolis, Autocar, vol. 48, no. 1392, June 24, 1922, pp. 1082-1084, 3 figs. Straight-eight engine proves capable of very high sustained speeds. Remarkably high compression ratios adopted.

AUTOMOBILE FUELS

Alcohol-Benzol Tests. Testing Alcohol-Benzol Fuel, W. F. Bradley. Motor Transport, vol. 35, no. 905, July 3, 1922, pp. 29-30, 3 figs. Results obtained by Paris Omnibus Co. with over a thousand buses running on 50 per cent mixture.

Detonation. Measuring the Tendency of Various Fuels to Knock, Thos. Midgley, Jr., and T. A. Boyd. Automotive Industries, vol. 47, no. 1, July 6, 1922, pp. 23-27, 5 figs. Relative effectiveness of alcohol, benzol and other substances in preventing detonation are determined by more precise methods than used in earlier tests. Results indicate some conclusions reached by Ricardo are in error. Xylidine effective in small amount.

Fractional Distillation. Fractional Distillations of Fuel and How to Make Them, P. S. Tice. Automotive Industries, vol. 47, no. 3, July 20, 1922, pp. 120-126, 5 figs. Shortcomings of present standard apparatus and development of new type which fulfills desirable characteristics.

Preparation. The Hot-Spot Method of Heavy-Fuel Preparation, P. C. Mock and M. E. Chandler. Soc. Automotive Engrs. Jl., vol. 11, no. 1, July 1922, pp. 27-32 and 48, 7 figs. Investigation of means for preparing kerosene and mixtures of heavier oils with alcohol and benzol for fuel in manifold.

Tetralite Benzol. Recent Development in Automobile Fuel (Die neuere Entwicklung der Motorkraftstoffe), Wa. Ostwald. Zeit. für angewandte Chemie, vol. 35, no. 46, June 9, 1922, pp. 278-280. Development of explosion and Diesel engines; combustion and mixing of fuels, detailed description and analyses of Reichskraftstoff or tetralite benzol, a mixture of 50 per cent benzol, 25 per cent tetralin and 25 per cent spirits.

AUTOMOBILES

Bodies. European Efforts to Reduce Car Weights Bring Radical Body Construction, W. F. Bradley. Automotive Industries, vol. 47, no. 1, July 6, 1922, pp. 11-12. Extreme reduction of weight and noise features Weymann system of body building. Lends itself to production at low cost. Lancia builds a four-passenger, 122-in. wheelbase car weighing 1650 lb. complete. Chassis frame members used as body frame members.

Lumber Situation Demands Utilization of New Woods for Bodies, Geo. J. Mercer. Automotive Industries, vol. 47, no. 1, July 6, 1922, pp. 13-15, 1 fig. Increase in number of closed bodies forces use for less expensive woods. Quality not diminished. Scientific study of substitute woods necessary. Cables to supplement strength of wood possible.

Bow "V." The "Bow V" Car. Auto, vol. 27, no. 28, July 13, 1922, pp. 575-577, 7 figs. Light vehicle with air-cooled engine, 4-speed gear, clutch and starter of motorcycle design, and automobile transmission mechanism.

Brake and Clutch Practice. European and American Automotive Brake and Clutch Practice, H. G. Farwell. Soc. Automotive Engrs. Jl., vol. 11, no. 1, July 1922, pp. 67-80, 27 figs. Analysis of types used on 165 cars exhibited at London Automobile Show 1920, and discussion of best known types in United States and Europe.

Creeper Track Car. Good Going over Bad Ground. Motor Transport, vol. 35, no. 906, July 10, 1922, p. 62, 3 figs. Remarkable performance in this country by Citröen-Kegresse creeper track car.

German Postal Administration. Auto Service of the German Postal Administration (Der Kraftwagenbetrieb der Reichspostverwaltung unter besonderer Berücksichtigung des Postreiseverkehrs), Hering. Archiv für Post und Telegraphie, no. 6, June 1922, pp. 173-197, 10 figs. Development of suburban and long-distance postal omnibus service, freight-transportation service, and telegraph construction service; describes automobiles used.

G. W. K. The G. W. K. Car. Auto, vol. 27, no. 29, July 20, 1922, pp. 595-598, 11 figs. Light car with friction drive.

Hotchkiss 18-22 Hp. The 18-22 Hp. Hotchkiss Car. Auto, vol. 27, no. 27, July 6, 1922, pp. 553-556, 13 figs. New model of Parisian vehicle; some modifications from previous design; transmission mechanism.

Light Cars. The Temperino Light Car. Auto, no. 26, vol. 27, June 29, 1922, pp. 533-535, 11 figs. Novel design combined with simplicity, lightness and low fuel consumption; 8-hp. twin-cylindered air-cooled engine.

Nazzaro. The 18-30 Hp. Nazzaro Car. Auto, vol. 27, no. 30, July 27, 1922, pp. 617-620, 11 figs. Italian model with overhead valve gear having supplementary rocker and spring, making operation noiseless.

Springs. See SPRINGS, Manufacture.

Streamline. Streamline Autos (Der Stromlinienwagen), P. Jaray. Motorwagen, vol. 25, no. 17, June 20, 1922, pp. 333-336, 7 figs. New type of construction to reduce air resistance; results of experiments made with it in Zeppelin wind tunnel; fuel consumption, etc.

The New Rumpler Chassis. Automobile Engr., vol. 12, no. 165, July 1922, pp. 194-203, 20 figs. Critical examination of new design; streamline type; six-cylinder engine, cylinders being cast in pairs and grouped fanwise above two-throw crankshaft.

Transmission Gears. Practical Difficulties in Automatic Transmission Gear Design, P. M. Heldt. Automotive Industries, vol. 47, no. 4, July 27, 1922, pp. 164-165, 1 fig. Describes Andreau gear consisting essentially of internal-type planetary gear with operation controlled by pair of centrifugal weights.

Wheels. Camber and Gather Relationships in Front-Wheel Alignment, J. C. Sproull. Soc. Automotive Engrs. Jl., vol. 11, no. 1, July 1922, pp. 91-92 and 116, 4 figs. Effect of tilting of wheel spindles so that wheels lean outward at top, and so as to bring front part of wheels nearer together than rear, and mathematical formulas for determining their proper values.

How Pressed Steel Wheels are Made, J. Edward Schipper. Automotive Industries, vol. 47, no. 2, July 13, 1922, pp. 71-74, 14 figs. Recent machine-tool developments add to manufacturing efficiency; varied nature of presswork shows wide possibilities in pressed-steel production; disk of tapered section is employed.

AVIATION

Aerial Navigation and Instruments. Aerial Navigation and Navigating Instruments, H. N. Eaton. Nat. Advisory Committee for Aeronautics, Report No. 131, 1922, 44 pp., 26 figs. Description of dead-reckoning method; natural and artificial horizons and radio direction finder.

Newfoundland and Labrador. Aviation in Newfoundland and Labrador. Aviation, vol. 13, no. 2, July 10, 1922, pp. 41-43, 3 figs. Practical demonstration of value of aerial mail and passenger transport in Arctic countries.

Safety. Safety in the Air. Aeroplane, vol. 22, no. 26, June 28, 1922, pp. 463-464. Dangers incident to starting, flying, and landing, and suggestions for minimizing same.

B

BALANCING

Rotating Parts. Balancing Rotating Parts (Sur l'équilibrage des pièces tournantes), C. Feru and J. Labouret. Révue Générale de l'Électricité, vol. 11, no. 25, June 24, 1922, pp. 919-926, 12 figs. Balancing on one and two bearings, determination of angle ϕ.

BALLISTICS

Exterior. Exterior Ballistics in Anti-Aircraft Firing and Their Industrial Applications (La balistique extérieure du tir aérien, applications industrielles), Gustave Lyon. Bul. de la Société d'Encouragement pour l'Industrie Nationale, vol. 134, no. 4, Apr. 1922, pp. 327-380, 32 figs. Discusses progress made during war in measuring and determination of trajectories, and describes in detail instruments used. Includes two appendices by Maurie Garnier.

BEAMS

Reinforced-Concrete. Chart for Rapid Calculation of the Minimum Iron Cross Section in Reinforced-Concrete Beams Under Flexure and Compression or Tension (Graphique puor l'obtention rapide des sections de fer minima, dans une poutre en béton armé, soumise à des efforts composés de flexion avec compression ou tension), E. Gardiol. Bul. Technique de la Suisse Romande, vol. 48, no. 10, May 13, 1922, pp. 113-119, 5 figs. Develops formulas and explains use of chart.

T-Beams, Calculation. Charts for Calculating T-Beams Under Flexure (Abaque pour le calcul des poutres en T soumises à flexion simple), R. Coppee. Annales de l'Association des Ingénieures Sortis des Écoles Spéciales de Gand, vol. 12, no. 1, 1922, pp. 49-53, 2 figs. partly on supp. plate. Develops formulas and explains use of chart.

BEARING METALS

Car and Power-House. Metals for Car and Power House Bearings, H. H. Buckman. Elec. Ry. Jl., vol. 60, no. 2, July 8, 1922, pp. 47-48. Some essential characteristics of satisfactory bearing metal; advantages of using lead base metal. (Abstract.) Paper read before Central Elec. Ry. Assn.

BEARINGS

Casting. Foundry Practice (La Pratique du Régulage), M. Verneret. Fonderie Moderne, nos. 4 and 5, Apr. and May 1922, pp. 97-99, and 143-152, 15 figs. Apr.: Operations connected with casting anti-friction metals direct on to bearing surfaces; nature and choice of anti-friction metals and alloys. May: Utilization of scrap; remelting of metal; fluxes and oxidizing agents; casting; etc.

BEARINGS, BALL

Design. Load on Ball Bearings (Kugelagrets Belastning), F. Symanzik. Teknisk Ukeblad, vol. 69, no. 23, June 9, 1922, pp. 216-218, 3 figs. New method for determining size of ball bearings; examples and calculations.

Flour-Mill Equipment. Saving Power in Minnesota Mill. Am. Miller, vol. 50, no. 7, July 1, 1922, pp. 719-720, 5 figs. Ball-bearing equipment of Hubbard Milling Co., Mankato; installation of SKF ball bearings on lineshafts which accomplished estimated saving of $3,250 first year.

Roller and. Ball and Roller Bearings in Street-Car Operation and Small Factories (Kugel- und Rollenlager im Strassen- und Kleinbetrieb), Carl Tobias. Zeit. des Österr. Ingenieur- u. Architekten-Vereines, vol. 74, nos. 11-12 and 15-16, Mar. 17 and Apr. 14, 1922, pp. 55-56, and 69-71, 5 figs. Mar. 17: Experiments with ball and roller bearings for railway rolling stock; lubrication and its relative cost. Apr. 14: Discusses advantages in saving of lubricants and attention.

BEARINGS, ROLLER

Design and Construction. Rolling Contact Bearings, Tobias Dantzig. Steam, vol. 30, no. 1, July 1922, pp. 3-7. Important requirements of efficiency, capacity, long life, operation at high speed, self-alignment, and ability to maintain permanent clearance. Means of attaining each. Read before Cincinnati Section A.S.M.E.

BLAST FURNACES

Sulphur Excess in Slag. Blast Furnaces Difficulties Due to Excessive Sulphur in Slag (Ueber noch wenig bekannte Schwierigkeiten im Hochofen durch "Schwefelelend"), A. Killing. Stahl u. Eisen, vol. 42, no. 25, June 22, 1922, pp. 968-971, 3 figs. Practical observations with sulphur-rich slag. Injurious effect of sulphur on blast-furnace process. Remedies.

BLOWERS

Blast-Furnace Centrifugal. Centrifugal Blast-Furnace Blowers. Iron & Coal Trades Rev., vol. 104, no. 2833, June 16, 1922, pp. 896-897, 5 figs. Turbo-blowers producing pressures up to 40 lb. per sq. in. and turbo-compressors for higher pressures both transform for energy, half into direct compression and half kinetic energy. Many blast-furnace requirements.

BOILER FEEDWATER

Treatment. A Criticism of the Various Methods of Purifying Feedwater (Kritik der verschiedenen Methoden der Reinigung von Kesselspeisewasser), B. Preu. Dinglers polytechnisches Jl., vol. 337, nos. 1 and 2, Jan. 14 and 29, 1922, pp. 1-4 and 11-13. Jan. 14: Reviews efficiency of lime-soda method, the permutite method, Neckar method, and others. Jan. 29: Describes new method by Ph. Müller and the apparatus, and calculates its efficiency.

Continuous Blowdown and Water Purification Process, M. Kestner. Power Plant Eng., vol. 26, no. 13, July 1, 1922, pp. 647-652, 10 figs. Method of precipitating impurities outside of boiler without loss of heat. (Abstract.) Paper read before British Inst. Mech. Engrs.

Softening of the Boiler Feedwater (Enthärtung des Kesselspeisewassers), P. Martiny. Archiv für Wärmewirtschaft, vol. 3, no. 6, June 1922, pp. 103-110, 7 figs. Action of carbonic acid and oxygen; formation of incrustation and its remedy; describes principal processes of treating water.

BOILER OPERATION

Firing With Low-Grade Fuels. Hints on Firing

With Low-Grade Fuels and Adapting Furnaces for Such Fuels (Winke zur Verheizung von minderwertigen Brennstoffen und zur Umstellung der Feuerungen auf solche Brennstoffe), Schnell. Zeit. des Bayerischen Revisions-Vereins, vol. 26, no 12, June 30, 1922, pp. 95–98. Temporary and permanent adaptation of furnaces of steam boilers of various types; ratio of grate surface to heating surface, mixture of fuels

Grate Charge. Dependence of Grate Charge on Moisture Content of Fuel (Die Abhangigkeit der Rostbelastungen vom Wasserstoffgenalt des Brennstoffes), W. Viebahn. Braunkohle, vol. 21, no. 13, June 30, 1922, pp. 258–262, 3 figs. Discusses so-called grate load, i.e., number of kg. of fuel burned per hr. per sq. m. of grate surface, and discusses this load for lignite and coal containing different percentages of water.

Humidity and Barometric-Pressure Effects. Effect of Humidity and Barometric Pressure on Boiler Efficiency (Der Einfluss der Luftfeuchtigkeit und des Barometerstandes auf den Kesselwirkungsgrad), L. Finckh. Wärme, vol. 45, no. 23, June 9, 1922, pp. 283–285. Quantity and temperature of air for combustion for lignite, coal and peat; gives table of comparative figures.

[See also PEAT; PULVERIZED COAL, Boiler Firing.]

BOILERS

Electrically Heated. Regulating Electrode Steam Boilers (Die Leitsungsregelung von Elektrodendampfkesseln), Edgar Zeulmann. Elektrotechnische Zeit., vol. 43, nos. 22 and 23, June 1 and 8, 1922, pp. 759–762 and 784–788, 27 figs. Describes best-known types of electrode steam boilers in which boiler water itself forms electric resistance, and gives their advantages and disadvantages, methods of regulation, etc.

Report on an Investigation of an Electric Boiler Installation (Bericht uber die Untersuchung einer Elektrokesselanlage). Zeit. des Bayer. Revisions-Vereins, vol. 26, no. 10, May 31, 1922, pp. 85–86, 3 figs. Detailed description of boiler installation of a textile spinning and weaving establishment at Blaichach, working on 1000-kw. polyphase current at 510 volts, which has given entire satisfaction.

Maintenance. Recommendations on Boiler Maintenance, A. G. Pack. Ry. Jl., vol. 28, no. 8, Aug. 1922, pp. 19–21. Data from practical experience and suggestions. Welding employed where other means of construction could be more profitably employed. Author is chief inspector of locomotive boilers for U. S. Government.

Testing. The Question of Accurate Boiler Tests, Alfred Cotton. Power House, vol. 15, no. 14, July 20, 1922, pp. 17–20, 2 figs. Attempt to establish accuracy of tests; discussion of various items involved.

BRAKING

Freight-Train. Application of the Continuous Brake to Freight Trains in Tunis (Une application du frein continu aux trains de marchandises en Tunisie), Louis Tronchère. Révue Générale dès Chemins de Fer et des Tramways, vol. 41, no. 1, July 1922, pp. 3–11, 4 figs. Describes tests made in 1909 by Gafsa Co. on Sfax-Redeyel line, and gives rules adopted for equipment and operation.

Regenerative. An Analysis of Regenerative Braking on Electric Locomotives, C. E. Fairburn and F. A. Harper. English Elec. Jl., vol. 2, no. 2, Apr.-July, pp. 68–77, 5 figs. Mathematical analysis, with curves.

BUILDING MATERIALS

Testing Machines. New Machines for Testing Building Material. Eng. Progress, vol. 3, no. 7, July 1922, pp. 157–158, 6 figs. Exhibition at last Spring Fair at Leipsic of testing machines for cement and other construction materials which have remarkable constructional features.

BUSES

Trolley. A New English Trolley Bus. Bus Transportation, vol. 1, no. 7, July 1922, pp. 379–380, 4 figs. Vehicle designed from experience with gasoline road vehicles; single motor is used and automatic control features are provided to facilitate quick acceleration. Easy coasting and safe operation generally.

Notes on Railless Electric Traction, E. M. Munro. Tramway & Ry. World, vol. 51, no. 29, June 15, 1922, pp. 287–295, 15 figs. Analysis of principles involved. Data from types of cars in daily service and comparison with tramcars and motor buses. Paper to be read at Congress of Tramways & Light Rys. Assn.

C

CAMS

Circumference Formula. Formula for Circumference of Portion of Cam. Machy. (Lond.), vol. 20, no. 513, July 27, 1922, pp. 524–525, 1 fig. Mathematical treatment.

CAR COUPLINGS

Screw, Railway. Railway Screw Couplings. Ry. Gaz., vol. 37, no. 2, July 14, 1922, pp. 61–62, 1 fig. Test results of nickel-chrome steel coupling for Bengal Nagpur railway.

CAR LIGHTING

Electric. Principal Systems of Train Lighting (Les principaux systèmes d'éclairage électrique individual appliqués aux voitures de chemins de fer), M. Bougrier. Électrician, vol. 38, no. 1304, July 15, 1922, pp. 313–320, 7 figs. Describes electric systems by Stone, Vicarino, and Aichelé, and their apparatus and operation.

Train Lighting (L'Éclairage des trains), H. Guerin. Génie Civil, vol. 81, nos. 1, 2 and 3, July 1, 8 and 15, 1922, pp. 13–15, 36–40 and 59–63, 25 figs. Substitution of electric lighting for systems in use; development of train lighting and its general principles; Brown-Boveri, Dick-E. V. R., Vickers, Etat-E. V. R., Stone, Leitner, Electric Storage Battery Co., and Société de l'Éclairage des Vehicules sur Rails systems; various types of storage batteries.

CAR WHEELS

Chilled-Iron. Properties of Chilled Iron Car Wheels, George W. Lyndon. Elec. Traction, vol. 18, July 1922, no. 7, pp. 592–594, 2 figs. Association of manufacturers of chilled car wheels and Univ. of Ill. investigate wheel fit and static load strains. Bur. of Standards conducts tests on thermal stresses.

CARBURETORS

Adjustment by Gas Analysis. Carburator Adjustment by Gas Analysis, A. C. Fieldner and G. W. Jones. Jl. Indus. & Eng. Chem., vol. 14, no. 7, July 1922, pp. 594–600, 10 figs. Experimental work on determination of carbon dioxide in exhaust gas, which has direct bearing on carburetor adjustment.

Capac. A New Capac Carburetter. Autocar, vol. 49, no. 1397, July 28, 1922, p. 188, 1 fig. Instrument specially devised for sporting-car engine and to provide rapid acceleration.

CARS, FREIGHT

Gondola, C. M. & St. P. How the C. M. & St. P. R. R. Designed Their New Gondola Cars. Ry. Rev., vol. 70, no. 23, June 10, 1922, pp. 834–841, 11 figs. Analysis of functions of individual members and calculation of stresses involved.

Springs. Spring Assemblages for Freight Car Trucks, Geo. S. Chiles. Ry. Rev., vol. 70, no. 23, June 10, 1922, pp. 844–850, 8 figs. New side frame and bolster design provides higher spring capacity and lower truck weight.

CARS, PASSENGER

6-Wheel Cast-Steel Truck. The Latest Development in 6-Wheel Passenger Trucks. Ry. Rev., vol. 70, no. 23, June 10, 1922, pp. 831–833, 6 figs. Pullman Company adopts new design of commercial type with clasp-brake equipment.

CASE-HARDENING

Steels for. A Comparison of the Rate of Penetration of Carbon into Various Commercial Steels in Use for Case Carburizing, S. C. Spalding. Am. Soc. for Steel Treating Trans., vol. 2, no. 11, Aug. 1922, pp. 950–976, 136 figs. Investigation of straight carbon, chromium-silicomanganese, nickel, chromium, nickel and chromium-molybdenum steels. Curves and photomicrographs.

CAST IRON

Testing Methods. New Methods of Testing Cast Iron, E. V. Ronceray. Metal Industry (Lond.), vol. 20, no. 25, and vol. 21, no. 1, June 23 and July 7, 1922, pp. 586–588 and 13–18, 20 figs. Review of various methods and description of work of Fremont's transverse testing machine. Paper read before Inst. British Foundrymen.

New Methods of Testing Cast Iron, E. V. Ronceray. Foundry Trade Jl., vol. 26, no. 307, July 6, 1922, pp. 5–12, 19 figs. Fremont's transverse testing machine; shearing tests; M. Portevin's test; elastic limit, modulus of elasticity, sounding and ball tests.

CEMENT MANUFACTURE

Electric. Electric Cement, Henry J. Harms, Jr. Concrete, vol. 20, no. 6, June 1922, pp. 113–115. Description of French process for producing cement in an electric furnace; superiority of product.

Iron and Steel Application. Iron and Steel Application to the Cement Industry, W. R. Shimer. Eng. World, vol. 21, no. 2, Aug. 1922, pp. 93–96. Selection of steels for use in handling cement, particularly heat-treated steel for shovels, gyratories.

CENTRAL STATIONS

France. The Great Thermoelectric Central Station at Comines [La grande centrale thermoélectrique de Comines (Nord)], J. Reyval. Révue Générale de l'Électricité, vol. 12, nos. 2 and 3, July 15 and 22, 1922, pp. 55–68 and 93–105, 34 figs. July 15: One of the most modern stations; has three 25,000 kw. units giving normal power of 50,000-kw., one unit being spare; describes boiler house, machine room and equipment. July 22: Describes pumping station and water intake, 45,000-v. transmission lines, overhead equipment, and underground equipment.

Superpower. The Bavarian Works and Its Sources of Power (Das Bayernwerk und seine Kraftquellen), A. Menge. Elektrotechnische Zeit., special no. May 28, 1922, pp. 2–20, 30 figs. Object of this works is to supply whole of Bavaria with electric power as economically as possible and for this purpose a 110 kv. transmission line has been built, connecting up Munich, Meitingen, Nurenberg, Amberg, Regensburg and Landshut lines, describes masts, insulators, general line equipment, transformers, and switching systems.

The Gennevilliers Central Station [La centrale électrique de Gennevilliers (Seine)], Ch. Dantin. Génie Civil, vol. 81, no. 1, July 1, 1922, pp. 1–13, 33 figs. partly on supp. plates. Has 5 groups of turbo-alternators of 40,000 kw. each and 3 in reserve, making total of 320,000 kw. Describes buildings, boiler house, stoking, ash handling, turbines and alternators, high-tension cables, switchboards, etc.

CERIUM

Effect on Brass and Iron. Adds Cerium to Brass and Iron, L. W. Spring. Foundry, vol. 50, no. 13, July 1, 1922, pp. 542–544, 2 figs. Effect on red brass is to increase percentage of leaky castings and lower tensile strength and ductility. Shows marked effect on converter steel and causes gray iron to feed better. Paper prepared for convention of Am. Foundrymen's Assn.

CHROMIUM STEEL

Chromium Determination. Rapid Methods for the Determination of Chromium in Steel, A. S. Townsend. Forging & Heat Treating, vol. 8, no. 7, July 1922, pp. 304–305. Oxidation of chromium in acid solution to chromic acid; bibliography.

COAL

Briquetting. Briquetting of Dutch-Indian Coal and Lignite (Briketteering van Indische steen- en bruinkolen), A. Guyot van der Ham. Ingenieur, vol. 37, no. 27, July 8, 1922, pp. 515–523 and (discussion), 523–626, 1 fig. Methods and operations of Sawah Loento briquetting factory, using pitch as binding medium.

Drying. Hoyle Centrifugal Dryer at Tinsley Park Coke Ovens. Colliery Guardian, vol. 123, no. 3209, June 30, 1922, p. 1603, 2 figs. Apparatus in which coal flung outward by centrifugal force against screens passes down as thin film on inner surfaces of screen while moisture goes through.

COAL HANDLING

Ash and. Economical Handling of Coal and Ashes, Henry J. Edsall. Can. Manufacturer, vol. 42, no. 7, July 1922, pp. 23–26, 2 figs. Great savings made from installations and recent developments.

Modern Coal and Ash Handling Plant. Gas Engr., vol. 38, no. 554, June 15, 1922, pp. 155–158, 9 figs. Advantages and disadvantages of various types and general points for consideration.

Pneumatic. The Pneumatic Handling of Coal, H. Blyth. Gas Engr., vol. 38, no. 554, June 15, 1922, pp. 151–154, 5 figs. Conditions under which satisfactory results may be expected and details of successful installation.

COLD STORAGE

Research Laboratory. Cold Storage Research Laboratory. Ice & Refrigeration, vol. 63, no. 2, Aug. 1922, pp. 93–97, 6 figs. Description of laboratory at Canton, Pa., established for purpose of carrying on experiments and research work in storage of perishable products.

COKE

Analysis. The Analysis of Coke, Arthur Grounds. Iron & Coal Trades Rev., vol. 104, no. 2835, June 30, 1922, p. 977. Sampling, moisture, ash, sulphur, phosphorus, calorific value.

Economy for Steam Fuel. Economy of Coke for Steam Fuel. Gas Age-Rec., vol. 50, no. 4, July 22, 1922, pp. 107–108. Coke at $6 cheaper if properly burned for steam raising than coal at $7.

COKE MANUFACTURE

Metallurgical. Production of Metallurgical Coke (Die Erzeugung von Hüttenkoks aus nicht backenden Kohlen), M. Dolch. Glückauf, vol. 58, no. 25, June 24, 1922, pp. 772–776. Experiments for producing good coke from coal which cakes poorly or not at all.

Non-Coking Coals. Good Coke Now Manufactured from Non-Coking Coals of Illinois, with Saving of Byproducts, H. A. Patterson. Coal Age, vol. 22, no. 2, July 13, 1922, pp. 45–50, 5 figs. Seeks to coke coal before cementing material is oxidized; heat graduated to suit thickness of bed to be coked; coking time lowered to twelve hours; gas introduced at two levels. (Abstract.) Paper read before Ill. Min. Inst.

Theory. A Recent Theory of Coking, F. V. Tideswell. Fuel in Science & Practice, vol. 123, no. 3208, June 23, 1922, pp. 101–103. Discussion of theory underlying improved process which claims to include bituminous and non-bituminous non-coking coals in coking coals.

COKE OVENS

Heating with Blue Water Gas. Heating Coke Ovens with Blue Water-Gas, J. F. O'Malley. Chem. & Met. Eng., vol. 27, no. 2, July 12, 1922, pp. 75–78, 6 figs. Doubles surplus gas from ovens; eliminates carbon from heating flues and permits uniform oven operation without change of burners.

Path of Gas Travel. The Foxwell Theory of the Path of Travel of the Gases in the Coke Oven. Gas World, vol. 76, no. 1976, June 3, 1922, p. 10, 1 fig. Laws controlling path found to be similar to those for nest of capillary tubes. Discussion of application of theory.

COMBUSTION

Gas Distribution. Study of Distribution of Combustion Gases. Am. Gas Jl., vol. 117, no. 5, July 29, 1922, pp. 89–91, 7 figs. Description of new method of studying diffusion of heat in various apparatus and distribution of combustion gases by means of properties of colored smoke. Model tests compared with phenomena in apparatus in actual operation. From "High-Pressure Boilers" by H. Thoma, Berlin.

Spontaneous. Spontaneous Combustion, Walter L. Wedger. Safety, vol. 9, no. 7, July 1922, pp. 163–168, 1 fig. Various causes and attempts at prevention. Apparatus for testing tendency of cloth. From paper read before Mass. Safety Council of Nat. Safety Council

COMPASSES

Gyroscopic. Theory of the Gyroscopic Compass (Theorie du compas gyroscopique), P. Lemaire. Technique Moderne, vol. 14, no. 5, May 1922, pp. 202–205, 2 figs. Describes construction and operation and makes calculations in connection with it.

COMPRESSED AIR

Storage. Compressed Air Power Storage (Kraft-Speicherungs-Anlagen mittels komprimierter Luft), W. E. Trampler. Schweizerische Bauzeitung, vol. 79, no. 17, Apr. 29, 1922, pp. 222–224, 7 figs. Discusses pneumatic accumulation in place of hydraulic accumulation by compressing air into heat-insulated storage tanks ready for any power use.

CONDENSERS, STEAM

Design. Steam Condensing Plant, D. I. Hall. Beams, vol. 10, no. 6, June 1922, pp. 427–436, 4 figs. Items to which careful consideration must be given in designing surface condensers and jet condensers; air leakage and air pumps; condensate pump; plant arrangement.

CONVEYORS

Belt. Essentials of a Serviceable Belt Conveyor, Omega. Eng. & Indus. Management, vol. 7, no. 18, July 13, 1922, pp. 583–589, 9 figs. Notes on design and various elements.

Cotton Mill. Conveyors at Great Falls Manufacturing Company, Ernest Fallows. Textile World, vol. 62, no. 1, July 1, 1922, pp. 67 and 69, 5 figs. Equipment installed for mechanical handling of stock in new 3-story concrete cotton mill at Somersworth, N. H. Advantages are shown in labor saving and better condition of material during manufacture.

CORROSION

Prevention. Fighting Corrosion as a Major Source of Waste in Industry, R. H. Hubbed. Jl. Elec. & West. Industry, vol. 49, no. 1, July 1, 1922, pp. 9–11, 7 figs. Choice of proper coating; paints that injure metal.

Mechanism of Metallic Oxidation at High Temperatures, N. B. Pilling and R. E. Bedworth. Chem. & Met. Eng., vol. 27, no. 2, July 12, 1922, pp. 72–74. Rapidity due to combination of physical properties of oxide and its ability to absorb and diffuse oxygen rather than to any property of metal itself. Paper read before Am. Inst. Min. & Metallurgical Engrs.

Oxidation of Steels and Their Use in Degasification of Water (Sur l'oxydabilité des aciers et leur utilisation au dégazage de l'eau), G. Paris. Chaleur et Industrie, vol. 3, no. 25, May 1922, pp. 1259–1261, 1 fig. Discusses dependence of oxidation of steels on their crystalline structure, and proposes special alloys for fixing oxygen in water.

CRANES

Ship. The New Ship Crane for the Navy, A. F. Case. Tech. Eng. News, vol. 3, no. 3, June 1922, pp. 71, 85, 89 and 91, 2 figs. Contract has been awarded by Navy for construction of 250-ton revolving crane, to be mounted on U. S. battleship Kearsarge, largest sea-going crane ever constructed.

Slewing. Slewing Cranes (Grues roulantes et pivotantes sur portique). Bul. Technique de la Suisse Romande, vol. 48, no. 15, July 20, 1922, pp. 174–178, 2 figs. Describes electrically driven crane for dock purposes with 50-ton per hr. capacity and 4500 kg. load.

Traveling. Lifting Apparatus (Appareils de levage), Legrand-Ribet. Outillage, vol. 6, nos. 24 and 25, June 17 and 24, 1922, pp. 765–767, and 787–791, 9 figs. June 17: Calculations and specifications of an electric traveling crane of 10,000 kg. capacity at 20 m. radius of action, with hoisting speed of 6 m. per min. June 24: Describes framework of crane and calculations for it.

CRANKSHAFTS

Manufacture. Making the Marmon Crankshaft, Fred B. Jacobs. Abrasive Industry, vol. 3, no. 7, July 1922, pp. 199–204, 10 figs. Accuracy and quantity production are assured by modern grinding machines and abrasive wheels; shafts must be balanced accurately.

CUTTING TOOLS

See ALLOYS, Diamond.

CYLINDERS

Automobile, Casting. Casting Chevrolet Cylinders. Foundry, vol. 50, no. 14, July 15, 1922, pp. 565–569 and 579, 6 figs. Details of core making, venting, method of setting and adjusting cores, together with general features involved in making mold; equipment is adequate.

D

DIES

Self-Opening, Chasers for. Making Chasers for Self-opening Dies. Am. Mach., vol. 57, no. 5, Aug. 3, 1922, pp. 169–171, 16 figs. Milling blocks to form and use, cutting threads by means of hobs; hand and machine tapping methods.

DIESEL ENGINES

Design. Variations in Modern Diesel-Engine Design, Thos. Orchard Lisle. Soc. Automotive Engrs. Jl., vol. 11, no. 1, July 1922, pp. 92–106, 36 figs. Unfavorable comments on tendency to depart from original Diesel designs.

Fuel Oil, High-Viscosity. Boiler-Oils for Diesel Power, L. B. Jackson. Motorship, vol. 7, no. 7, July 1922, pp. 528–530, 4 figs. Valuable development work in use of fuel oils for motorships carried out by Texas Co.

Valves. Care of Valves on Diesel Engines, L. R. Ford. Power, vol. 56, no. 6, Aug. 8, 1922, pp. 204–206, 4 figs. General discussion.

Werkspoor. British Construction of Werkspoor Diesel Engines. Motorship, vol. 7, no. 8, Aug. 1922, pp. 607–612, 8 figs. Motors built by North Eastern Mar. Eng. Co. for single-screw fruit-carrying vessels, Segona and Seville.

DIRECTION FINDERS

Navigation. Radio Direction Finding, F. W. Dunmore. Pacific Mar. Rev., vol. 19, no. 7, July 1922, pp. 404–407. Methods of radio direction finding as aid to navigation; relative advantages of locating finder on shore and on shipboard.

DRILLING MACHINES

Design. Effect of Design on Drilling Machine Efficiency, F. E. Johnson. Machy. (N. Y.), vol. 28, no. 12, Aug. 1922, pp. 964–967, 6 figs. Important factors in design and operation. Suggestions for improving operative conditions.

DUST

Collection. Designing a Dust-Collecting System, H. M. Nichols. Wood Worker, vol. 41, no. 4, June 1922, pp. 50–51. Principles which must be considered in planning efficient exhaust system for woodworking plant.

Explosions. Progress in Dust Explosion Prevention, David J. Price. Chem. & Met. Eng., vol. 26, no. 26, June 28, 1922, pp. 1203–1206. Flour-milling industry and dust explosions; Federal investigation of dust explosions; summary of dust-explosion losses in various industries; progress of dust collection and removal and adoption of methods of preventing explosions. Paper read at Millers' Federation Mass. Convention.

DYE INDUSTRY

Synthetic. Development of the Synthetic Dye Industry (Le développement de l'Industrie des colorants synthétiques), Eug. Grandmougin. Génie Civil, vol. 80, nos. 22, 23 and 24, June 3, 10 and 17, 1922, pp. 491–494, 517–520, and 543–546. June 3: Development in France; prime materials; intermediates and their production; production of dyes themselves. June 10: Short history of dye industry, production of dyes in various countries. June 17: Future of dye industry generally and of scientific research in connection with it.

DYNAMOMETERS

Brake. Measuring Electric Power by the Brake Dynamometer (Mesure de la puissance des moteurs électriques au moyen des dynamos dynamomètres), M. Marre. Électricien, vol. 53, no. 1300, May 15, 1922, pp. 222–227, 8 figs. Construction and operation of brake dynamometer, its application in testing, friction losses, etc.

E

ECONOMIZERS

Performance. Notes on Economizer Performance, A. W. Binns. Power Plant Eng., vol. 26, no. 14, July 15, 1922, pp. 694–697, 5 figs. Losses, methods of testing, obtaining standards and maintenance.

ELECTRIC FURNACES

Brass and Bronze. Electric Melting Furnaces for Brass and Bronze, Howard McLean and John M. Boyd. West. Machy. World, vol. 13, no. 7, July 1922, pp. 244–246, 4 figs. Commercial uses for electric furnace and description of various types; some considerations of comparative melting costs.

Enameling, Vitreous. Developments in 1921 in Electric Vitreous Enameling Furnaces, James W. Carpenter. Am. Ceramic Soc. Jl., vol. 5, no. 7, July 1922, pp. 409–419, 4 figs. Summary of new installations in 1921 and description of various types of furnaces; operating data.

Resistance. Wire and Ribbon Wound Resistance Furnaces, Charles C. Bidwell. Sibley Jl. of Eng., vol. 36, no. 6, June 1922, pp. 119–121 and 129. Temperature range determines choice of resistor refractory and thermal insulation; temperature distribution determines shape of furnace, manner of winding, heating elements and placing thermal insulation.

Single-Phase. Single-Phase Electric Furnace, H. P. Abel, A. A. Liardet and W. West. Iron & Steel of Canada, vol. 5, no. 7, July 1922, pp. 128–130. Advantages of single-phase furnaces; drawback of bad effect of power factors; details of construction and operation.

Steel. A New French Electric Furnace for Steel Foundry, R. Sylvany. Can. Foundryman, vol. 13, no. 7, July 1922, pp. 28–29. Constructed with idea of insuring good purification by direct passage and uniform distribution of current through metal and slag.

Fiat Electric Steel Furnace, Dr. Alfredo Stromboli. Chem. & Met. Eng., vol. 27, no. 1, July 5, 1922, pp. 28–30, 5 figs. Description of Fiat furnace of large output with tight roof maintained by special economizer.

The New Electric Steel Furnaces of the Fiat Works (Die neuen Elektrostahlöfen der Fiat-Werke), G. Vitali. Stahl u. Eisen, vol. 42, no. 24, June 15, 1922, pp. 921–924, 6 figs. General adoption of electric steel furnaces; principles of Fiat furnace, its construction, including electrodes, control of operations, and results of working.

Sweden. Electric Smelting and Blast-Furnace Installations in Porjus (Sweden) (De elektriska smältverks- och masugnsanläggningarna i Porjus), Gunnar Hetlin. Jernkontorets Annaler, vol. 106, no. 4, 1922, pp. 99–132, 22 figs. Detailed description of plant layout, buildings, electrical and other equipment, furnaces, etc.

ELECTRIC LOCOMOTIVES

Swiss. Single Phase Express Locomotives 2-C-1 With Individual Axle Drive of the Brown-Boveri Type (Einphasen Schnellzuglokomotiven 2-C-1 mit Einzelachsantrieb Bauart Brown Boveri). Schweizerische Bauzeitung, vol. 80, no. 2, July 8, 1922, pp. 13–17, 12 figs. partly on supp. plate. Describes locomotives of Swiss federal railways, including distribution of weight, individual axle drive, cog-wheel arrangement, etc.

2-8-2 Mikado. New Electric Locomotives of the Orleans Railway (Nouvelles locomotives électriques du chemin de fer d'Orleans). Industrie Électrique, vol. 31, no. 718, May 25, 1922, pp. 185–188, 2 figs. Describes new 2-8-2 or Mikado type; 2,000 hp., d.c. at 250 v.; constructed by Electro-Mecanique Co. for Paris-Orleans railway.

ELECTRIC RAILWAYS

Austria. Electric Working of Austrian Railways (Der elektrische Betrieb auf den Oesterreichischen Bundesbahnen), E. E. Seefehlner. Elektrotechnische Zeit., special no., May 28, 1922, pp. 11–14, 5 figs. Discusses hydroelectric developments and describes new single-phase a.c. locomotives 1C + C1.

Germany. Electric Long-Distance Trains of the German State Railways (Mitteilungen aus dem elektrischen Fernzugbetrieb der Deutschen Reichsbahn), W. Wechmann. Elektrotechnische Zeit., vol. 43, nos. 24, 25 and 27, June 15, 22 and July 17, 1922, pp. 805–810, 837–840, and 904–908, 33 figs. Reviews electric traction on German railways; type of current, economics of electrification; results of electric operating of Silesian mountain railways; standardization of locomotives and their control; describes various types of locomotives; compares performance of steam and electric locomotives.

Electric Railroad Communication in Bavaria (Die elektrische Zugförderung im bayerischen Abschnitt der Reichsbahn), B. Gleichmann. Elektrotechnische Zeit., special no., May 28, 1922, pp. 24–32, 14 figs. Discusses railroad agreement between Prussian, Bavarian and Baden roads, traffic conditions, and gives particulars as to electric locomotives used.

Napa Valley, California. The Napa Valley Route. Elec. Ry. Jl., vol. 60, no. 1, July 1, 1922, pp. 7–8, 5 figs. San Francisco, Napa & Calistoga Ry. is successful single-phase California electric system; in connection with boat line it offers through service to San Francisco.

Temperature Effect on Power Consumption. Relation Between Temperature and Power Used by Electric Cars, A. W. Baumgarten. Elec. Ry. Jl., vol. 60, no. 3, July 15, 1922, pp. 77–78, 3 figs. Tests indicate that more power is used during cold weather; present methods of lubrication appear to be responsible for large part of increase.

ELECTRIC WELDING

Electropercussive. Review of Electro-Percussive Welding, D. F. Miner. Am. Welding Soc. Jl., vol. 1, no. 7, July 1922, pp. 27–36, 36 figs. Description of process and examples of welding.

Theories. Theories of Electric Welding. Practical Engr., vol. 66, no. 1845, July 6, 1922, pp. 5–6. Electrodes of future; carbon; brittleness; harmful elements.

ELECTRIC WELDING, ARC

Cyc-arc. The "Cyc-arc" Process of Automatic Electric Welding in Ship Work, L. J. Steele and H. Martin. Electrician, vol. 89, no. 2306, July 28, 1922, pp. 98–99, 3 figs. Recent developments. Success in making mild-steel welds.

Monel Metal. Arc Welding Monel Metal, P. D. Merica and J. G. Schoener. Welding Engr., vol. 7, no. 7, July 1922, pp. 42–44 and 46, 6 figs. Use of metallic deoxidizers has resulted in sound, strong, and moderately ductile welds. From paper read before Am. Welding Soc.

EMERY PAPER

Manufacture. Improving Emery Paper (Metod för förbättring av smärgelpapper), C. Benedicks and E. Sörberg. Jerkontorets Annaler, vol. 106, no. 5, 1922, pp. 178–185, 10 figs. Describes production under pressure and gives results obtained.

ENGINEERING SCHOOLS

Curricula, Criticism of. Engineering Schools Fall Short of Modern Needs, John H. Dunlap. Eng. News-Rec., vol. 89, no. 6, August 10, 1922, pp. 224–226. Criticisms of present methods; suggests longer course for engineering degree. Author is secretary of Am. Soc. Civil Engrs.

ENGINEHOUSES

Concrete-Unit. Concrete-Unit Roundhouses on the Pennsylvania R. R. Eng. News-Rec., vol. 89, no. 3, July 20, 1922, pp. 110–112, 3 figs. Large buildings framed of precast members; walls of brick and steel sash; casting yard and unit erection methods.

Southern Pacific. Southern Pacific Builds Unique Engine Houses. Ry. Age, vol. 73, no. 3, July 15, 1922, pp. 105–106, 2 figs. Rectangular concrete structures are provided with lead tracks at each end to expedite use.

EVAPORATION

Problems. The General Problem of Evaporation, J. W. Hinchley. Soc. Chem. Industry Jl., vol. 41, no. 14, July 31, 1922, pp. 242T–246T, 3 figs. Study

of evaporation below boiling point of liquid evaporated and evaporation at boiling point.

EXTRUSION OF METALS

Process. Extrusion of Metals (Quelques lois expérimentales de l'écrouissage), L. Poitrinal. Technique Moderne, vol. 14, no. 5, May 1922, pp. 193–199, 6 figs. Different ways of deformation; determination of parameters required; extrusion by compression, traction, and compression and traction simultaneously.

F

FACTORIES

Location. Industrial Plants and Their Location, F. Theo. Gnaedinger. Eng. Inst. Canada Jl., vol. 5, no. 7, July 1922, pp. 354–358, 4 figs. General survey of principal features to be considered in locating, designing and constructing industrial plant.

Protection Against Loss and Theft. Protecting Industrial Plants and Contents Against Loss and Theft, Joseph Mayhew. Management Eng., vol. 3, no. 2, Aug. 1922, pp. 109–110. Loss and theft from within industrial organization; responsibility of management; example of systematic leakage.

FANS

Tests. Fan Testing (Undersökelse av Ventilatorer), Johan Grönningsaeter. Teknisk Ukeblad, vol. 69, nos. 18, 19 and 21, May 5, 12 and 26, 1922, pp. 159–163, 170–174 and 195–198, 26 figs. May 5: Results of tests of fans carried out at Norwegian Technical High School during 1919. May 12: Tests with torpedo-boat fan equipment. May 26: Tests with Sirocco fans.

FATIGUE

Industrial. Fatigue in Industry (Le Problème de la fatigue dans l'Industrie), Jean Waldsburger. Vie Technique et Industrielle, vol. 3, nos. 31 and 32, Apr. and May 1922, pp. 25–27 and 95–97, 5 figs. Apr.: Research work of Prof. Kent, in England, on study of fatigue in men and women workers, and instruments used for measurements. May: Research work of J.-M. Laby, in France.

FEEDWATER HEATERS

Locomotive. Practical Advantages of Locomotive Feed Water Heating. Ry. Rev., vol. 70, no. 23, June 10, 1922, pp. 825–830, 6 figs. Maintenance and operation of locomotive feedwater heaters on 14 railroads. Int. Ry. Fuel Assn. report.

FIRE FIGHTING

Chemicals for. Chemicals Met with in Fire Fighting, Raymond Szymanowitz. Fire & Water Eng., vol. 71, no. 22, May 31, 1922, pp. 987–988 and 1006. Showing forms, qualities and reactions under influence of heat and water of all such substances; knowledge needed to intelligently handle chemical fires.

FIRE PREVENTION

Water Works Coöperation. How the Water Works Should Aid in Fire Fighting, Clarence Goldsmith. Fire & Water Eng., vol. 72, no. 1, July 5, 1922, pp. 7–8. Suggestions as to active coöperation between water and fire departments; water-works employees should answer alarms; hydrant inspection; matter of adequate pressure.

FIRECLAYS

Eastern Kentucky. Fire Clays of the Eastern Coalfield of Kentucky, H. Ries. Am. Ceramic Soc. Jl., vol. 5, no. 7, July 1922, pp. 397–408, 6 figs. Flint, semi-flint and plastic clay of real commercial value and geological analysis of occurrence.

FLIGHT

Soaring. An Explanation of Soaring Flight, J. W. Miller. Aviation, vol. 13, no. 5, July 31, 1922, pp. 121–123, 5 figs. Elementary theory. Condensed outline of series of lectures before Northwest Aeronautical Soc.

Soaring Flight and Its Mechanical Solution, F. W. Ruben. Aviation, vol. 12, no. 26, June 26, 1922, pp. 750–752, 5 figs. Observation of bird flight discloses ability of birds to vary their wing area with changing wind pressure.

FLOUR MILLS

Diesel-Engine Drive. The Dittlinger Mills, John Pierce. Power Plant Eng., vol. 26, no. 13, July 1, 1922, pp. 652–655, 5 figs. Description of Diesel-engine plant in flour mill at New Braunfels, Tex. Engine 225 hp.

FLOW OF WATER

Measurement. Methods and Apparatus for the Photometric Gaging of the Flow of Water (Procédés et appareillage pour le jaugeage photometrique de faibles cours d'eau), Paul P. E. Papadopoulo-Santo Rini. Annales de l'Energie, vol. 2, no. 3, May-June 1922, pp. 97–101, 11 figs. Describes method consisting of introduction of liquid color at one point and photometric determination of color on water at a given distance at a certain time.

The California Pipe Method of Water Measurement, Blake R. Vanleer. Eng. News-Rec., vol. 89, no. 5, Aug. 3, 1922, pp. 190–192, 3 figs. Description of apparatus used and its operation; tables and charts employed.

FLUE-GAS ANALYSIS

Apparatus for. A New Flue Gas Tester, Max Moeller. Eng. Progress, vol. 3, no. 7, July 1922, pp. 151–152, 3 figs. Instrument based on variation in heat conductivity of flue gases produced by alteration of CO_2 content by electrical means.

Automatic Carbon Dioxide Indicator for Flue Gas, R. B. MacMullin. Jl. Indus. & Eng. Chem., vol. 14, no. 7, July 1922, pp. 628–629, 2 figs. Description of instrument accurate to 0.02 per cent, which will record continuously for two days or more without need of refilling scrubber or readjusting zero point.

FLUE GASES

Movement. New Theory on the Movement of Flue Gases (Etude théorique nouvelle relative au mouvement spontané des gaz d'un courant de chauffage), H. Tripier. Chaleur et Industrie, vol. 3, nos. 25 and 26, May and June 1922, pp. 1244–1250, and 1360–1367, 10 figs. Discusses draft in stack, and losses connected with it, on basis of Bernoulli formula. Develops other formulas and methods of practical calculation, which are more general and more exact.

FORGINGS

Brass. Brass Forgings, C. G. Heiby. Metal Industry (Lond.), vol. 21, no. 2, July 14, 1922, pp. 25–27. Description of process; sand-cast blanks; chill-cast blanks; composition of metal; physical properties.

Hammers, Pneumatic. "Single-Blow" Pneumatic Forging Hammers, W. H. Snow. Engineering, vol. 114, no. 2952, July 28, 1922, pp. 98–101, 9 figs. Discussion of efficiency of operation, special reference to weight and duration of blow.

Steel for. Scientific Selection of Materials for Forgings. Am. Mach., vol. 57, no. 6, Aug. 10, 1922, pp. 211–215, 10 figs. Selection of steel; its testing and heat treatment.

FOUNDRIES

Compressed Air in. Compressed Air in the Foundry, L. W. Schnitzer. Compressed Air Mag., vol. 27, no. 7, July 1922, pp. 185–188, 8 figs. Pneumatic devices perform many useful operations in foundry; reduce costs and increase production.

Layout. Modern Tendencies in Foundry Installation (Tendances modernes présidant à l'Installation des Fonderies), M. Thomas. Fonderie Moderne, no. 5, May 1922, pp. 129–141, 4 figs. Foundries for heavy, medium, and mechanical castings; foundry sand; etc.

Malleable-Iron. Brass Firm Makes Malleables, Pat Dwyer. Foundry, vol. 50, no. 13, July 1, 1922, pp. 523–528, 10 figs. Powdered-coal equipment for annealing and core ovens; 100,000 sq. ft. of floor space and all modern improvements in sanitation, safety devices, dust exhaust system, etc.

Planning a New Malleable Shop, E. Tonceda. Iron Trade Rev., vol. 71, no. 4, July 27, 1922, pp. 243–248, 3 figs. Consideration governing site selection and plant layout; design of equipment. (Abstract.) Exchange paper before Instn. British Foundrymen.

Safety. Safety Work in Foundries, R. W. Patmore. Metal Industry (Lond.), vol. 20, no. 25, and vol. 21, no. 1, June 23 and July 7, 1922, pp. 584–585 and 3–4. Also Foundry Trade Journal, vol. 25, no. 305, June 22, 1922, pp. 464–467. Analysis of causes of major and minor accidents in foundry and suggestions for campaign to reduce practice of same. Presented at Inst. British Foundrymen.

FRAMES

Kinematic Theory of. Kinematic Theory of Framework (Théorie cinématique du treillis), Léon Legens. Génie Civil, vol. 81, no. 2, July 8, 1922, pp. 40–43, 18 figs. Develops formulas and makes calculations.

FUEL ECONOMY

Power Plants. Fuel Economy in Steam Power Plants, John B. C. Kershaw. Beama, vol. 11, no. 1, July 1922, pp. 474–481, 3 figs. Composition and constitution of natural and artificial fuels, and chemistry of combustion process.

Fuel Economy and Production Expenses, Allen M. Perry. Elec. World, vol. 80, no. 3, July 15, 1922, pp. 115–118. Data given for electric plants burning coal, oil, gas and hogged fuel; careful analysis of data permits interesting comparisons between results obtained.

FUELS

Garbage. Burning Garbage Under the Boiler (Die Verwertung von Mull durch Verbrennung), H. Hermann. Gesundheits-Ingenieur, vol. 45, nos. 21 and 26, May 27 and June 30, 1922, pp. 274–278 and 339–343, 12 figs. May 27: Furnaces fired with garbage and other refuse, especially for hot water and heating purposes. June 30: Garbage incinerating plants, their operation and equipment.

Sawdust. Sawdust as Fuel. Elec. Rev., vol. 89, no. 2282, Aug. 19, 1922, pp. 236–238, 8 figs. Details of plant installed by John Sadd & Sons, Ltd., Maldon, Essex, for production of gas from sawdust.

[See also COAL; COKE; OIL FUEL; PEAT; PULVERIZED COAL.]

FURNACES, HEAT-TREATING

Continuous. Continous Furnaces and Their Application, P. J. Myall and L. A. Mekler. Forging & Heat Treating, vol. 8, no. 7, July 1922, pp. 322–326, 5 figs. Classification of continuous furnaces; type of furnace recommended for various operations; writers believe there should be ten continuous furnaces for one now in operation.

Scale Formation. Furnace Atmospheres and Their Relation to the Formation of Scale, George C. McCormick. Am. Soc. for Steel Treating Trans., vol. 2, no. 11, Aug. 1922, pp. 1006–1012, 3 figs. Experimental data and procedure during investigation of scaling activity of oxidizing, neutral and reducing atmospheres during heat treatment of steel.

FURNACES, BOILER

Air Preheaters. Air Preheaters for Boiler Furnaces. Engineering, vol. 114, no. 2949, July 7, 1922, pp. 24–27, 10 figs. Description of apparatus built by Ljungström Steam Turbine Co.

FURNACES, METALLURGICAL

Aluminum-Melting. Aluminum and Aluminum-Alloy Melting Furnaces, Robt. J. Anderson. Can. Foundryman, vol. 13, no. 7, July 1922, pp. 19–23, 3 figs. Review of work undertaken by U. S. Bur. Mines to decrease metal and fuel losses in melting.

G

GALVANIZING

Weight of Coating. Determination of Spelter Coating on Sheets, D. M. Strickland. Raw Material, vol. 5, no. 6, July 1922, pp. 227–228, 1 fig. Simple and accurate method which may be applied to all shapes and sizes of specimens. Portable equipment for field tests. Paper read at annual mtg. Am. Soc. for Testing Mtls.

GAS ENGINES

Blast-Furnace Gas. The Nurnberg Gas Engine (Die Nürnberger Gasmaschine), J. Schmidt. Elektrotechnischer Anzeiger, vol. 39, nos. 72, 73 and 74, May 6, 9 and 10, 1922, pp. 601–602, 613–614 and 619–620, 5 figs. Describes 4-stroke, two-cylinder tandem engine, 700 hp. at 125 r.p.m. (normal size 2,000 hp.), for more economic utilization of blast-furnace gas; consumes 2200 to 2400 German heat units per b.hp-hr., at full load; application of tandem gas engines for driving dynamos.

GAS PRODUCERS

Ash-Fusion. Ash Fusion Gas Producer, M. A. Fichet. Am. Gas Jl., vol. 116, no. 24, June 17, 1922, pp. 550–552, 2 figs. Producer resembling small blast furnace in which complete combustion is attained by burning coal to fusion of ash. From Journal des Usines à Gaz., 1922, pp. 1–7.

Brick Manufacture. The Use of Producers and Their Gas in Burning Brick (Ueber die Verwendung von Generatoren und ihrer Gase zum Brennen von Ziegeln), Hubert Hermanns. Wärme, vol. 45, nos. 22 and 23, June 2 and 9, 1922, pp. 271–273 and 286–289, 17 figs. June 2: Compares gas- and direct-firing and describes various types of producers comparing their heat balance. June 9: Annular furnaces fired with producer gas; drying of wet lignite gas.

Electric. Gasification of Fuels by Means of the Electric Current (Vergasung von Brennstoffen mit Hilfe des elektrischen Stromes), Gwosdz. Wärme, vol. 45, no. 20, May 19, 1922, pp. 247–250, 1 fig. Application of electric curent to gas producers; describes Stassano, Girod, Holengren, and other types of apparatus.

GASES

Hydraulic Compression. Production of Pure Gases by the Principle of Hydraulic Compression (Gewinnung reiner Gase unter Anwendung des hydraulischen Kompressionprinzips), C. Heirich. Zeit. für komprimierte u. flüssige Gase, vol. 22, nos. 1, 2 and 3, 1922, pp. 3–7, 21–22 and 43–44, 1 fig. Principles and operation of hydrocompressor; gives cost data of a plant; use of hydraulic compressors in Linde liquefaction and rectification process for production of liquid or gaseous oxygen.

GASOLINE METERS

Grandberg. An Accurate Gasoline Meter, A. J. Dickie. West. Machy. World, vol. 13, no. 6, June 1922, pp. 189–191, 204, 8 figs. Description of measuring device invented by Grandberg and which requires tooling for manufacture on quantitative production basis.

GEAR CUTTING

Bevel. Cutting Bevel Gears, Franklin D. Jones. Machy. (N. Y.), vol. 28, no. 12, Aug. 1922, pp. 968–971, 7 figs. Principal adjustments required in setting up Gleason bevel-gear generators and time required for cutting gears of different sizes and pitches.

High-Speed. Producing Gears in Quantity at High Speed, J. H. Rodgers. Can. Machy., vol. 28, no. 1, July 6, 1922, pp. 33–35, 4 figs. Modern gear cutters very efficient; multiple fixtures reduce non-productive time; automatic operation practically eliminates possiblity of error, special method for bevel gears.

GEARS

Gear-Tooth Comparator. A New Instrument for Checking Gear Tooth Profiles and Spacing. Automotive Industries, vol. 47, no. 4, July 27, 1922, p. 171, 3 figs. Describes odontometer for comparing uniformity or determining interchangeability of gears. Applicable to gears of any pressure angle; can be applied while gear is still in machine.

GIRDERS

Calculation. Calculation of Girders on Two Supports Partly Fixed (Calcul général des pièces à deux appuis à encastrement partiel), Louis Gellusseau. Génie Civil, vol. 80, nos. 14, 15, 16, 17, 18, 24 and 25, Apr. 8, 15, 22, 29, May 6, June 17 and 24, 1922, pp. 315–318, 335–339, 359–361, 375–378, 401–403, 546–548, and 564–567, 32 figs. Discusses reinforced-

concrete construction, detailed definition of "encastrement," develops formulas and makes calculations for string boards, rectangular frames, circular and parabolic arches, girders with constant and variable cross-sections, etc.

GLASS MANUFACTURE

Factories. The Modern Glass Factory, W. S. Mayers. Glass Industry, vol. 3, no. 7, July 1922, pp. 129-134, 3 figs. Location with consideration to power and water, buildings, auxiliary equipment, air ducts, railroad sidings, and various other features.

Movement in Pots and Tanks. Movement of Molten Glass in Pot Furnaces and Tanks, Henry W. Hess. Glass Worker, vol. 41, no. 40, July 1, 1922, p. 11. Changes of temperature affect movement of refined glass. Careful regulation of furnace conditions will eliminate most troubles. Production of cords and waves in pots.

Optical Glass. Manufacture of Optical Glass (Fabrication des Verres d'Optique), Paul Nicolardot. Nature, no. 2515, July 8, 1922, pp. 17-23, 9 figs. Prime materials used, refractories and furnaces, molding, annealing, coloring, etc.

The Manufacture of Optical Glass (Ueber die Herstellung von optischem Glas). Sprechsaal, vol. 55, nos. 17, 18, 19 and 20, Apr. 27, May 4, 11 and 18, 1922, pp. 195-198, 209-211, 221-222, and 233-235, 13 figs. Apr. 27: Methods developed in England during war. May 4: Coloring and testing, optical constants, scientific side of glass manufacture. May 11: Relation between composition of glass and refractory index. May 18: Relation between composition and durability, molecular composition and solubility.

Presses, Automatic. Balanced Toggle Aids in Getting Proper Degree of Pressure. Glass Worker, vol. 41, no. 43, July 22, 1922, pp. 11 and 29-30, 3 figs. Mechanism for pressing glassware by balanced toggle produces proper weight pressure at all times.

GRINDING

Bearings. Grinding in the Automotive Industry. Machy. (N. Y.), vol. 28, no. 12, Aug. 1922, pp. 946-951, 11 figs. Methods of grinding steel balls and ball-bearing races, grinding roller bearing cups, cones and rollers.

H

HANGARS

Cable-Suspended Roof. Cable-Suspended Roofs for Hangars, Workshops, Docks, Etc. (Toitures supportées par des fermes de suspension isostatiques en cables pour hangars, ateliers, docks, etc.), G. Leinekugel le Cocq. Bul. de la Societe d'Encouragement pour l'Industrie Nationale, vol. 134, no. 5, May 1922, pp. 396-417, 15 figs. Describes construction of Cherbourg and other hangars with very wide span in which roof is suspended from cables at either end.

HARDNESS

Testing. Hardness Testing Methods (Sur les Methodes d'essai de dureté des corps), Georges Moreau. Révue Générale de l'Électricité, vol. 12, no. 3, July 22, 1922, pp. 106-111, 3 figs. Describes new method of testing materials, being improvement on Brinell method, i.e., dynamic hardness which is defined as relation between pressure exerted by ball during penetration on surface of impression.

The Testing of Metals for Hardness, S. P. Rockwell. Am. Soc. for Steel Treating Trans., vol. 2, no. 11, Aug. 1922, pp. 1013-1033, 27 figs. Results of tests made on standard Brinell, scleroscope and Rockwell hardness-testing machines.

HEAT STORAGE

Apparatus. Heat Storage Apparatus, C. Boileau. Elec. Times, vol. 62, no. 1603, July 6, 1922, pp. 7-9. Raising of central-station load factors by electric heat storage. From L'Électricien.

HEAT TRANSMISSION

Non-Conducting Materials. The Transmission of Heat Through and the Efficiency of Non-Conducting Materials, Masao Kinoshita. Domestic Eng. (English), vol. 42, no. 42, June 1922, pp. 116-120, 5 figs. Mathematical consideration (1) in which distribution of temperature in system of bodies considered remains unchanged, and (2) in which temperature distribution changes from time to time.

Refractory Materials. The Thermal Conductivity of Refractory Materials at High Temperatures, A. T. Green. Gas World, vol. 77, no. 1905, July 1, 1922, pp. 13-14, 2 figs. Review of previous work; Fourier's linear-diffusion equation, measurement of rate of rise of temperature for isothermal plane at known distance from hot face, texture; porosity; results. Paper read before Instn. Gas Engrs.

HYDRAULIC TURBINES

Queenston-Chippawa Plant. 55,000-Hp. Turbines for the Queenston Power Station, Ontario. Engineering, vol. 114, no. 2950, July 14, 1922, pp. 31-35, 19 figs. Description of turbines of Queenston-Chippawa development with illustration.

HYDROELECTRIC DEVELOPMENTS

Canadian Progress. Hydro-Electric Progress in Canada. Universal Engr., vol. 35, no. 6, June 1922, pp. 24-27. Brief review of development work in individual provinces and of progress in investigation and plans.

Germany. South German Electric Economics (Die Süddeutsche Elektrizitätswirtschaft), H. Putz. Elektrotechnische Zeit., vol. 43, no. 27, July 17, 1922, pp. 901-904, 1 fig. Water-power resources of Bavaria, Baden and Württemberg, the question of equal distribution; consumption of energy, 110 kv transmission line.

India. The Hydro-Electric Survey of India, J. W. Meares. Beama, vol. 10, no. 6, June 1922, pp. 409-411. 350,000 hp. developed or under construction, 1½ million hp. investigated by Survey, 1½ million in known sites not yet investigated, probably 4 to 10 million more.

The Power Factor—India's Natural Resources. Indian Industries & Power, vol. 19, no. 9, May 1922, pp. 302-307, 3 figs. General consideration of value of power development to Indian industry. Table of investigated prospects.

Queenston-Chippawa, Canada. Queenston-Chippawa Developments of the Hydro-Electric Power Commission of Ontario, F. A. Gaby. Am. Inst. Elec. Engrs. Jl., vol. 41, no. 7, July 1922, pp. 508-526, 29 figs. General description of entire development on Canadian side of Niagara River which will have ultimate capacity of approximately 650,000 hp.

Tugalo River. Water Power Development on the Tugalo River. Eng. World, vol. 21, no. 1, July 1922, pp. 7-8, 5 figs. Georgia Ry. & Power Co. 50,000-Kw. development costing $1,600,000 to be finished next year.

HYDROELECTRIC PLANTS

France. Hydroelectric Plant at Mouthier (L'usine genératrice hydroélectrique de la Loue, à Mouthier), J. Reyval. Révue Générale de l'Électricité, vol. 11, no. 19, May 13, 1922, pp. 691-714, 21 figs. Describes generating station at Mouthier on the Loue; total power 16,000 hp.; generating equipment; overhead lines; transformers; stations, etc.

Hydroelectric Plant of the Paul Girod Steel Works at Ugines, Savoie [Les Usines hydro-électriques de la Compagnie des Forges et Aciéries électriques Paul Girod a Ugines (Savoie)], V. Sylvestre. Houille Blanche, vol. 21, no. 65-66, May-June 1922, pp. 73-83, 10 figs. Describes civil-engineering work in connection with construction of dams and reservoirs; pressure piping; Pelton wheels; etc.

Germany. Concrete and Reinforced-Concrete Works at the Isar (Beton- und Eisenbetonarbeiten an der Mittleren Isar), Hans Stanglmayr. Bauingenieur, vol. 3, no. 11, June 15, 1922, pp. 334-342, 9 figs. Reviews number of hydroelectric power works on this river in vicinity of Munich, and gives details of construction work.

New Hydroelectric Plants in Bavaria and Thuringia (Neuere Wasserkraftanlagen in Bayern und Thüringen), Schwenk. Bauingenieur, vol. 3, nos. 8, 9, 10 and 11, Apr. 30, May 15, 31 and June 15, 1922, pp. 230-234, 267-273, 300-307 and 330-334, 40 figs. Apr. 30: Civil engineering features of Wisenttal power plant and electric equipment, including Francis double-spiral turbines by Escher, Wyss & Co., and d.c. generators by Siemens-Schuckert. May 15: Describes power plant at Ziegenruck, on river Saale, its constructional features and equipment. May 31: Describes power plant at Hausen; hydraulic features, turbine equipment, etc. June 15: Describes power plant No. 2 at Munich, South, and its equipment, including two units of two coupled Francis turbines each, having head of 4.4 m., 1760 hp. at 125 r.p.m., and 80 per cent efficiency.

Italy. Hydroelectric Plant of the Barbellino (L'impianto idroelettrico del Barbellino), F. Zanon. Industria, vol. 36, no. 11, June 15, 1922, pp. 201-208, 9 figs. Hydraulic construction work; dams and reservoirs of the lakes of Barbellino, Malgina and Valmorta; power piping; list of central stations drawing their water power from these lakes.

Sweden. Haugesund Electric Power Station (Haugesundhalvöens og Karmöys elektrisitetsforsyningsanlaeg), O. Aas-Jörgensen. Teknisk Ukeblad, vol. 69, no. 27, July 7, 1922, pp. 252-255, 9 figs. Construction work and equipment of this high-tension station with 60,000 volts capacity.

Switzerland. An Extra-High Head Hydro-Electric Plant. Engineer, vol. 134, no. 3474, July 28, 1922, pp. 88-90, 9 figs. Description of Fully plant in Switzerland, operating under head of 1650.7 m., or 5416 ft.

I

ICE MANUFACTURE

Clear Ice. Making of Clear Ice, John E. Starr. Refrig. World, vol. 57, no. 7, July 1922, pp. 11-12 and 14. Increase to ice-making capacity and cold-storage space obtained by remodelling and modernizing plant and equipment.

Development. Development in the Manufacture of Ice, Harry T. Whyte. Nat. Engr., vol. 26, no. 7, July 1922, pp. 290-293, 13 figs. Review of progress of industry; advantages and disadvantages of present types; economics of plant operation.

ICE PLANTS

Refrigerator Cars, for. Car Icing Station for the Belt Railway of Chicago. Eng. News-Rec., vol. 89, no. 6, Aug. 10, 1922, pp. 240-242, 4 figs. Refrigerator cars at transfer yard supplied with cake or crushed ice; conveyors, carts and portable chutes.

IGNITION

Angle of Cylinder Axes. Angle of Cylinder Axes for Uniform Ignition (Gabelwinkel für gleichmässige Zündfolge bei mehrreihigen Verkehrsmotoren), H. Schrön. Motorwagen, vol. 25, nos. 16 and 17, June 10 and 20, 1922, pp. 307-312 and 329-333, 107 figs. Describes angle of cylinder axes in connection with crankshaft arrangements for multiple cylinder motors. Concludes that construction with cylinders opposite each other leaves free choice of angle but complicates crankshaft, normal construction simplifies crankshaft.

High-Tension Spark. High-Tension Spark Ignition in Internal-Combustion Engines, J. D. Morgan. Instn. Mech. Engrs. Proc., no. 2, 1922, pp. 303-315, 6 figs. What is expected of spark generators and discussion of spark and conditions affecting its production.

IMPACT TESTING

Alloy Steels. Significance of the Impact Test, F. C. Langenberg and N. Richardson. Forging & Heat Treating, vol. 8, no. 7, July 1922, pp. 309-312. Typical test data on certain alloy steels and ordnance steels are recorded, illustrating author's conclusions and furnishing opportunity for comparison of static and dynamic tests. Paper from Symposium before Am. Soc. for Testing Matls.

INDUSTRIAL MANAGEMENT

Ford's Four Production Principles. Ford's Four Production Principles, Samuel Crowther. Factory, vol. 29, no. 1, July 1922, pp. 15-17. Never letting well enough alone; always apportioning responsibility definitely; holding foremen not for costs but for production; treating interest charges as decreased profit.

Forge Shops, Records. Miscellaneous Records, Statistics and Suggestions for Drop Forgers, Geo. H. Koskey. Forging & Heat Treating, vol. 8, no. 7, July 1922, pp. 317-320. Suggesting sliding scale upward, where production depends on human elements; in this case firm would make profit on more pieces, reduce cost and benefit worker.

Malleable Shop System. System Rules Malleable Shop, H. E. Diller. Foundry, vol. 50, no. 13, July 1, 1922, pp. 537-541, 8 figs. Records of progress of work in large foundry are kept on simplified forms; four men handle routine for more than 200 molders; how work is scheduled.

Stabilizing Profits by Charts. Charting as an Aid in Stabilizing Profits, Percy A. Bivins. Indus. Management, vol. 63, nos. 5 and 6, and vol. 64, no. 1, May, June and July 1922, pp. 257-265, 355-361 and 33-42, 29 figs. Enabling executives to apply graphic methods to problem of profit stabilization.

INSPECTION

See OPTICAL INSTRUMENTS.

INSTRUMENTS

Scientific, Mechanical Design. The Mechanical Design of Scientific Instruments. Engineering, vol. 113, nos. 2945, 2946, 2947 and 2948, June 9, 16, 23 and 30, 1922, pp. 729-730, 763-764, 794, and 828-829, 24 figs. Consideration in design of qualitative and quantitative instruments used in many branches of physical, engineering and chemical sciences. Abstract of three Cantor Lectures delivered before Royal Soc. of Arts.

INTERNAL-COMBUSTION ENGINES

Marine, Still System. Still System of Internal Combustion Engine for Marine Purposes, F. L. Martineau. Inst. Mar. Engrs. Trans., vol. 34, Apr. 1922, pp. 37-47, and (discussion) 47-58, 2 figs. Discussion of Still system; any internal-combustion engine can operate on it by certain modifications and improve its results 20 per cent.

Maximum Pressures. Comparing Maximum Pressures in Internal Combustion Engines, Stanwood W. Sparrow and Stephen M. Lee. Nat. Advisory Committee for Aeronautics Tech. Notes no. 101, June 1922, 4 pp., 3 figs. Thin metal diaphragms form satisfactory means; diaphragm is clamped between two washers in spark-plug shell and its thickness is chosen such that when subjected to explosion pressure exposed portion will be sheared from rim in short time.

Price Horizontal Engine. The Price Horizontal Engine. Power Plant Eng., vol. 26, no. 14, July 15, 1922, pp. 707-708, 4 figs. Combustion at constant volume, solid injection of fuel in two sprays.

Sulzer Two-Cycle. Four Cylinder Two-Cycle Sulzer Engine. Mar. Eng. vol. 27, no. 7, July 1922, pp. 443-444, 1 fig. Designed to develop 2,000 b.hp. at 100 r.p.m.; turbo scavenging pumps used.

Sulzer 2-Cycle Marine Engine, L. J. LeMesurier. Inst. Mar. Engrs. Trans., vol. 33, Mar. 1922, pp. 723-776 and (discussion) 776-790, 45 figs. Discussion of relative merits of 4- and 2-cycle internal-combustion engines and reasons for adoption of 2-cycle for larger powers by Sulzers.

[See also AIRPLANE ENGINES; AUTOMOBILE ENGINES; DIESEL ENGINES; GAS ENGINES; IGNITION; OIL ENGINES; SEMI-DIESEL ENGINES.]

IRON

Puddled. Make Puddled Iron Mechanically, E. C. Kreutzberg. Iron Trade Rev., vol. 71, no. 6, Aug. 10, 1922, pp. 365-366, 9 figs. Description of puddler developed at Eastern plant producing 1500-lb. puddle balls at rate of one per hr.

IRON AND STEEL

Fiber in. Fiber in Iron and Steel, F. F. McIntosh. Am. Soc. for Steel Treating, Trans., vol. 2, no. 10, July 1922, pp. 856-863 and (discussion) 864-868, 9 figs. Importance of fiber in performance of iron or steel and factors which govern formation and character.

IRON CASTINGS

Manufacture Direct from Ore. Making High-Grade Castings Direct from the Ore, F. H. Bell. Can. Foundryman, vol. 13, no. 7, July 1922, pp. 17–18, 2 figs. Ore melted in ordinary blast furnace is kept in vacuum thermos container until chemical analysis is taken, after which it is mixed with cupola iron.

Rolls. Casting Rolls (Walzenguss), Carl Irresberger. Giesserei Zeitung, vol. 19, nos. 23, 24, 25 and 26, June 6, 13, 20 and 27, 1922, pp. 342–345, 354–358, 371–374 and 381–386, 55 figs. Processes of casting steel rolls, tempered and untempered cast-iron rolls; molds, annealing furnaces; hardening and depth of penetration; hollow rolls.

Typewriter Frames. Making Typewriter Frames in a Belgium Foundry, Joseph Leonard. Can. Foundryman, vol. 13, no. 6, June 1922, pp. 32–33, 8 figs. Method of molding and casting. Comparatively simple rigging designed to produce 35 to 40 frames per day.

J

JAPANNING

Methods. Japanning, S. R. Gerber. Metal Industry (N. Y.), vol. 20, nos. 6 and 7, June and July 1922, pp. 225–227 and 161–163, 5 figs. Description of methods by which rule-of-thumb operations of an old art were changed to standard operations.

K

KEROSENE

Vegetable and Animal Oils as Sources. Catalytic Transformation of Vegetable and Animal Oils Into Kerosene (Transformation catalytique des huiles végétales et animales en pétrole), Alphonse Mailhe. Annales de Chimie, vol. 17, May-June 1922, pp. 304–332. Concludes that it is easy to reduce hydrocarbons from animal and vegetable oils, and that resulting hydrocarbons are in nature of mixed kerosenes very much like Borneo kerosene which has similar composition.

L

LABOR

Craftsmen Councils. Brief History of Craftsmen Movement in Cleveland. Universal Engr., vol. 36, no. 2, Aug. 1922, pp. 42, 44 and 46, 1 fig. Organization of craftsmen councils by groups of masons engaged in same line of industry.

India. Inefficiency Offsets India's Cheap Labor, James Allen DeForce. Iron Trade Rev., vol. 71, no. 6, Aug. 10, 1922, pp. 368–369. General data with some information on labor regulation.

LABORATORIES

Electrotechnical. Technical Laboratories of the Postal Telegraph Office (Le laboratoire technique des postes et télégraphes), Jacques Boyer. Nature, no. 2512, May 27, 1922, pp. 325–330, 8 figs. Describes Paris official laboratory in which telegraph, telephone and other instruments of the service are tested.

Testing, Electric. A 500,000-Volt Testing Laboratory (Un laboratoire d'essais à 500,000 volts), H. de Raemy. Révue Générale de l'Électricité, vol. 11, no. 23, June 10, 1922, pp. 861–864, 6 figs. Describes new laboratory of Ateliers de Constructions électriques de Delle, at Villeurbanne, which is especially designed for testing of high-tension apparatus for transmission lines.

LADLES

Stopper. Development in Design of Casting Ladle Bungs. Metal Industry (Lond.), vol. 20, no. 26, June 30, 1922, pp. 621–622, 6 figs. Discussion of design which should make connection between bung rod and bung absolutely certain and easy to effect. From Stahl u. Eisen.

LIGHTING

Glareless. Light Without Glare, Ward Harrison. Am. Inst. Elec. Engrs. Jl., vol. 41, no. 8, Aug. 1922, pp. 609–615, 8 figs. Discussion of features determining satisfactory illumination without glare. Includes tables from Illuminating Eng. Soc. Code of Indus. Lighting in which for first time light sources are modified.

Industrial. Good Lighting an Essential in the Efficient Conduct of Business, J. H. O'Hara. Elec. News, vol. 31, no. 13, July 1, 1922, pp. 36–39. Expenditure of one-half of one per cent of pay roll increases output five per cent. Saving equal to ten times expense. Practical example. Paper read before C.E.A. convention.

Rational Lighting (Considerations sur l'éclairage rationnel), R. Wolff. Électricien, vol. 37, no. 1290, Dec. 15, 1921 and vol. 38, nos. 1297, 1298 and 1299, Apr. 1, 15 and May 1, 1922, pp. 553–561, 145–151, 174–177 and 193–197, 38 figs. Dec. 15: Photometry; intensity; measurement of light. Apr. 1: Lighting of business establishments; direct and indirect lighting, reflective power of various paints; etc. Apr. 15: Describes reflectors of various types and their curves of luminosity. May 1: Extent to which light is used in various systems of direct, indirect, etc., lighting.

The Problems of Electric Lighting (Die Aufgaben der elektrischen Beleuchtung), H. Lux. Elektrotechnische Zeit., special no., May 28, 1922, pp. 32–40, 19 figs. The various types of direct and indirect lighting and description of apparatus.

Lecture and Drafting Rooms. Illumination of Lecture and Drawing Halls (Die Beleuchtung von Hör- und Zeichensalen), W. Wedding. Zeit. für Beleuchtungswesen, vol. 28, no. 11–12, June 15–30, 1922, pp. 73–76, 15 figs. Results of examination of number of halls. Finds that most of the arc lights have been replaced by half-watt lamps. Tabular statement of illumination data of halls inspected.

Office Buildings. Indirect Lighting in City Office Building, G. F. Evans & J. W. Morrison. Elec. World, vol. 80, no. 2, July 8, 1922, pp. 61–62, 6 figs. Dixie terminal building in Cincinnati uses system with 8 to 15 foot-candles; arcade illumination eliminates hanging fixtures; aids to maintenance included in design.

Safety. Illumination and the Worker, G. Bertram Regar. Safety, vol. 9, no. 7, July 1922, pp. 156–160, 4 figs. Value of correct use in making for safe conditions in industry.

LIGNITE

Carbonization. Modern Methods of Treating Lignite and Its Derivatives (Procédés modernes pour le traitement du lignite et de ses derives). Chaleur et Industrie, vol. 3, no. 25, May 1922, pp. 1274–1276, 2 figs. Discusses carbonization; Fischer rotary furnace.

Degasification. Comparative Experiments on Degasification of Lignite on a Technical and Laboratory Scale (Vergleichende Versuche uber Entgasung von Braunkohle im technischen und Laboratoriums-Massstabe), K. Bunte and Fritz Schwarzkopf. Gas- u. Wasserfach, vol. 65, nos. 21, 22 and 23, May 27, June 3 and 10, 1922, pp. 322–325, 340–343 and 355–357, 15 figs. Experiments carried out with dirty Luckenau lignite for purpose of obtaining better results as to behavior of material than can be obtained from elementary analysis and coking sampling. Methods used were those of Gruppel, Strache, and muffle furnace.

LIME

Plants. New Lime Plant is Last Word in Modern Efficiency, William B. Eastwood. Cement, Mill & Quarry, vol. 21, no. 2, July 20, 1922, pp. 35–41 and 44, 14 figs. Mining, crushing, screening, calcining, hydrating and shipping are continuous without waste or climatic interruption.

LIQUIDS

Inflammable, Storage of. Storing Inflammable Liquids (Lagerung feuergefährlicher Flüssigkeiten). Zeit. des Bayerischen Revisions-Vereins, vol. 26, no. 12, June 30, 1922, pp. 100–102, 1 fig. Bavarian safety regulations for storage of petroleum, benzene, gasoline, etc., especially use of protective gas.

LOCOMOTIVE BOILERS

Circulation Effect on Efficiency. Effect of Circulation on Locomotive Boiler Efficiency, F. G. Lister. Steam, vol. 30, no. 1, July 1922, pp. 7–10. Recent attempts to create more rapid and unrestricted circulation thereby attaining more nearly uniform temperature throughout and reducing equal expansion and contraction of all parts. Paper read before Int. Ry. Fuel Assn.

LOCOMOTIVES

Combat. The Design of Combat Locomotives, R. S. Twogood. Jl. Pacific Ry. Club Proc., vol. 6, no. 3, June 1922, pp. 9–12. Notes on design deduced from experiences with those sent to France during recent war.

Design and Construction. Report on Locomotive Construction. Ry. Age (Daily), vol. 72, no. 24d, June 21, 1922, pp. 1631–1639. Various developments of year and résumé of 11 reports including recommendations (A.R.A. Mech. Div. Proc.).

Drifting Valves. When a Locomotive Drifts. Ry. Jl., vol. 28, no. 8, Aug. 1922, pp. 21–22, 3 figs., Description of Ripken automatic drifting valve.

Electric. See ELECTRIC LOCOMOTIVES.

Failure Causes and Remedies. Why Engines Fail, Frank C. Packard. Central Ry. Club Proc., vol. 30, no. 3, May 1922, pp. 1187–1198 and (discussion) 1198–1217. Analysis of failure and causes; losses caused thereby and argument for placing of full responsibility.

Fuel Consumption. Effect of Tonnage and Speed on Fuel Consumption, J. E. Davenport. Ry. Age, vol. 73, no. 2, July 8, 1922, pp. 71–75, 8 figs. Ton miles per hr. affects fuel rate; economical tonnage for various speeds, effect of grade and car weight. (Abstract.) Paper read before Int. Ry. Fuel Assn.

Increasing Mileage of. Increasing Locomotive Mileage—A Chemical Problem First, W. H. Hobbs. Ry. Rev., vol. 71, no. 1, July 1, 1922, pp. 11–12. Why better boiler feedwater is essential to increase in productive time of locomotives.

Mikado. New and Interesting Mikado Type Locomotive Built at the Lima Locomotive Works for the Michigan Central. Ry. & Locomotive Eng., vol. 35, no. 8, Aug. 1922, pp. 199–201, 4 figs. Specifications: Total length, 82 ft.; cylinder 28 in. by 30 in.; weight exclusive of tender, 334,000 lb.; weight of tender, 199,700 lb. with capacity of 16 tons fuel and 10,000 gal. water; driving wheel diam., 63 in.

Mountain Type. A Mountain Type Locomotive for High Capacity. Ry. Mech. Engr., vol. 96, no. 7, July 1922, pp. 381–385, 11 figs. New Union Pacific locomotive is lightest per unit of power of any 4-8-2 yet built, weighing 345,000 lb. and having maximum tractive effort of 54,800 lb. See also Ry. Rev., vol. 70, no. 23, June 10, 1922, pp. 815–825, 16 figs. partly on supp. plate.

Oil-Burning. Oil Fuel for Locomotives on the Taltal Railway of Chile, W. H. Revill. Ry. Gaz., vol. 36, no. 26, June 30, 1922, pp. 1030–1034, 6 figs. Comparison of oil and coal as fuel; economies which have been effected by use of oil; design of oil-fuel apparatus burners.

Operation. Work of the Commission for the Utilization of Fuel—6th Report (Travaux de la Commission d'Utilisation du Combustible—Sixième Rapport). Bul. de la Société d'Encouragement pour l'Industrie Nationale, vol. 134, no. 6, June 1922, pp. 565–599. Report of First Sub-Committee. Efficiency of locomotives; steam consumption and distribution; feedwater preheating; operation of locomotives.

Steam-Turbine. The Ljungström Turbine Locomotive (Ljungströms turbinlokomotiv), Fredrik Ljungström. Teknisk Tidskrift, vol. 52, nos. 21, 22, 23, and 25, May 27, June 3, 10 and 23, 1922, pp. 331–333, 348–351, 363–367 and 396–400, 31 figs. Experimental work, and construction and operation of locomotives driven by steam turbines. Particulars of saving resulting.

Turbo-Condensing. Turbo-Condensing Locomotive Development in Europe. Ry. Rev., vol. 71, no. 7, Aug. 12, 1922, pp. 201–207, 9 figs. Details of Ljungström turbine-condensing locomotive placed in service on Swedish State Railways.

LUBRICATING OILS

Analysis. Technical Examination of Lubricating Oil and Grease, F. W. Watson and H. D. Bell. Chem., Met. & Min. Soc. of So. Africa Jl., vol. 22, no. 11, pp. 211–219. Analytical methods and data. Results of tests.

Coolers for. Tubular Oil Cooler. Engineering, vol. 114, no. 2951, July 21, 1922, p. 89, 6 figs. Describes marine cooler having 250 sq. ft. cooling space, and which will deal with 1½ million B.t.u. per hr. Constructed by Serck Radiators, Ltd.

LUBRICATION

Mechanism of. The Mechanism of Lubrication, Robt. E. Wilson and D. P. Barnard, 4th. Soc. Automotive Engrs. Jl., vol. 11, no. 1, July 1922, pp. 49–60, 11 figs. Presenting best available data to afford basis for predicting effect of different variables under any specified conditions.

Oil Drops. What Determines the Size of the Oil Drop, W. F. Osborne. Power, vol. 56, no. 7, Aug. 15, 1922, pp. 251–252. Discussion of conditions affecting size of oil drops going to engine cylinder.

M

MACHINE TOOLS

Gear Drive. Methods of Machine Tool Design, A. L. De Leeuw. Am. Mach., vol. 57, no. 6, Aug. 10, 1922, pp. 223–227, 12 figs. Comparative merits of cone and tumbler quick gear-change device.

MACHINING

Deformation During. Avoiding Deformation During Machining, A. Whitehead. Engineer, vol. 134, no. 3474, July 28, 1922, pp. 98–99, 3 figs. Discusses as example, chucking of a ball race, machining small piston, and holding small armature.

MAGNESIUM ALLOYS

Engineering Uses. Magnesium Alloys in Engineering. Practical Engr., vol. 65, no. 1844, June 29, 1922, pp. 404–405, 2 figs. Electron (containing 80 per cent magnesium) for automobile pistons; general physical characteristics and precautions in molding.

MALLEABLE IRON

Drilling Data. Malleable-Iron Drilling Data, H. A. Schwartz and W. W. Flagle. Soc. Automotive Engrs. Jl., vol. 11, no. 1, July 1922, pp. 81–87, 12 figs. Drill tests of five factors that influence machining properties of malleable iron.

MARINE STEAM TURBINES

Low-Pressure Capacity. Capacities of Low-Pressure Marine Steam Turbines, W. G. P. Mech. World, vol. 71, no. 1852, June 30, 1922, pp. 466–467, 2 figs. Low- and high-steam velocity considerations in respect to turbine design and weight; mathematical development.

MATERIALS

Testing. Testing Materials for Shipbuilding, Leon Guillet. Engineering, vol. 114, no. 2950, July 14, 1922, pp. 57–58, 6 figs. Methods of testing. Tensile, falling weight, ball hardness, punching, wearing, alternating, and physical tests, and macrographic investigations.

MEASURING INSTRUMENTS

End Measurement. Accurate End Measurement on Measuring Machines Using a Screw, H. Baker. Engineer, vol. 134, no. 3474, July 28, 1922, pp. 81–83, 6 figs. Experiments relating to attempts to measure correctly to one ten-thousandth of a millimeter. Description of machine used and methods.

Hollow Membrane. Measuring and Regulating by Means of a Hollow Membrane (Messen und Regeln mit Hilfe der Hohlmembran), E. Stach. Glückauf, vol. 58, no. 26, July 1, 1922, pp. 807–813, 10 figs. Requirements of measuring and recording instruments as to construction and sensitiveness; shows that hollow metal membrane recorder gives better results than wet measuring instruments.

METAL SPRAYING

Metals for. Metals and Alloys Suitable for Spraying (Für Spritzguss geeignete Metalle und Legierungen), F. Reinboth. Metall-Technik, vol 48, no. 24, June 8, 1922, pp. 266-267. Gives composition of various alloys and rules for their choice for a given purpose which requires given physical or electrical properties.

Schoop Process. The Schoop Metal Spraying Process With Special Reference to Its Application to Shipbuilding (Das Schoopsche Metallspritzverfahren), M. U. Schoop. Schiffbau, vol 23, no. 38, June 21, 1922, pp. 1106-1107, 1 fig. Describes various uses of metallizing pistol for covering chains, anchors, etc., with zinc, ship bottoms and propellers with copper, etc.

METALS

Electroanalysis of Alloys and. Electroanalysis of Metals and Alloys, Kling and Lassieur. Chem. Trade Jl. and Chem. Engr, vol 71, no. 1835, July 21, 1922, pp. 73-74. Description of new rapid method of electrolytic analysis applicable to wide range of metals. Translated from Annales de Chimie Analytique, June 15, 1922.

Hardening. On the Theory of the Hardening of Metals, Kotaro Honda. Science Reports Tôhoku Imperial Univ. 1st series, vol 11, no 1, Apr 1922, pp. 19-28. Martensite being homogeneous solid solution, is hard principally because of nature of atomic forces; consideration of hardness due to crystalline structure of metals.

Spinning. Metal Spinning and Spinning Tools, Edward Heller. Machy (N. Y.), vol 28, no. 12, Aug 1922, pp. 972-976, 9 figs. Description of machinery and methods for various types of spinning.

MILLING MACHINES

Aligning and Inspecting. Aligning and Inspecting Milling Machines. Machy (Lond.), vol 20, no. 311, July 13, 1922, pp. 441-444, 6 figs. Methods employed by manufacturers of Cleveland milling machine.

MOLDING MACHINES

Types. Molding Machines (La staffatura a scosse ed alcuni tipi di staffatrici), P. A. Sordelli. Industria, vol. 36, no. 11, June 15, 1922, pp. 211-214, 9 figs. Describes various types of molding machines with pneumatic stripping arrangement, including that of Britannia Foundry, Coventry, and that of Leber & Brose, and their operation.

MONEL METAL

Tubular Uses. Monel Metal's Merits in Tubular Uses, J. L. Sussman. Raw Material, vol. 5, no. 6, July 1922, pp. 208-210, 6 figs. Manufacture in tube form is step toward solving problem of chemically resistant, non-fragile material.

MORTARS

Lime. Hardening of Hydraulic Binders—Quality and Acceptance of Lime (Le durissement des liants hydrauliques. Qualités et réception des chaux), E. Camerman. Annales de l'Association des Ingénieurs Sortis des Écoles Spéciales de Gand, vol. 12, no. 1, 1922, pp. 1-13, 1 fig. Discusses in detail question of colloidal solutions; silicate and its part in hardening of hydraulic binders; hydraulic lime; tensile strength, specifications.

MOTOR BUSES

Design and Operation. Principles of Motorbus Design and Operation, G. A. Green. Soc. Automotive Engrs. Jl., vol. 11, no. 1, July 1922, pp. 13-26, 36 figs. Safety, comfort and convenience, minimum operating cost and subdivisions of each commented on. Trucks or automobiles cannot render as good service as buses.

Principles of Motor Bus Design and Operation, David Beecroft. Commercial Vehicle, vol. 26, no. 11, July 1, 1922, pp. 12-14, 3 figs. Principles that apply to big Fifth Avenue buses apply also to all buses, everywhere, why design is big factor in successful bus operation. Review of paper presented by Col. Green at semi-annual mtg. of Society of Automotive Engrs.

Developments. Characteristics of Present-Day Buses, R. E. Plimpton. Bus Transportation, vol. 1, no. 7, July 1922, pp. 375-378, 3 figs. Requirements for city, inter-city, and country service considered; comfort and convenience factors found in modern bodies, devices for fare collection now being installed. (Abstract.) Paper read before Soc. Automotive Engrs.

New York State. Turnpikes Turn to Bus Routes in Empire State. Bus Transportation, vol. 1, no. 7, July 1922, pp. 383-389, 2 figs. Maps and tables of statistics and résumé of bus routes and facilities of New York State.

MOTOR TRUCKS

Steam. A Steam Six-Wheeler. Motor Transport, vol. 34, no. 904, June 26, 1922, p. 781, 3 figs. Two-wheeled conversion attachment to Ransomes steam wagon which is said to afford enormous carrying capacity.

A Milestone in Steam Design. Motor Transport, vol. 34, no. 904, June 26, 1922, pp. 768-771, 8 figs. New 7-ton Yorkshire, employing steam power in conjunction with many of best features of gasoline-car practice.

Tipping Gears. Tipping Gears for Motor Lorry Bodies, W. Erskine Dommett. Eng. Rev., vol. 35, no. 12, June 1922, pp. 406-412, 15 figs. Manner in which mechanical and hydraulic types have accomplished speed of operation, angle of tilt, ease when manually actuated, lightness, reliability, and low cost.

N

NITRIC ACID

Manufacture, Saltpeter vs. Synthetic Ammonia. Nitric Acid from Saltpeter or Synthetic Ammonia, Guy B. Taylor. Chem. Age (N. Y.), vol. 30, no. 6, June 1922, pp. 244-246, 1 fig. Cost factors and conditions that will determine raw material of nitric acid manufacture.

NITROGEN

Fixation. The Fixed Nitrogen Research Laboratory. Chem. Age (N. Y.), vol. 30, no. 6, June 1922, pp. 266-267, 4 figs. Equipment and facilities of plant at American University, Wash., D. C., and government work carried on there.

Synthetic, Products. Synthetic Nitrogen Products and the Ammonia Obtained as By-Product in Coal Distillation (Les produits azotés synthétiques, et l'ammoniaque obtenus comme sous-produits de distillation de la houille), A. Grebel. Génie Civil, vol. 80, no. 25, June 24, 1922, pp. 567-570. Influence of different phases of recovery and treatment of ammonia on final yield of sulphate.

NON-FERROUS METALS

Gas Absorption and Oxidation. Gas Absorption and Oxidation, B. Woyski and John W. Boeck. Foundry, vol. 50, no. 14, July 15, 1922, pp. 571-573, 2 figs. Defects in non-ferrous metals caused by gas absorption often erroneously attributed to oxidation; defective metal brought back to normal by proper melting practice; oxides of low gravity remain in metal. Paper read before Am. Inst. Min. & Met. Engrs.

NUMBERS

Duodecimal System. Standardization of Numbers (Die Normung des Zahlenmasses), Alfred Sieber. Maschinenbau, vol. 1, no. 5, June 10, 1922, pp. 280-284, 4 figs. Disadvantages of decimal system and advantages of duodecimal system.

O

OIL

Briquetting. Solid Oil With Peat Vehicle, Wm. A. Hall. Petroleum Times, vol. 8, no. 184, July 15, 1922, p. 90. Brief description of method of producing solid oil with peat as vehicle.

Protection from Evaporation. Durable Foam Seal Stops Evaporation and Reduces Fire Risk, Paul Truesdell. Nat. Petroleum News, vol. 14, no. 28, July 12, 1922, pp. 43-44, 1 fig. Sealite, compound containing 50 per cent air, cornstarch, glycerine and gelatine and other ingredients, when poured over top of tank of oil, spreads over surface, forming floating seal which prevents evaporation and fire.

OIL ENGINES

Bolinda. Bolinda Oil Engines of New Type. Shipping, vol. 16, no. 1, July 1922, pp. 42-43, 1 fig. New fuel injection device fitted on top of ignition bulb from which fuel is sprayed downward toward piston thereby eliminating fresh-water and compressed-air injection for maintaining constant hot-bulb temperature.

Design. The Oil Engine of Today, Chas. E. Lucke. Power, vol. 56, no. 7, Aug. 15, 1922, pp. 241-243, 2 figs. Discussion of recent improvements in general design that have made oil engine thoroughly reliable, including fuel charging and cylinder cooling.

Heavy-Oil. Present State of Heavy-Oil Engines (État Actuel de la Question des Moteurs a Huile Lourde), Marcel Bochet. Mémoires et Compte Rendu des Travaux de la Société des Ingénieurs Civils de France, vol. 75, no. 1-3, Jan.-Mar. 1922, pp. 87-105, 15 figs. partly on supp. plates. Discusses marine engines used in various shipyards; describes semi-Diesel engine and its operation.

Marine. Types of Large Marine Oil Engines, David R. Hutchison. Inst. Mar. Engrs. Trans., vol. 34, Apr. 1922, pp. 1-30 and (discussion) 31-37, 21 figs. Novel features of Scott-Still engine as representing newest types. Operating cycles and fuel economy; cylinder charging and exhausting; combustion of fuel; cooling; framing; valve and maneuvering gear.

Operation. Oil Engine Hints, Bert Bare. Power Plant Eng., vol. 26, no. 14, July 15, 1922, pp. 704-707, 2 figs. Hot ignition; missing; hunting; failure to start; loss of compression; compression card.

OIL FUEL

Ships. Oil Fuel In Ships. Steamship, vol. 34, no. 397, July 1922, pp. 21-24, 6 figs. Many advantages of oil coal and review of some features of oil burning.

Vegetable. Using Vegetable Oils for Fuels (Utilisation des huiles végétales comme combustibles industriels), Maurice Leduc. Chaleur et Industrie, vol. 3, no. 25, May 1922, pp. 1277-1280. Their calorific power; French vegetable oils; unlimited production; use in oil-burning installations.

OFFICE MANAGEMENT

Staff Training. Scientific Organization of Work at the Factory (Contribution au problème de l'organisation scientifique du travail dans les ateliers), Gaston Vidal. Arts et Métiers, vol. 75, no. 20, May 1922, pp. 129-141, 12 figs. Activities of National Schools of Arts and Trades in training office workers.

OPTICAL INSTRUMENTS

Screw and Gear Inspection. Inspecting by Optical Projection. Machy. (N. Y.), vol. 28, no. 12, Aug. 1922, pp. 984-988, 6 figs. Description of methods, with particular data on screw and gear inspection.

P

PAINTS

Physical Properties. Some Physical Properties of Paints, P. H. Walker and J. G. Thompson. Ry. Rev., vol. 71, no. 3, July 15, 1922, pp. 76-81, 2 figs. Investigations by U. S. Bur. Standards presented at convention of Am. Soc. for Testing Matls.

Sulphate Pulp, Lined Digesters. Sulphate Pulp Made in Lined Digesters, P. C. Austin. Paper, vol. 30, no. 16, June 21, 1922, pp. 14 and 16. Prevention of leaks, improved yield and steam economy among advantages. Paper read before joint convention of Cost Assn. of Paper Industry and Am. Pulp & Paper Mill Superintendent's Assn.

PAPER MANUFACTURE

Starch, Use of. The Use of Starch in Paper Manufacture, W. A. Nivling. Paper Mill, vol. 46, no. 26, July 8, 1922, pp. 4-6 and 8, 11 figs. Consideration of various starches and their differences in sizing operation. Paper read at Superintendents' Convention.

PARACHUTES

Calthrop. A New Calthrop Parachute Development. Flight, vol. 14, no. 28, July 13, 1922, pp. 396-397, 4 figs. Parachute equipped with series of slots near periphery with flounces which deflect air escaping through them at desired downward angle.

PEAT

Boiler Firing. Experience With Peat Firing of Steam Boilers (Erfahrungen über die Verheizung von Torf im Dampfkesselbetriebe), Ph. Stauf. Zeit. des Bayerischen Revisions-Vereins, vol. 26, no. 13, July 15, 1922, pp. 103-106, 4 figs. Composition and calorific value of peat; suitability of furnaces for peat; comparative figures as to cost.

PIPE, CAST-IRON

Analysis and Selection. Getting Best Results with Cast Iron Pipe, F. A. McInnis. Fire & Water Eng., vol. 72, no. 5, Aug. 2, 1922, pp. 221-222. Practical suggestion as to selection of pipe including analyses as to sulphur content made in Boston and elsewhere.

PIPE LINES

Design. Pipe Lines (Rohrleitungen), M. Fränkl. Maschinenbau, vol. 1, no. 6, June 24, 1922, pp. 343-346, 5 figs. Essential points in pipe-line installations; most economic kind of pipe; most suitable design of a given installation.

PIPE, WOOD

Notes on. Some Observations Concerning Wood Pipe, J. W. Ledoux. Am. Water Works Assn. Jl., vol. 9, no. 4, July 1922, pp. 549-569. Cost design in particular; formula for strength; water hammer discharging capacity; comparison of wooden and cast-iron pipes.

PISTON RINGS

Manufacture. Development of Piston Rings (Das Wesen und die Ausbildung der Kolbenringe mit Rücksicht auf wirtschaftliche Fertigung und auf Dichtigkeit gegen Druck), Otto Graf. Maschinenbau, vol 1, no. 6, June 24, 1922, pp. 339-343, 11 figs. Old and new ways of production; deformation by hammering; testing of materials; dimensions of rings for ordinary and light-metal pistons, standardization.

POWER PLANTS

Austria. The Partenstein Power Plant (Das Kraftwerk Partenstein), Adolf Kvetensky. Elektrotechnik u. Maschinenbau, vol. 40, nos. 20 and 21, May 14 and 21, 1922, pp. 229-236 and 242-246, 13 figs., May 14: Describes construction of plant and its equipment and makes calculations as to its profitability. May 21: Describes machinery equipment including Francis spiral turbines, three-phase generators, transformers, switchboard arrangements, erection of poles for overhead lines.

Birmingham, Nechells Station. Electricity Supply in Birmingham. Electrician, vol. 88, no. 2301, June 23, 1922, pp. 744-750, 7 figs. Details of 105,000-kw. ultimate capacity station started before war and now reaching completion.

Development. Notes from Report of Prime Movers Committee of N.E.L.A. Power Plant Eng., vol. 26, no. 14, July 15, 1922, pp. 697-703, 9 figs. Résumé of development in power-plant engineering during past year.

Prairie du Sac, Wis. Increased Capacity at Prairie du Sac. Power Plant Eng., vol. 26, no. 14, July 15, 1922, pp. 687-693, 15 figs. Addition of four 60-cycle, 23000-v., generators which increase output by 12,000 kva. and auxiliary changes in connection therewith.

Steam Conditions. The Choice of Steam Conditions in Modern Power Stations, L. C. Kemp. Electrician, vol. 88, no. 2302, June 30, 1922, pp. 774-777, 4 figs. Investigation indicating that more careful selection of steam conditions should be encouraged.

POWER TRANSMISSION

Radiotelegraphic. The Problem of Radiotelegraphic Power Transmission (Étude sur le problème de la téléméeanique par T. S. F.), Maurice Guéritot. Onde Electrique, vol. 1, no. 3, Mar. 1922, pp. 141-151, 3 figs. Reviews work done in transmitting power by radio to perform certain work at a distance,

especially French investigations during war, and discusses difficulties of control at a distance.

PRODUCER GAS

Analysis and Composition. Producer Gas (Der Generatorgaskörper), E. Kraemer. Feuerungstechnik, vol. 10, nos. 17, 18 and 19, June 1, 15 and July 1, 1922, pp. 185–188, 199–203, and 211–214, 16 figs. June 1: Analysis and composition; gives table of limit values for CO_2, CO, H_2, and CH_4. June 15: Calculations and curves of planes of equal quantities of air, equal quantities of steam, equal temperatures, and equal efficiency. July 1: Discusses neutral plane dividing gas into two parts, one containing exothermic processes and other endothermic processes. Greatest methane content.

PULVERIZED COAL

Boiler Firing. Pulverized Coal Firing (Die Staubverbrennung), A. B. Helbig. Feuerungstechnik, vol. 10, no. 19, July 1, 1922, pp. 209–211, 2 figs. Describes various systems of feeding pulverized coal to combustion chamber.

Explosion Hazard. Pulverized Coal Is Dangerous on the Surface as Well as Underground; Precautions to be Taken in Handling It, L. D. Tracy. Coal Age, vol. 22, no. 5, Aug. 3, 1922, pp. 164–168, 5 figs. Precautions to prevent explosion, particularly with reference to driers and electrical devices; data on self-ignition. From paper read before Fire Chiefs' Club of Ohio.

Feeding. Principles of Feeding Pulverized Fuel, M. W. Arrowood. Combustion, vol. 7, no. 1, July 1922, pp. 31–34, 47, 6 figs. Consideration of proper method of injection to obtain best conditions at various points in furnace.

Household Furnaces. Burning of Powdered Coal in Household Furnaces, Thos. W. Atterbury. Engrs. & Eng., vol. 39, no. 6, June 1922, pp. 209–214, 1 fig. Reasons for adoption; present low efficiency of household furnaces; convenience of pulverized usage; smoke prevention; description of installation and costs.

Lead Smelter. Pulverized Coal at the Bunker Hill and Sullivan Smelter, Henry M. Payne. Eng. & Min. Jl.-Press, vol. 114, no. 4, July 22, 1922, pp. 149–151, 5 figs. Use of powdered fuel in Northwestern lead smelter proving to be more economical than oil; plant operates with minimum amount of attention; safety precautions taken.

R

RAILS

Bull-Head. Specification for Bull-Head Rails. Iron & Coal Trades Rev., vol. 105, no. 2836, July 7, 1922, p. 5. Specifications issued by British Eng. Standards Assn.

Wear. The Corrugation of Rails (Usure ondulatoire des Rails), M. E. Resal. Industrie des Tramways, Chemins de Fer et Transports Publics Automobiles, vol. 16, no. 181, Jan. 1922, pp. 10–17, 13 figs. Discusses question in connection with rolling of metal which may be responsible for the corrugation, and advises experiments to be made, especially to prove connection.

RAILWAY ELECTRIFICATION

France. Electrification in France, M. Sabouret, Elec. Ry. & Tramway Jl., vol. 46, nos. 1130 and 1136, May 12 and June 16, 1922, pp. 212–214 and 278–280, 5 figs. Report of chief engr. of Orleans Ry. Co. to Internat. Ry. Congress at Rome showing plans for 5000 miles to be electrified.

Main-Line Railroads. Electrification of Main Line Railroads, S. T. Dodd. Gen. Elec. Rev., vol. 25, no. 7, July 1922, pp. 439–440. Outstanding features of accomplished and contemplated installations.

Russia. Electrification Possibilities in Russia (Ruslands elektrificeringsmuligheter), E. Kraabel-Jörstad. Elektroteknisk Tidsskrift, vol. 35, no. 20, July 15, 1922, pp. 159–162. Plans for electrification at Moscow and Petrograd; water-power resources of Russia in Europe and Asia.

Trend of Development. The Electrification of Railways, F. Rowlinson. Beama, vol. 10, nos. 5 and 6, May and June 1922, pp. 349–357 and 437–444, 12 figs. Outstanding features of successful installation and facts to be considered in prospective ones.

RAILWAY OPERATION

Service of Supply. The Origin and Development of the Service of Supply, George G. Yeomans. Ry. Rev., vol. 70, nos. 23 and 24, vol. 71, no. 1, June 10, 17 and July 1, 1922, pp. 868–869, 923–927 and 12–15. Short history of most recent fundamental development in railway organization.

Train Control. Automatic Stopping of Trains and Repetition of Signals in the Cabs (Arrêt automatique des trains et Répétition des signaux sur les locomotives), J. Verdeyen. Annales de l'Association des Ingénieurs Sortis des Écoles Speciales de Gand, vol. 12, no. 1, 1922, pp. 16–32. Reviews literature on subject. Reply by C. Van de Velde, pp. 33–48, 1 fig.

British Approve Automatic Train Control. Ry. Age, vol. 73, no. 4, July 22, 1922, pp. 149–153, 2 figs. Ministry of Transport Committee recommends intermittent contact type; disapproves of speed control.

RAILWAY REPAIR SHOPS

Santa Fe Ry. Santa Fe Completes Modern Shops at Albuquerque. Ry. Age, vol. 73, no. 6, Aug. 5, 1922, pp. 237–242, 10 figs. Description of locomotive repair building.

RAILWAY SHOPS

Canadian Pacific at Angus. How Shop Output is Increased and Costs Reduced at Angus. Ry. Rev., vol. 70, no. 23, June 10, 1922, pp. 851–865, 19 figs. Organization and equipment and expression of value of effective shop scheduling system.

Car. Equipment and Operation of a Modern Steel Car Plant, Geo. A. Richardson. Ry. Rev., vol. 70, no. 24, June 17, 1922, pp. 913–918, 8 figs. Plant of Cambria Steel Co., Johnstown, Pa., which is integral part of steel manufacturing organization; capable of building 50 all-steel cars a day.

RAILWAY SIGNALING

Electric. Electric Control of Railway Switches and Signals (La commande électrique des grands postes d'aiguilles et signaux de chemins de fer), Lucien A.-H. Pahin. Révue Générale de l'Électricité, vol. 12, no. 1, July 8, 1922, pp. 23–31, 10 figs. Interior arrangement of electric signal cabins on French railways; describes in detail construction and operation of motor applied to each individual switch.

Locomotive Cab Signals. On the Question of Locomotive Cab Signals, Faustino Villa. Int. Ry. Assn. Bul., vol. 4, no. 5–6, May-June 1922, pp. 821–862, 17 figs. Classifications and functions; mechanical, electrical and electromechanical repeating apparatus.

Sweden. Safety and Signaling Installations on the Cristiania-Gjövik Line (Sikrings- og signalanlaeg ved Roa stasjon, Kristiania-Gjövikbanen), J. Lindboe. Teknisk Ukeblad, vol. 69, no. 26, June 30, 1922, pp. 246–250, 9 figs. Describes in detail signaling arrangements, electric power, wiring and connections, switching, electric motors, etc.

RAILWAY SWITCHES

Remote Operation. Remote Operation of Switches on the New Haven. Ry. Age, vol. 73, no. 6, Aug. 5, 1922, pp. 251–252, 6 figs. Satisfactory results are reported after 40 years experience with 28 low-voltage machines.

RAILWAY TERMINALS

Operation. Terminal Stations for Passengers, L. Maccallini. Int. Ry. Assn. Bul., vol. 4, no. 5–6, May-June 1922, pp. 753–761. Best arrangements to reduce number of movements of engines and empty cars.

St. Louis. Report on Improvement of Railroad Terminals in St. Louis. Ry. Rev., vol. 71, no. 4, July 22, 1922, pp. 99–113, 7 figs. Report on team track facilities.

RAILWAY TIES

Reinforced-Concrete. Note on Some Recent Types of Reinforced Concrete Sleepers, R. Desprets. Int. Ry. Assn. Bul., vol. 4, no. 7, July 1922, pp. 959–971, 6 figs. Investigation of Calot type tried by Paris-Orleans Ry. Co. and Vagneux type tried by Paris-Lyons-Mediterranean Ry. Co. Latter is less expensive.

RAILWAY TRACK

Effect of Rolling Stock on. Action and Reaction Between Rolling Stock and Track (Considérations générales sur les actions réciproques de la voie et du matériel roulant et sur le calcul des rails), R. Desprets. Annales des Travaux Publics de Belgique, vol. 13, no. 2, Apr. 1922, pp. 233–272, 6 figs. Analyzes forces and stresses, vertical, longitudinal and lateral action, and makes calculations of rails on this basis.

REAMERS

Standardization. Standardizing Shell Reamers and Arbors, H. S. Kartsher. Machy. (N. Y.), vol. 28, no. 11, July 1922, pp. 892–895, 7 figs. Standard dimensions governing fits, and gages used for inspection.

REFRACTORIES

Fireclay. Fireclay Refractories, C. E. Bales. Nat. Engr., vol. 26, no. 7, July 1922, pp. 300–303, 3 figs. Origin and occurrence of fireclay; mining and preparation for use; relation to boiler practice. Paper read before Kentucky No. 1, N.A.S.E.

Research. Report of the Refractory Materials Research Committee. Gas Jl., vol. 158, no. 3085, June 28, 1922, pp. 840–851 and (discussion) 851–852, 4 figs. Revision of British specification. Standardization of After-Contraction Test, by D. A. Jones. Thermal Conductivity of Refractory Materials at High Temperatures, by A. T. Green.

REFRIGERATING MACHINES

Turbo-Compressor. A New Refrigerating Machine. Ice & Refrigeration, vol. 63, no. 1, July 1922, pp. 43–45, 2 figs. Novel turbo-compressor using newly discovered low-pressure refrigerating fluid demonstrated before gathering of 300 engineers at plant of Carrier Engr. Corp., Newark, N. J., machine especially adapted for producing cold water required in cooling air for industrial purposes.

RELATIVITY

Application in Heat Industries. The New Mechanics and Their Application in Heat Industries (La Mécanique nouvelle et ses applications pratiques aux industries du feu), P. Drosne. Chaleur et Industrie, vol. 3, nos. 21, 22, 23, 24, 25 and 26, Jan., Feb., Mar., Apr., May and June, 1922, pp. 882–886, 971–975, 1070–1076, 1165–1169, 1270–1273 and 1368–1372, 6 figs. Application of theory of relativity to calculation of zones of combustion and transformation; kinetic and atomic theories; electrons and ionization; molecular isotropic law; occlusion of gases. Concludes that new mechanics give remarkably accurate picture of underground equilibrium of natural hydrocarbons.

RIVETING

Hammers for. Operations with Riveting Hammers. Machy. (Lond.), vol. 20, no. 511, July 13, 1922, pp. 453–455, 6 figs. Examples of cold-heading and rivet-setting operations performed on high-speed riveting hammers.

ROLLING MILLS

Reversing Passes. Layout and Arrangement of Reversing Passes in Rolling Mills (Unterwerke für Umkehrwalzenstrassen), H. Baclesse. Elektrotechnische Rundschau, vol. 39, no. 1, Jan. 31, 1922, pp. 1–5, 9 figs. Electric equipment and its advantageous location and arrangement.

Sheet Mills, Reconstruction. Reconstruction of Ayrton Sheet Mills, Middlesbrough. Iron & Coal Trades Rev., vol. 104, no. 2835, June 30, 1922, pp. 967–969, 8 figs. Description of installations including gas firing for all mill furnaces.

RUBBER

Lime as Accelerator. Prepared Lime in Rubber, H. L. Terry. Rubber Age, vol. 3, no. 5, July 1922, pp. 211–212. Preparation of lime for use as inorganic accelerator in rubber industry; qualities of and impurities in lime.

Manufacture. The Rubber Industry (L'Industrie du caoutchouc), F. Jacobs. Révue Industrielle, vol. 52, nos. 4, 5, 6, 7 and 8, Feb., Mar., Apr., May and June 1922, pp. 117–233, 165–166, 194–198, 220–222 and 256–262, 21 figs. Feb.: Preparation of mixtures; washing and drying of rubber; mixing and mixers; calendering; etc. Mar.: Discusses various methods and apparatus for vulcanizing rubber Apr.: Production of manufactured articles, such as belting, erasers, sponges, etc. May: Manufacture of rubber goods, such as gas tubes, tobacco pouches, rubber bands, etc. June: Manufacture of pneumatic tubes. Continuation of serial.

Microscopic Examination. The Microscope in the Rubber Industry, W. M. Ames. Rubber Age, vol. 3, no. 5, July 1922, pp. 213–214 and 217–218, 7 figs. Laboratory requirements and definite determination of structure and characteristics.

S

SCAFFOLDS

Suspended. Suspended Scaffolds for Building Construction. Contractors' & Engrs.' Monthly, vol. 4, no. 6, June 1922, pp. 45–46, 2 figs. Description of "Little Wonder" suspended scaffold, which is claimed to reduce possibilities of accidents.

SCREW THREADS

Tolerances. Screw Tolerances (Gewindetoleranzen), G. Berndt. Werkstatts Technik, vol. 16, no. 12, June 15, 1922, pp. 349–356. A compilation of material from all countries on tolerances for bolts, nuts, etc.

SEMI-DIESEL ENGINES

Construction and Application. The Semi-Diesel Engine, Its Construction and Application (Les moteurs semi-Diesel, état actual de leur construction et de leur utilisation), Adrien Schubert. Bul. de la Société d'Encouragement pour l'Industrie Nationale, vol. 134, no. 5, May 1922, pp. 418–505, 78 figs. Indicator diagrams; efficiency; fuel injection; water injection; ignition; starting; fuels, including vegetable oils; present types. Bibliography.

SEMI-STEEL

Properties and Use. Semi-Steel, J. Cameron. Metal Industry (Lond.), vol. 30, no. 26, June 30, 1922, pp. 623–629, 6 figs. Definition, field for use, tests and raw materials for production, heat treatment. Paper read before Insto. British Foundrymen. See also Foundry Trade Jl., vol. 25, no. 306, June 29, 1922, pp. 495–500, 6 figs.

SHELLAC

Origin, Utilization and Examination. Shellac Its Origin, Utilization and Examination (Der Schellack, seine Entstehung, Verarbeitung und Untersuchung), Hans Wolff. Chemiker-Zeitung, vol. 46, nos. 35 and 38, Mar. 23 and 30, 1922, pp. 265–266 and 291–293, 2 figs. Mar. 23: Production; types on market; bleaching and solubility. Mar. 30: Chemical composition, properties; uses.

SMOKE ABATEMENT

Paris. The Smoke Question in Industrial Centers (La question des fumées dans les agglomérations industrielles). Journal des Usines a Gaz, vol. 46, n. 11, June 5, 1922, pp. 161–167, 2 figs. Gives text of Paris police regulations to prevent smoke, and progress in their application.

SOLDERS

Aluminum. Tests of Aluminum Solders. Automotive Industries, vol. 47, no. 4, July 27, 1922, p. 168. Data on tests on soldered joints made at McCook Field.

Metallurgical Investigation. A Metallurgical Investigation of Solders, Wallace Dent Williams. Raw Material, vol. 5, no. 6, July 1922, pp. 216–223, 6 figs. Fusibility; scratch hardness; low melting point for white metals; silver solders; autogeneous soldering; borax substitutes.

SPRINGS

Helical. A Coiling and Heat Treating Plant for Helical Springs, William J. Merten. Am. Soc. for Steel Treating Trans., vol. 2, no. 11, Aug. 1922, pp. 977–983, 5 figs. Main features of plant for insuring maximum economy of labor and materials consistent with securing high-grade product.

The Cadman "Gato" Valve

The Cadman GATO Valve is standard equipment with the leading boiler manufacturers, oil refineries, and public utilities the world over, because of its unique features.

It is locked positively tight by a simple mechanical movement when closed, yet is easily opened or closed under all conditions by the slightest pressure on the quarter turn lever.

The provision of a ready means of adjustment ensures a life many times that of the ordinary plug valve. It is practically indestructible.

The GATO Valve possesses many advantages over any other of this type. These advantages are fully described in our new catalogue just off the press. A copy should be in the hands of every engineer and the coupon brings it.

Leaf. Leaf Springs (Ressorts a Lames superposées), C. Reynal. Arts et Métiers, vol. 75, no. 21, June 1922, pp. 164–173, 9 figs. Symmetrical and unsymmetrical springs; length, thickness and flexibility of leaves, and their calculation; sensitiveness of springs

Manufacture. Single-Stroke Eye-Rolling Machine for Automobile Springs. Machy. (Lond.), vol. 20, no. 513, July 27, 1922, pp. 522–523, 5 figs. Description of machinery built in England.

STEAM ACCUMULATORS

Ruths. Steam Accumulators (Dampfspeicher), Johannes Ruths. Zeit. des Vereines deutscher Ingenieure, vol. 66, nos. 21, 22 and 24, May 27, June 3 and 17, 1922, pp. 509 513, 537–542 and 597–605, 62 figs. May 27: Construction and application of Ruths accumulator; possibility of equalizing pressures with various boiler types; plants already built; use of these accumulators in new constructions or extensions of present plants. June 3: Cooling losses, water-level indicators; superheat accumulators. June 17: Existing installations of steam accumulators for equalizing variations in steam for boiling and heating, and for equalizing power and steam variations.

The First Ruths Steam Accumulator in Germany (Der erste Ruths-Dampfspeicher in Deutschland), Theodor Stein. Stahl u. Eisen, vol. 42, no. 24, June 15, 1922, pp. 924–933, 9 figs. Describes steam-accumulator installation in power plant of Lauchhammer Iron Works, fluctuations in load, construction details, and particulars of cost.

STEAM ENGINES

Automatic Control. Steam Engines With Automatically Controlled Steam Supply (Dampmaskiner med automatisk regulerbar dampudtagning), H. H. Mansa. Ingeniören, vol. 31, no. 30–31, May 27, 1922, pp. 189–194, 11 figs. Steam consumption and steam economics at factories using large amount of steam.

Flywheel, Degree of Irregularity. Graphical Determination of the Degree of Irregularity of an Engine (Calcul graphique du degré d'irrégularité d'une machine), G. Laville. Révue Générale de l'Électricité, vol. 12, no. 3, July 22, 1922, pp. 85–91, 10 figs. Method for determining moment of inertia of flywheel of machines as function of degree of irregularity.

Schmidt 60-Atmos. The Schmidt 60-Atmos. Steam Engine and the Use of High-Pressure Steam in Lignite Mines (Die Schmidtsche 60-Atmosphären-Dampfmaschine und die Anwendung höchstgespannten Dampfes auf Braunkohlenbergwerken), Otto H. Hartmann and Kurt Manning. Braunkohle, vol. 20, nos. 49, 50 and 51, Mar. 11, 18 and 25, 1922, pp. 769–776, 790–795 and 805–811, 30 figs. Mar. 11: Describes vertical tube boiler developed by Schmidt's High-Temperature Steam Co., in Kassel and gives results of experiments with maximum pressure boilers. Mar. 18: Consumption of heat of maximum-pressure reciprocating engines and turbines. Mar. 25: Advantages of maximum-pressure engines in plants utilizing waste steam.

STEAM METERS

Chemical Measurement. Measuring Steam by Chemical Means (Het meten van stoom langs chemischen weg), J. Rutten. Chemisch Weekblad, vol. 19, no. 21, May 27, 1922, pp. 229–232, 1 fig. Chemical method for measuring steam at factories where steam is largely used in various departments, which gives much more exact results than ordinary metering systems.

STEAM TURBINES

Construction. Flow of Steam and Construction of Large Steam Turbines (Strömungsvorgänge und Aufbau grosser Dampfturbinen), G. Zerkowitz. Zeit. des Vereines deutscher Ingenieure, vol. 66, nos. 22 and 23, June 3 and 10, 1922, pp. 533–536 and 561–565, 15 figs. Expansion between blades; maximum performance of flow; incomplete expansion; influence of length of blades; means of reducing wear in parts; construction of steam turbines of large capacity.

Design. Modern Steam Turbines (Les turbines à vapeur modernes), Alb. Schlag. Révue Universelle des Mines, vol. 13, nos. 2, 3, 4 and 5, Apr. 15, May 1, 15 and June 1, 1922, pp. 95–100, 189–198, 265–272 and 351–358, 15 figs. Apr. 15: Actual state of steam-turbine industry; reaction and impulse types. May 1: Principal factors influencing construction of large turbines; security of operation; efficiency; dimensions; weight and cost, etc. May 15: Power and steam consumption. June 1: Maximum power of turbines at a given speed; accidents with large turbines; lubrication.

Disks, Calculation of. Contribution to the Exact Calculation of Steam Turbine Disks with Variable Thickness (Beitrag zur genauen Berechnung der Dampfturbinenscheibenräder mit veränderlicher Dicke), Alexander Fischer. Zeit. des Oesterr. Ingenieur- u Architekten Vereines, vol. 74, nos. 9–10 and 15–16, Mar. 3 and Apr. 14, 1922, pp. 46–49 and 71–73, 2 figs. Presents solution of the Stodola differential equation of radial displacement of rotating disks.

Hell Gate Station. Turbines at the Hell Gate Station. Power, vol. 56, no. 6, Aug. 8, 1922, pp. 194–199, 7 figs. Description of four main units which consist of two 40,000-kw. Westinghouse and two 35,000-kw. Gen. Elec. turbines.

Refrigerating Plants. Steam Turbine in the Refrigerating Plant, W. F. Schaphorst. Refrigeration, vol. 30, no 2, Apr 1922, pp 27–28 and 42–44. Sixteen advantages over other types of prime movers.

STEEL

Alloy. See ALLOY STEELS.

Ball. Ball Steel, Hilton G Freeland. Am. Soc. for Steel Treating Trans., vol. 2, no. 10, July 1922, pp. 898–911 and (discussion) 911–917, 5 figs. Ball manufacturer's problems arising from quality of steel received, and effect on final product.

Cementite Spheroidizing. Spheroidizing of Cementite in Steel, H. C. Ibsen. Forging & Heat Treating, vol. 8, no. 7, July 1922, pp. 300–303, 9 figs. Results of tests on 1 per cent carbon steel show that long-time anneal is not necessary to obtain spheroidized structure; such steel reveals increased ductility and shock-resisting value.

Chromium. See CHROMIUM STEEL.

Crystal Structure X-Ray Study. X-Ray Studies on the Crystal Structure of Steel, A. Westgren and G. Phragmen. Engineering, vol. 113, no. 2942, May 19, 1922, pp. 630–634, 12 figs. partly on supp. plate. Photograms of α-iron at 1,100 deg. cent. and δ-iron at 1,425 deg. cent.; crystal structure of iron modifications; influence of carbon or space lattice of iron in hardened steels; crystal shape of cementite. Paper read before Iron & Steel Inst.

Crystallization, Delayed. On Delayed Crystallisation in the Carbon Steels: The Formation of Pearlite, Troostite and Martensite, A. F. Hallimond. Engineering, vol. 113, no. 2946, June 16, 1922, pp. 767–769, 1 fig. Development of principles which explain delayed critical points and corresponding structure in terms of supersaturation theory. Paper read before Iron & Steel Inst.

Requirements and Properties. Requirements and Properties of Steels (Konstruktionsforderungen und Eigenschaften des Stahles), K. Wendt. Zeit. des Vereines deutscher Ingenieure, vol. 66, nos. 24, 25 and 26, June 17, 24 and July 1, 1922, pp. 606–618, 642–648 and 670–674, 95 figs. Development of high-class steels; mechanical, chemical, physical and compound loads; behavior at high and low temperatures; heat treatment and alloying; formation of crystals; segregation and stresses; forging and rolling; course of fiber and steel; tensile strength; cross-sections.

Rock-Drill. Breakage and Heat Treatment of Rock Drill Steel. Eng. World, vol. 21, no. 1, July 1922, pp. 39–40. Progress report to members of Advisory Board to Bur. of Mines and Bur. of Standards.

Rustless. Investigation of Rustless Steels (Några undersökningar på rostfritt stål), Bengt Kjerrman. Jernkontorets Annaler, vol. 107, no. 4, 1922, pp. 133–149, 7 figs. Development of rust- and acid-resisting steels, their thermic-microscopic examination.

Tool. See TOOL STEEL.

STEEL, HEAT TREATMENT OF

Electric-Furnace. The Electric Furnace as it Affects Over-All Cost of Heat Treated Parts, C. L. Ipsen. Am. Soc. for Steel Treating Trans., vol. 2, no. 11, Aug. 1922, pp. 984–989, 9 figs. Points out advantages and economy of electric furnaces.

High-Speed Steel. The Toughness of High Speed Steels as Affected by Their Heat Treatment, Marcus A. Grossmann. Am. Soc. for Steel Treating Trans., vol. 2, no. 11, Aug. 1922, pp. 1001–1005, 5 figs. Results of measurements on high-speed steels of 18 per cent and 13 per cent tungsten type, hardened at temperatures ranging from 1700 deg. to 2250 deg. fahr.

STEEL WORKS

Power Systems. Power Systems and the Steel Industry, E. C. Stone. Iron & Steel Elec. Engrs. Assn., vol. 4, no. 6, June 1922, pp. 279–301 and (discussion) 302–320, 4 figs. Requirements for thoroughly reliable source of power supply, and consideration.

STOKERS

Underfeed, Low-Grade Fuel. The Underfeed Stoker Successfully Burns Low-Grade Fuel. Elec. Ry. Jl., vol. 60, no. 7, Aug. 12, 1922, pp. 221–225, 9 figs. High-ash, clinkering coal burned in specially designed underfeed stokers; operation features by flexibility, high efficiency, capacities up to 350 per cent.

SUPERHEATED STEAM

Power Plants. Superheated Steam a Factor in Power Plant Economy, R. A. Holme. Eng. World, vol. 21, no. 1, July 1922, pp. 35–38, 1 fig. Capacity and efficiency of equipment increased at moderate cost by installation of superheaters; savings in connection with all types of prime movers; advanced practice at Hell Gate.

Superheating. Superheating of Steam for the Purpose of Avoiding Condensation (Die Überhitzung des Dampfes zum Zwecke der Vermeidung von Kondensationen). Wärme u. Kälte-Technik, vol. 24, no. 12, June 15, 1922, pp. 139–141. Discusses superheating in detail; makes calculation of steam velocity in pipe lines.

T

TANKS

Calibration. A Rapid and Accurate Method for the Calculation of Storage Tanks, J W. McDavid. Chem. & Met. Eng., vol. 27, no 4, July 26, 1922, pp. 156–158, 1 fig. Description of apparatus for calibration of tanks.

TEXTILE INDUSTRY

Bleaching Without Boiling. New Process and Apparatus for Bleaching without Boiling. Color Trade Jl., vol. 11, no. 1, July 1922, p. 29, 2 figs. Method for bleaching of fine yarns and delicate fabrics by alternate use of pressure and vacuum.

Frame-Work Knitting Machinery. Frame Work Knitting Machinery, Robert Straube. Eng. Progress, vol. 3, no. 7, July 1922, pp. 141–147, 35 figs. Comparison of cloth weaving, frame-work knitting, and hand knitting; production of stitches on cotton knitting frame and formation of loops on circular frame; straight or flat frame and production of finished article on machines.

THERMIT WELDING

Process. Thermit Welding, J. H. Deppeler. Am. Welding Soc. Jl., vol. 1, no. 6, June 1922, pp. 33–36. Value of this method in all heavy operations.

TIME STUDY

Switzerland. Exact Determination of Working Time on the Basis of Time Observation (Die exakte Ermittlung von Arbeitszeiten auf Grund von Zeitbeobachtungen), A. Sonderegger. Schweizerische Bauzeitung, vol. 80, no. 1, July 1, 1922, pp. 5–8, 3 figs. Principles of time study and rate setting, especially those of Merrick; examples of calculations.

TOOL STEEL

Standardization. Tool Steel—Shall it be Standardized? Roy H. Davis. Raw Material, vol. 5, no. 6, July 1922, pp. 233–235. Arguments pro and con on substitution of analyses for tool-steel brands. Presented at Convention of Nat. Assn. of Purchasing Agents.

TOOLS

Press. Press Tool Operations in the Manufacture of Buckle Fittings, Albert Hind. Machy. (Lond.), vol. 20, no. 511, July 13, 1922, pp. 449–452, 4 figs. Details and operation of press tools for manufacture of metal brace or buckle fittings.

Straight-Form, Calculation. The Calculation of Straight-form Tools having Top Rake. Machy. (Lond.), vol. 20, no. 510, July 6, 1922, pp. 416–418, 4 figs. Method of using data given in Machinery's Handbook for figuring top rake on tools which are to cut tough and hard materials.

TRACTORS

Belt Speeds. Considerations Affecting Belt Speeds, A. B. Welty. Agricultural Eng., vol. 3, no. 7, July 1922, pp. 115–116. Data with view to determine ideal belt speed for any particular type and size of tractor.

Reactions to Hitches. Tractor and Plow Reactions to Various Hitches, O. B. Zimmerman and T. G. Sewall. Soc. Automotive Engrs. Jl., vol. 11, no. 1, July 1922, pp. 107–115 and (discussion) 115–116, 17 figs. Reactions explained with special reference to slope and cross furrows; stability analyzed.

TURBO-COMPRESSORS

High-Speed Airplane. Turbo-Compressors for High-Speed Aviation, A. Rateau. Engineering, vol. 114, nos. 2951 and 2952, July 21 and 28, 1922, pp. 91–94 and 123–125, 9 figs. Discussion of design; specific pressures and weights of air under normal atmospheric conditions. Paper read before Instn. Mech. Engrs.

V

VISCOSITY

Determination. Viscosity Determination by Means of Orifices and Tubes, W. N. Bond. Physical Soc. of Lond. Proc., vol. 34, Part 4, June 15, 1922, pp. 139–144, 1 fig. Investigation of corrections applicable to determination of viscosity due to abnormal flow at ends of tubes. Expressions for end-corrections.

Determination for CO_2, N_2O, CO and N_2. Viscous Properties of CO_2, N_2O, CO and N_2, C. J. Smith. Physical Soc. of Lond. Proc., vol. 34, Part 4, June 15, 1922, pp. 155–165, 2 figs. Direct comparisons by observing time required by mercury pellet across equal volumes of gas through capillary tube. Mean area of collision deduced from Chapman's formula.

W

WATER POWER

Resources Index Inventory System. Water Resources Index Inventory Filing System. Can. Engr., vol. 42, no. 27, July 4, 1922, pp. 667–671, 3 figs. Method developed by Dominion Water Power branch for recording, collating and analyzing water resources data; coöperative investigations with provincial organizations; both graphical and written records.

WATERWAYS

St. Lawrence River. Possibilities of St. Lawrence Seaway, Wm. L. Saunders. Can. Engr., vol. 43, no. 2, July 11, 1922, pp. 128–130. Comparisons with other waterways; project economically sound; lower rates for water-borne freight power feature; would serve large population. From address before joint mtg. of A.I.E.E. and A.S.M.E.

WELDING

Pure Iron for. Manufacture and Use of Commercially Pure Iron in Gas and Electric Welding, C. A. McCune. Am. Welding Soc. Jl., vol. 1, no. 6, June 1922, pp. 8–23, 10 figs. Five characteristics of wires for successful welding.

[See also ELECTRIC WELDING; ELECTRIC WELDING, ARC; THERMIT WELDING.]

MECHANICAL ENGINEERING

Volume 44 November, 1922 No. 11

Ten Years' Progress in Management[1]

Management Stands as a Great Body of Knowledge and Practice to Facilitate the Operation of Industry —It is the Agency by which Community, State and Nation Shall Endure.

By L. P. ALFORD,[2] NEW YORK, N. Y.

TEN YEARS have passed since the Committee report on The Present State of the Art of Industrial Management was presented to The American Society of Mechanical Engineers. The request is now made for a review of the progress of management during the intervening decade. Unfortunately for the purpose of such a study, eight of these ten years were abnormal, many of the management changes and innovations introduced were of a temporary nature or were mere expedients, and it is difficult to separate them from other and more permanent developments.

The only satisfactory way to treat the review is to base it upon the report of 1912, which was well received and in large measure approved. This course has therefore been adopted.

At the outset we should recall and pay generous tribute to three of our late great leaders who aided in preparing that report and took part in its discussion: Frederick W. Taylor, the pioneer management; Henry L. Gantt, who humanized the movement; James M. Dodge, the earnest, constructive supporter. During our ten-year period these men of vision and power completed their life work.

To obtain information on the worth-while changes which have taken place, letters were written to management and industrial engineers, to executives of plants in various lines of industry, and to educators familiar with industrial developments. Many interviews were held with men having industrial and managerial responsibilities. The response to these requests has been most generous. The author is deeply indebted for the information received and expresses his sincere gratitude to all who have given aid.

The report of 1912 declared the new element in management to be: "The mental attitude that consciously applies the transference of skill to all the activities of industry." It also quoted[3] and endorsed three regulative principles:

a The systematic use of experience
b The economic control of effort
c The promotion of personal effectiveness.

New interpretations and expanded meanings have been given to these principles, but they have in nowise been weakened or susseded. One correspondent writes: "Note, for example, the nearly universal acceptance of the principles. . . ."

In answer to the question, "What steps have been made in the progress of management since 1912?" a wide range of opinion was expressed as shown by the following sixteen quotations from correspondents' letters. The first gives a particularly well-balanced judgment of the situation.

> It seems to me that management has very definitely progressed in the last ten years along certain main lines.
>
> In the first place, good management is more insistent today on knowledge as a basis of judgment, rather than the old judgment based on personal observation. Management is more and more demanding costs, a knowledge of inventories, monthly profit and loss statements, statistics, and records of all kinds as pictures of events on which to base judgment.
>
> In the second place, management is now undergoing a definite metamorphosis in the matter of industrial relations, and managers are waking up to the fact, as a practical element in their business, that they owe more to their employees than mere wages, and that whistle blow and hustle are not all there is to factory operation.
>
> It is this belief and the spirit developing, rather than the volume of the action up to date, which is a matter of very definite progress in the past ten years of management.

Ten opinions, three to the effect that management has retrogressed or made little or limited progress, and seven stating the belief that progress has been made and mentioning certain details of improvement, are grouped to present a contrasting though in the main favorable picture.

> Management (the directing group) has retrogressed in its acceptance of the principles of management, while labor has materially progressed toward a broader acceptance of these principles.

> I believe that very little progress has been made in the adoption of scientific-management principles in industries outside of metal working with a few notable exceptions.

> The main advance, and that lamentably slow, has been in putting into practice knowledge already available previous to 1912.

> During the past ten years, we have passed through the period of first glamour, then the reaction of a loss of confidence, and have finally evolved into the general recognition of the legitimate place of a new branch of engineering art and science—management engineering.

> The important steps in progress in management during the past ten years have been from unintelligent rule-of-thumb management, through scientific management to intelligent management. The latter has advanced steadily during the decade.

> The greatest progressive step has been toward standardization of appliances and methods.

> The most definite progress made during the past ten years is the universal acceptance of the merits of specialized production and standardization of design. These two steps have opened the way to a third simplification of method.

> The reaction from destruction and waste incident to warfare and reconstruction has been toward the elimination of waste in industry as a management function. Waste in all forms has been more closely observed than hitherto, especially during the past two years. The effort to do away with waste has led to the fixing of budgets and the determination of cost standards.

> Important steps in the progress of management since 1912 are:
>
> *a* Greater use of facts in the establishment of the standards by which business is conducted,
>
> *b* Broader recognition of the principle that industry exists for service to humanity,
>
> *c* Greater appreciation of the importance of regularization or control in the successful conduct of the industries,
>
> *d* Wider understanding of the economic value and importance of the management engineer in the operation of business.

> There has been a great increase in the use of specifications not only to govern purchased materials but also to attain uniformity of process, quality and cost, and thus to insure reliability of product. Many plants now have well-equipped laboratories staffed by scientific men and some regularly employ consulting scientists. In the larger corporations research laboratories are not uncommon. Few of these departments are over ten years old and they evidence a rapidly growing appreciation of pure science as a tool of management.
>
> The need of early and reliable figures as a mechanism of management has caused many companies to prepare monthly a complete statement of their business and earnings. A constantly increasing number of companies are publishing annually a detailed statement of their financial condition and many are publishing such statements quarterly. This voluntary publicity indicates a sincerity and frankness rare in management of an earlier decade.

---

[1] Brief reviews of recent developments in the United Kingdom and Germany which were also presented during Management Week, immediately follow the present paper.

[2] Editor *Management Engineering*. Mem. Am. Soc. M.E.

[3] *American Machinist*, vol 36, p. 857, The Principles of Management, by Church and Alford.

Presented during Management Week, Oct. 16–21, 1922. To be read by title at the Annual Meeting, New York, December 4 to 7, 1922, of THE AMERICAN SOCIETY OF MECHANICAL ENGINEERS. Abridged by the omission of 11 appendices. Copies of the complete paper may be obtained gratis on application. All papers are subject to revision.

The final quotations in regard to progress, five in number, discriminate between management form and substance. Progress is indicated in both of these aspects.

> The biggest and most lasting accomplishment in the inculcation of management principles is that, like religious teaching whose significance has been forgotten during years of prosperity, they again in the years of depression following the war developed a new significance in the minds of the thoughtful. A principle is not established in the actual social inheritance of the race—as a step forward—until man has applied it to himself and seen whether its application makes him a better man in his social relations. So management principles are being used as yardsticks to measure individual industrial development. This means that these principles are becoming a subconscious part of the mental equipment of industry, and not only is this real progress, it is fundamental.

> The development and use of the Gantt chart is the most important step of progress, because it calls attention to the movement of facts, to the necessity of basing decisions on facts rather than on opinions, and because it helps managers to foresee future happenings.
>
> A second important step is the change in the method of installation from the old type which organized from the top down to the new type which builds from the bottom up.
>
> A third important step is the development of the theory that the cost of an article includes only those expenses actually incurred in the production of the article, and that the expenses of maintaining one machine in idleness cannot be charged into the cost of the output of another machine. Along with this theory came the development of a method of arriving at costs of idleness and work.

> Probably the greatest progress consists in a better understanding of the problems of management with a particular acceptance of the facts to which Taylor called attention, that management is an art which may be practiced advantageously through the application of certain principles and the scientific method I do not think, as yet, that the great majority of men at the head of industries have anything like an adequate understanding of scientific management, nor that they are able to distinguish between form and substance in this respect. They have, however, apparently emerged from the attitude of opposition and mistrust of so-called scientific management, but are satisfied with a superficial application of the principles of management.

> The important steps of progress made in management since 1912, I would say, are as follows. The order in which they are named is not significant:
>
> *a* A greater appreciation of the human factor in industry.
>
> *b* The growing recognition that employees should have a voice in the management as relating to those questions that directly affect tham.
>
> *c* The recognition of the strategic position of shop foremen and the necessity of more carefully selecting and training them.
>
> *d* The increased recognition of the value of fundamental principles.
>
> *e* The recognition of, and in a large degree the adoption of, standard systems of cost accounting from the point of view of timeliness, as a barometer rather than history, as an instrument of production rather than a matter of finance.
>
> *f* A great development in mechanical equipment, combined with improved plant layout and building plants to fit manufacturing process.
>
> *g* A marked advance in sales policies.
>
> *h* A marked advance in substituting the trained, competent engineer for the old "cut-and-try" type of executive.

> Using figures, which after all are most impressive, but basing those figures purely on my impressions, I would say that since 1912 industry has progressed in management by some 30 to 40 per cent in the appreciation of the fact that there is a management problem aside from the old concept, which was that the owner had simply to censor the things that happened within his jurisdiction. I should say that there had been a 20 to 25 per cent endeavor to install the mechanisms of management, considering in this figure the generally known stores systems, operation studies, wage-incentive plans, etc. In some cases, as for instance in stores control, the percentage might run a great deal higher, but I am refraining from increasing my estimate for it is my belief that these mechanisms that we have installed are, for the most part, of a makeshift character, and that in industry as a whole and considering only the larger companies, I doubt if more than five or six per cent are possessed of mechanisms at all acceptable in the final scheme of what management should do and possess.
>
> As to the real concept existing today of what management is, and what conditions must be considered, influenced and coördinated to bring about the situation which should exist I doubt if more than one-fifth or one-fourth of one per cent of the companies in this country possess a knowledge or even appreciation of what is real management.

Combining and weighing these carefully prepared statements and adding to them certain well-recognized facts, there emerges a group of factors of varying importance which mark the progress of management during the past decade. These naturally arrange into three groups, of which the first concerns changes in mental attitude.

a The ancient controversy as to whether management is a science or an art has subsided, with increased recognition of the scientific basis of management.

b The attitude of opposition and mistrust toward management and the passionate antagonism to the installation of management methods have in general disappeared.

c Among those responsible for the carrying on of industry there has grown an appreciation of the existence of problems of management. (The appointment of Herbert Hoover as Secretary of Commerce and General Dawes as Director of the Budget reflect an appreciation by the Government of the need for management in our national affairs.)

d Acceptance of the principles of management has broadened among engineers, executives in industry, and educators.

The second group of factors of progress concerns the application of management methods.

e The engineering or scientific method has extended in industrial cost accounting. Among the developments are uniform cost-accounting systems (Appendix No. 1 to the complete paper lists 64 manufacturers' associations which have adopted such systems), the theory and method of determining and applying standard costs, the methods of determining idleness losses, the forecasting of sales leading to long-term production schedules, and the budgeting of future expenditures.

f Appreciation of the possibilities and advantages of standardization, simplification, and elimination of waste has spread rapidly during the past two years.

g The demand for knowledge, facts, as a basis for judgment has grown insistent in all good management. This has led, among other developments, to a widespread use of specifications and graphics as a means of recording and communicating management knowledge. (The first modern book on graphics in the English language was published as recently as 1910. The Gantt-type control chart has been developed into its present form since 1917.)

h Management methods have been applied or installed in practically every manufacturing industry, in distributing concerns and in institutions. (The report of 1912 listed 52 industries in which some form of management had been installed. A similar list prepared in 1922 would group all the branches of American industry.)

The third and final group of these factors concerns especially significant developments, which after being stated are subject to explanation and comment.)

i Management activities have broadened far beyond the installation of those mechanisms which are usually associated with the Taylor System, and which were emphasized in the report of 1912. (Appendix No. 2 to the complete paper lists 77 items of management work arranged under four headings: General, Labor, Material, Equipment.)

j Some eight or ten of the leading American engineering schools have established courses in management since 1912.

k Appreciation of the importance of the human factor in industry and attempts at its study from a fact basis have been the most striking management development.

l Management engineers have declared that the service motive must prevail in industry and that all questions concerning human relationships must be considered in a spirit devoid of arbitrariness or autocratic feeling.

Management Mechanisms

To secure information as to the use of management mechanisms the question was asked, "What (if any) mechanisms of management do you consider as generally accepted (*a*) in principle, (*b*) in practice?" From correspondents' replies the following twelve quotations have been selected.

> I do not believe that any of the mechanisms of management are generally accepted in principle or in practice.

> I know also that even where some of these things (mechanisms of management) have been established and we hear about them and might conclude that the firm using one or more of them is quite advanced, it often is not at all so. The feature described is only an unrelated "stunt," not supported

by a complete coördinated system of administration and usually begins to go to pieces not long after it is installed.

There is at the present time a retrograde movement in regard to the building up of stores and making operation studies However, as I see it, this is merely a temporary depression in the curve, and I believe that the general tendency of this curve is upward with a very slow ascending grade.

Incentive wage-payment plans have had a temporary setback due to labor conditions caused by the war and to the reluctance of managers in general to consider such plans in any other light but of profit to the company. I do not think that the main service which the incentive plan can give—namely, that of stabilizing relations between employers and employees—has been given sufficient attention by the management.

I believe that such mechanisms as balance of stores, routing, operation, studies, incentive wage plans, personnel work, etc., are generally accepted in principle, but that efforts to install them frequently (perhaps most of the time) miscarry, and either accomplish little or no good. This is often due to a failure to see to it that details connected with the mechanisms are fully understood and looked after.

In a general way, the mechanisms of management are widely accepted now in principle and much less widely in practice.

Undoubtedly, good storeskeeping is becoming very generally accepted. We know that unless we keep accurate records of the materials used we cannot get the most satisfactory results I think storeskeeping is accepted both in principle and practice as well as the intelligent study of operations.

I believe that balance of stores is accepted in principle and in practice, that is, in so far as a written record of quantities in stores is kept in the office rather than in a storesroom, and that a minimum or order point is predetermined and an order placed when it is reached. It is generally accepted in principle, though not in fact, that an incentive wage-payment plan is desirable and effective. It is accepted in principle that facts are shown on charts better than in tables of figures.

In principle, undoubtedly, all of the main mechanisms of management have been thoroughly established.

In a great measure all of the mechanisms of management as developed by Taylor and his immediate associates have been generally accepted in principle. But while they are being widely applied, my impression is that in great majority of the cases the application is half-baked in character and the results, while they may be satisfactory to the companies concerned, are far from being so satisfactory as they should be, either to the management or to the employees. My experience indicates that in most such cases an application such as Taylor would have approved will almost invariably result in increased production ranging from 30 to 100 per cent or more, depending on the nature of the business.

The following management mechanisms have been accepted in varying degrees:

Stores Control. In principle and practice very generally.

Operation Standardization. (*a*) In technical aspects, generally in principle, fairly so in practice. (*b*) In personal aspects, fairly accepted in principle, to a limited extent in practice. [By (*a*) I mean speeds, feeds, equipment, tools, etc.; by (*b*) motion and time studies of human elements.]

Wage-Payment Incentives. Generally in principle and in practice so far as direct labor is concerned. But little application has been made to indirect labor.

Cost Accounting. Generally accepted both in principle and practice.

Selection and Training of Employees. Fairly well accepted as to principle, but little in practice.

Purchasing Control. Generally as to both principle and practice.

Scheduling and Planning. Fairly well accepted in principle. Limited in practice in some industries, well established in others.

I find mechanisms being accepted one by one without a full realization of the part they are to play in the scheme as a whole. That is to say, I will find a company suddenly appreciative of the value of operation studies. It will thereupon proceed to organize to make operation studies, and for the time being in its new enthusiasm it pursues what threatens to become a hobby rather than a part of its business. This pursuit at times leads into the installation of other mechanisms. It begins to recognize, from the operation studies, that a balance of stores is essential, and that a wage incentive is desirable. I find, however, that this progress is accidental rather than planned.

Mechanisms of management such as are discussed in the 1912 Report are generally accepted in principle, but poorly carried out in practice in the majority of establishments. On the other hand, few, representing the best organizations, have developed these things to a degree which serve as valuable guides.

Planning and control are used more and more extensively in plan operation. The tendency of the majority, however, is to try to gain the benefits of more intensive control through partial makeshifts which record past accomplishments instead of actually planning the work. The importance of control, in fact, in increasing production through elimination of idle time, men, and machinery, is not yet recognized except in a few markedly successful establishments. The developments along these lines are being undertaken frequently through inexperienced, low-grade men, who adopt mechanisms as such, instead of developing existing methods on fundamental principles.

Balance of stores is accepted almost universally in principle and widely used in practice. Accountants have been quick to recognize its advantages, and have made it an essential part of their accounting mechanism. On the other hand, two of the most vital features for assisting in the control of production, the column of "stores apportioned" and the entering of "minimum" quantities of each item permissible, are apt to be omitted.

The development of time study and job analysis, while widespread, has been unsatisfactory; piece rates are more and more universal, but their determination is still largely on a basis of past performance, aided by time studies which simply record these performances in more detail instead of analyzing the operations and determining the methods and units which will give most satisfactory results. There is still lack of appreciation of the fact that the chief aims of time study and job analysis must be:

a To resolve the operations into such units that they can be recombined to provide for all variables;

b To take advantage of this unit study to eliminate unnecessary operations, substitute improved methods, and remove defects in equipment and in control.

c To enable the workman to earn more money often with less effort; and,

d To indicate means for improvement in quality and practicable methods for making the improved quality routine.

To these statements of the acceptance of management mechanisms it is possible to add a few quantitative facts. It will be recalled that the field reports of six industries, given in the Report of the Committee on the Elimination of Waste in Industry of the Federated American Engineering Societies, were based on an extensive questionnaire. The replies in four of these industries—metal trades, boot and shoe manufacturing, men's ready-to-wear clothing manufacturing, and printing—have been studied to show the use of mechanisms of management. The facts brought forth are presented in six tables included in the complete paper, of which the accompanying Table 1 is a summary. The questions from whose replies the facts were drawn are given in Appendix No. 3 to the complete paper.

TABLE 1 SUMMARY FOR 51 PLANTS IN 4 INDUSTRIES

Mechanisms of Management	Boot & Shoe, 8 plants			Men's R. M. Clothing, 9 plants			Printing, 6 plants			Metal Trades, 28 plants			Totals, 51 plants		
	None	Inadequate	Good	None	Inadequate	Good	None	Inadequate	Good	None	Inadequate	Good	None	Inadequate	Good
1 Selection and Placement	0	6	2	0	4	5	0	5	1	[1]0_0	6_4	10_8	0	25	26
2 Incentive Wage Plan	0	0	8	4	2	3	1	1	4	2_1	6_3	8_8	8	12	31
3 Planning Centralized	4	0	4	4	2	3	3	2	1	3_1	8_2	5_9	15	14	22
(*a*) Routing, order of work	4	1	3	4	2	3	5	0	1	5_2	6_2	5_8	20	11	20
(*b*) Scheduling, machine assignments	3	3	2	3	2	4	3	2	1	4_1	5_3	7_8	14	15	22
4 Time Study	5	2	1	3	3	3	5	0	1	6_2	2_1	8_9	21	8	22
5 Cost Control	1	3	4	2	5	2	3	2	1	4_2	3_6	9_4 1	12	19	20
6 Idle-Time Analysis:															
(*a*) Men	7	1	0	6	3	0	5	0	1	13_8	0_0	3_4	39	4	8
(*b*) Machines	7	1	0	8	1	0	3	0	3	9_6	1_0	6_6	33	3	15
7 Purchase Control	1	4	3	3	1	5	3	2	1	3_1	4_1	9_{10}	11	12	28
8 Balance of Stores	1	1	6	3	1	5	4	1	1	2_1	4_1	10_{10}	11	8	32

[1] The two figures shown separately in the metal-trades columns represent totals for the 16 plants (upper figure) covered by the regular questionnaire, and the plants (lower figure) which filled out only a condensed questionnaire.

Turning to Table 1 and arranging the eight mechanisms in the order of the number of plants in which they are installed *in some form*, we have:

1 Selection and Placement
2 Incentive Wage Plan
3 Balance of Stores
4 Purchase Control
5 Cost Control
6 Planning (routing, scheduling)
7 Time Study
8 Idle-Time Analysis.

Rearranging in the order of the number of plants where the installation is *good*, we have:

1 Balance of Stores
2 Incentive Wage Plan
3 Purchase Control
4 Selection and Placement
5 Planning (routing, scheduling)
6 Time Study
7 Cost Control
8 Idle-Time Analysis.

The weight of opinion and fact brings the conclusion that certain mechanisms of management have made decided headway in acceptance both in principle and practice, and form an assay of four industries the importance of application yields two groups:

a Balance of Stores
Incentive Wage Plan
Purchase Control
Selection and Placement

b Cost Control
Idle-Time Analysis
Planning
Time Study.

In the installation of such mechanisms a significant change is becoming evident. In early days of management the mechan-

isms concerned the physical means of production. They were originated by the executives and were ordered into the shop.

At a later date, as emphasized in the report of 1912, the value of methods which concerned the worker was appreciated. Training was the first to have any widespread trial. But the attitude was still the developing or forcing of a mechanism from the top downward.

Within the decade under review, another attitude has been adopted in a few instances. It seeks to make the foremen and even the workers consciously parties to the development of the plan before they are put into effect. It endeavors to arouse interest, to inspire to achievement, to release creative energy. Its effect is to install methods and mechanisms from the bottom upward with celerity and improvement in personnel relations.

Management Education of Engineering Grade

Where there was probably but a single college course in management in 1912, there are now eight, in these institutions:

Columbia University
Massachusetts Institute of Technology
New York University
Pennsylvania State College
Purdue University
University of Kansas
University of Pittsburgh
Yale University—Sheffield Scientific School.

The subjects in these courses are given in a fourth appendix to the complete paper. In addition to this form of instruction, management subjects have been introduced in mechanical-engineering courses. Examples are the pioneer work at Cornell University—Sibley College, and at the Worcester Polytechnic Institute.

The growing importance of this branch of engineering education is shown by the number of men enrolled. An appendix to the complete paper (No. 5) gives the enrollment of all students in colleges of engineering in the United States for the school year 1921–1922. The total is 53,414. The number in management courses is 1123, identified as—

Administration Engineering	725
Industrial Engineering	389
Industrial Management	9
Total	1123

The 277 students in "Commercial Engineering" courses have not been included, although they undoubtedly received some instruction in management subjects.

While these management courses in the beginning were based on mechanical engineering their character seems to be changing, so that it can now be said that they are based on engineering broadly, with emphasis on fundamental subjects. There is a tendency to lessen or limit qualitative instruction in details of production. Without doubt, the character of the instruction is improving as teachers gain a wider and sounder experience in the application of management principles.

The significance of this new branch of engineering education is not its extent as measured in numbers of students, but in the fact that at least eight leading institutions have added it to their regular and older courses.

It is unfortunate that no common name has been adopted for these courses; at least four are in use.

The Human Factor in Industry

The report of 1912 presented the human factor in industry with particular emphasis on the responsibility of managers and executive to train their workers and the same thought was prominent in the discussion. According to the comment of the Committee in its closure, one of the striking characteristics which had already gripped attention was "the presence throughout the discussion of a human spirit in keeping with the best trend of thought toward social justice," and "the development that has taken place within the last few years leading to a new appreciation of the needs and rights of employees."

Henry P. Kendall in his discussion of the report[1] outlined the operation of an employment department which he had initiated. The employment man interviewed applicants, selected workers by tests, placed them in positions for which they were fitted, required medical examinations, kept records of each employee, kept in touch with the foremen in regard to the deportment, skill and earning power of the employees, had charge of discipline and discharge, and gave advice, suggestions, and sympathy to the workers throughout the organization.

These disclosures in outline foreshadowed a great wave of industrial relations work which swept through American industry after the outbreak of war. The movement received its impetus from the demand for workers in a time of extreme shortage, and was influenced by emotionalism and social theory. With the return of a labor surplus in 1921 the unsound features have in the main disappeared, leaving but vestiges of the methods and devices which were initiated in such profusion.

The present situation as regards personnel work is appreciation that personnel problems exist, recognition that their solution is a responsibility of management, and a growing realization that job analysis, selection, placement, and training can be put on a scientific basis.

Associated in thought, though not necessarily a part of any employment or industrial relations plan, is the rise of works councils in American industry. Several hundred have been established during the past decade. In August, 1919, there were 225, in February, 1922, approximately, 725.[1] Their development has been in response to a desire on the part of the workers for a means of expressing their beliefs and wishes in regard to matters arising in employment, and on the part of the management for a means of communicating with their employees and gaining and holding their confidence and good will. The movement but emphasizes the fact that the development of the relationships of employer and employed is a responsibility of management.

The Service Motive

Management engineers as a group have declared that the service motive must prevail in industry, that everything planned and done must be directed to securing the worthy result of producing useful goods with a minimum expenditure of time, material, and human effort. One of the clearest statements was written by Henry L. Gantt a few weeks before his death.[2]

> We have proved in many places that the doctrine of service which has been preached in the churches as religion is not only good economics and eminently practical, but because of the increased production of goods obtained by it, promises to lead us safely through the maze of confusion into which we seem to be headed, and to give us that industrial democracy which alone can afford a basis for industrial peace.

This disinterested purpose has been accepted as an ideal for the entire engineering profession, by becoming the challenging thought in the preamble to the constitution of the Federated American Engineering Societies.

To the factors dealing with the steps in the progress of management which have been discussed, should be added a consideration of the extension and growth of management societies which has taken place during the past ten years.

The earliest was the Society for the Promotion of Scientific Management, founded informally in 1910 and organized in 1912. In 1916 the name was changed to the Taylor Society, and in 1918 it was reorganized. Appendix No. 6 to the complete paper gives details of the growth of this society.

The first national organization to deal with personnel matters beginning with the training of workers was the National Association of Corporation Schools, founded in 1913. By 1917 its work had broadened to include all of the activities classified as human relations. In 1920 the name was changed to the National Association of Corporation Training. In May, 1922, it was merged into the National Personnel Association. See Appendices Nos. 7 and 11 to the complete paper outlining the different steps in the development of this society.

In May, 1917, in response to a war demand, The Society of Industrial Engineers was founded. In 1919, it was functionalized and has carried on the activities of a professional engineering so-

[2] Organizing for Work, p. 101.

ciety. See Appendix No. 8 to the complete paper. This Appendix describes the formation of the society.

A second personnel society was organized during the war, May, 1918, under the name of the National Association of Employment Managers. On March 1, 1920, the name was changed to The Industrial Relations Association of America. May of that year registered the peak of the movement, the Chicago National Convention being attended by 5000 persons. The change in business conditions affected it adversely and in December, 1921, the Board of Directors voted to disband the organization. Early in 1922 it was merged into the National Personnel Association. See Appendices Nos. 9 and 11 to the complete paper for details of the growth of this association.

Although The American Society of Mechanical Engineers provided the forum for the presentation of the earliest papers on management, no part of that society was particularly devoted to management matters until the formation of Professional Divisions in 1920. In July of that year, the Management Division was organized. It soon led all of the other Professional Divisions in membership and has held that position ever since. Appendix No. 10 to the complete paper defines management and sets forth the purposes of this division.

There are, therefore, four societies concerned with management—three in its engineering to technical aspects, and one restricted to personnel matters. The combined membership, not discarding duplications known to exist, is 4041.

Management Division A.S.M.E.	1,740
Society of Industrial Engineers	1,032
The Taylor Society	769
National Personnel Association[1]	500
Total	4,041

This membership is growing rapidly; more than one-half has been gained during the past two years for that period spans the founding and growth of the management division of The American Society of Mechanical Engineers.

Within the last two years joint activities have been originated among these and other societies with the promise of benefits to all who are concerned with management. Included are: Development of a management terminology; development of a classification for management literature; standardization of management graphics; and development of methods for the measurement of management.

Management Results

The report of 1912 stated that the results of good management had been: "A reduced cost of product, greater promptness in delivery with the ability to set and meet dates of shipment; a greater output per worker per day with increased wages; and an improvement in the contentment of the workers." There was no evidence at that time that goods had been reduced in price to the consumer.

To a degree this evidence has now been supplied. There are examples where good management has held down prices during a period of inflation and reduced prices as soon as business conditions changed. These acts benefited the consumer. Therefore the management movement can be said to have earned its economic justification.

Management as developed through a generation of effort stands today as a great body of knowledge and practice, to facilitate the operation of industry and the conduct of business. Through organization it determines policies, plans basically over long periods of time and fixes impersonal relationships; through preparation it plans in detail how, when, and by whom work is to be done; through direction it initiates and maintains the processes of production and distribution.

Here, then, is a tremendous, hitherto unknown engineering tool. What is it for? The answer is a spur to every engineer and industrial executive:

Industry and business as developed in modern civilization must continue else infinite misery will overtake the human race. Management is the agency by which community, state, and nation shall endure.

---

[1] The National Personnel Association also has 129 company members.

DEVELOPMENT OF MANAGEMENT IN THE UNITED KINGDOM

By JAMES F. WHITEFORD,[1] LONDON, ENGLAND

IN GENERAL, it may be stated that management practices in the United Kingdom are following very closely the same sequence of developments that has been instituted in American industries. The application is a few years late, but the best portion of the practices in American industries are being fairly generally accepted.

Standardization. The most important development in this country during the past ten years has been a general acceptance of the principle of standardization. One instance will serve as an illustration. Ten years ago one prominent automobile manufacturer supplied his customers with 26 different designs of cars. Today his main advertisement consists of, "This is the only design we make." A manufacturer of food products who had over 3000 lines in his price list ten years ago, now manages to supply the needs of his customers with 215, which includes several packings of the same article.

Specialization. Concentration has become very evident in respect of personnel as well as in the nature of the product, and more and more the individuals of each organization devote their whole attention to certain definite functions the scope of which is more and more limited. Employment of personnel, planning of work, centralized control through statistics, and greater attention to welfare of the employees are the noticeable features in present-day industrial works in this country. This is merely repeating the experience again in American industries.

Employee Representation. Very great advances have been made in British industries in providing opportunity for the employees to participate in the management of the industries. This is particularly true in respect of matters pertaining to working conditions, discipline, and methods of wage payment. In some factories the Whitley Council idea has been adopted in part, the council representing the actual participation of fully 10 per cent of the total employees engaged, but the form of participation varies in each factory.

In general, the Whitley Council as originally promulgated has not been accepted. The ultimate objective was the complete control of each industry by employers and employed, the whole country to be organized under the control of one council. The general and district councils were designed to provide joint management of the industry, deciding all questions of policy and other matters pertaining to the general welfare of the business, which plan was, in my opinion, unsound in principle, since it made no provision to include the buying public. The partial participation in the management has, however, been effected through this medium although one large labor union, the Amalgamated Society of Engineers, refused from the start to sanction the idea or support the movement in any form. The general results obtained are, however, sufficient to warrant the statement that employees' representation is in general use for dealing with matters pertaining to discipline and conditions of employment. It is doubtful if there will be any great extension of duties.

Costs and Statistics. Extensive development has become evident in British industries in respect of improvements in methods of costing, and in providing works statistics for the guidance of the management. In costing work the British manufacturers have not gone into the extensive detail which characterized the installation in American industries, but have contented themselves with providing for the main principles in this branch of factory accounting.

Buildings and Equipment. The new factory buildings are ample evidence of the fact that provision of suitable working conditions and ample supply of light and effective ventilation are accepted as being very necessary in all factories, and provide a distinct contrast with the older buildings in this respect. Up-to-date machinery is also evidence, all of which indicates a new phase in the management of industries in this country.

Welfare. Canteens, playing fields, various forms of recreation, and other matters of similar purport are now receiving a great

---

[1] Industrial Engineer. Mem. Am.Soc.M.E.

deal of attention in all branches of British industries. These are now regarded as very necessary supplements to the ordinary factory buildings and equipment. In many factories rest periods are in use, and in certain of these provision is also made for providing liquid refreshments during those periods. On the whole, there is every evidence that the industrial executives have realized the necessity for providing for the general improvement in the welfare, in working conditions, of their employees.

Wage Payment. Many forms of wage systems are in use, but straight piece work still predominates. Government regulations provide that all employees on differential wage systems shall be provided with data enabling them readily to calculate their earnings. This is probably one of the main reasons why piece work continues to be used extensively. The trades unions in the engineering, printing, and allied trades refuse to accept any form of differential wage plan.

Time Study. The employment of the stop watch in the development of wage-payment standards is being adopted gradually. Its use is still considerably behind American practice, but it is now being generally recognized that basic data are necessary for planning work as well as for wage-payment purposes.

THE DEVELOPMENT OF SCIENTIFIC INDUSTRIAL ORGANIZATION IN GERMANY[1]

BY G. SCHLESINGER,[2] CHARLOTTENBURG, GERMANY

SCIENTIFIC organization in Germany has developed only within the last twenty years. Before that time practical and far-sighted men had sought to adapt the old workshop organization to the rapidly growing industrial works; the engineer devoting his attention to plant and equipment; and the manager occupying himself with questions of bookkeeping and shop accounting. But it was all done without coördination and without system.

Then it came about that the heads of the sales and technical departments of a leading firm of machine-tool builders (Ludwig Loewe & Co., Inc., Berlin) decided to coöperate, with the result that an organization was developed in this establishment that was far superior to that of any other industrial works. Later the head manager of the firm made what was for those times an extraordinary decision: he consented, in the interests of industrial progress in his country, to publish an account of the organization which had been built up in the course of six years. This publication made a deep impression on the industrial and scientific world.

Factory organizations can plan their layout and equipment, their working program, and their cost accounting. In this paper it is proposed to deal principally with cost accounting.

The plan of the accounting system employed by the Loewe Company is briefly as follows:

The factory costs as shown by the "general accounting department" were distributed over the different working departments through the medium of a "shop-record department." The combination of these two departments formed an account which in the general accounting department was called the "shop-record account" and in the shop-record department, the "central account." The distribution was very carefully conducted. A check-up would determine whether everything had been properly distributed. As regarded the shops, the quota would be determined by charging them pro rata to the wages of the workmen. The shops and branches had differentiated (proportionate) charges of the wages.

In a workshop manufacturing only standard parts, partly with very simple and cheap, partly with very complicated and expansive machines, separate costs (known as "place costs") were determined for the various working centers.

At the same time Sperlich published a work in which he recommended that the ordinary simple, flat addition for overhead be replaced by one to be determined separately for each production unit.

Soon after this, the Danish authority West and W. H. Bach of Germany adapted American improvements to German conditions, and later certain large industrial concerns engaged American experts to reorganize their plants in order to introduce American organization methods; but this did not go far beyond the experimental stage.

The only important publication at this time which deserves special mention and which is in a way a connecting link between the old empirical and the new scientific periods, is the work of H. Peiser, business manager of the Berlin-Anhalt Machine Works, Berlin-Dessau, published in 1919, in which a much closer connection is developed between the shop and general accounting department than obtained with Ludwig Loewe & Co.

PROGRESS THROUGH THEORETICAL INVESTIGATION

When one takes into consideration the scientific trend of the German mind, it is not surprising that real progress has been made in this field through theoretical investigation. This progress is due to the work of Dr. Johann Fried. Schär, formerly professor at the Academy of Commerce of Berlin, and founder of modern commercial science.

Schär's idea of the future of factory accuntancy was made very clear to the initiated in his standard work, Bookkeeping and Balance, which has now reached its fifth edition.

In this work he deals, not with planning or management, but with capital, with which the very bases of factory organization are created. "Costs" are not calculated, but the factory capital or assets, the circulation of which is closely followed throughout the work. With a proper accounting system it should be possible to have the assets constantly under control through the monthly intermediate balance *without* inventory.

Schmalenbach, a pupil of Schär's, corrected a fault in the latter's system which made itself particularly apparent in the post-war period. It is this same fault which Gantt scores in his book Organizing for Work, and which he claims exists in some of the most progressive American industrial plants. Schmalenbach in his theory of "*dynamic balance*" recommends the separation of the cost accounting from Schär's capital accounting, which is objective and static. Gantt proposes to consider only those factors in a cost-accounting system which are directly concerned with production. Both are opposed to a distribution of the costs, with which the bookkeeping is burdened. Both wish to obtain the net costs of products constructively. The author does not know whether Gantt ever solved this problem. There is nothing to that effect in the above-mentioned book. At any rate he has read or heard nothing of the carrying out of the theories of Schär and Schmalenbach; but has found them applied in the practical work of Ernst Just and Elizabeth Vöhl, with whom he coöperated during four years and whose work will now be described in detail.

THE WORK OF JUST AND VOHL

The progress of these two is based on philosophical principles and practical experiments, which latter were conducted in about 600 small industrial plants in twelve different branches of industry. The result was the Hansa accounting system with its four successive stages. With this completed they consulted Schär, who gave them the benefit of his wide knowledge of accounting and organization problems. His theoretical conclusions agreed with the practical results they had obtained and helped greatly in the explanation of these complicated problems.

Then followed twelve years of practical work in large and medium size factories representing all branches of industry. The author has been specially privileged in being made acquainted with the results of this work and he is convinced that industrial plants could be operated with far greater success if they would adopt this system of organization.

Just starts with a search for objective measures which will serve as a substitute for the "experience and intuition" characterizing present-day methods. The aim of this scientific research is to find the vital law of a manufacturing plant through analysis of its problems and to build it up anew.

In Just's practical mind the scientific requirements of Schär took shape in the following problem: How can what goes on in a factory—the expenditure of capital and the creation of new capital—be actually and ideally presented simultaneously? The problem is therefore this: that every movement of the industrial capital

---

[1] Abridged.

[2] Professor of Engineering, Technische Hochschule. Mem. Am.Soc.M.E.

in its circulation from stationary capital (assets) to journal assets (production costs, overhead) to production assets (products) and back again to stationary capital (stock assets, customers' orders, bank deposits) be once actually and once ideally presented.

Just and Vöhl found the solution of this problem through combining the ideas of Ludwig Loewe, Schär and Schmalenbach, and arranging them into three separate accounts:

1 One for stationary capital = calculation of assets account
2 One for journal assets = shop account
3 One for production assets = products account.

These three accounts are kept according to the principles of double-entry bookkeeping, and are therefore self-controlling.

However, these three accounts are kept separately only during the period of business activity. On closing day—intermediate balance, annual balance—they are combined and become part of the assets account. As they bear a fixed relation to one another and are combined on closing day, they therefore control one another.

Through the clear and systematic arrangement of the component parts of this accounting system, especially the production costs, only one accounting formula is required which, in contrast to former systems (Loewe, Peiser, American) does not charge everything to wages, which is distribution backward, but *builds up* from the bottom and makes its possible to recognize the influence of the separate factors, which was the aim of Gantt.

The author wishes now to discuss briefly the attitude of German industry to the scientific and practical development described.

The work of Just and Vöhl, which has not hitherto been made public and consequently cannot have been discussed, must necessarily be excepted. Unfortunately it must be admitted that leading engineering societies and industrial associations have not only disregarded the treatises of Schär and, to a certain extent, those of Schmalenbach, but have instituted a sort of counter movement with the argument that the work of Schär and his pupils does not meet with undivided approval. At the request of one representative engineering society, The Committee for Economic Production (AwF), a special committee was appointed consisting of twenty members, including engineers, merchants, industrial leaders, economists, scientific and practical experts, for the purpose of seeking out the best of the literature on hand, supplementing and improving it on the basis of their own experiences, drawing conclusions from the whole result, and publishing these as a "standard," somewhat on the order of the standard sheets on allowances, screw threads, pulleys, etc., published by the German Industrial Standards Committee.

This compilation was published in two editions in the years 1920 and 1921, under the title, Basic Scheme of Net Cost Finding, and was sent to all German industries.

It must be admitted that this "basic scheme" represents in no respect an improvement on those of Loewe, Peiser, or the American authorities. This result was to be expected when such difficult problems—probably the most difficult that technical and scientific industrial research have to deal with—are settled by majority conclusions.

GERMAN INDUSTRIAL ATTITUDE

While "practical" America is making every effort to build up a *scientific* system of industrial management, "scientific" Germany is thus returning to purely *practical* experience for guidance in the organization of industrial plants. But not all have taken part in this retrogression, and the author can at the same time report that the same head manager, Waldschmidt, of the Ludw. Loewe factory, who eighteen years ago permitted the epoch-making description of his work to be published, recently requested the practical research workers, Just and Vöhl, to discuss the basic principles of their work for the benefit of German industry at the Research Society for Scientific Management over which he presides. After two introductory addresses which were presented in April, 1922, Just and Vöhl, at the request of the above-mentioned society, prepared seven theses, in which they present their views of the factory-accounting methods now in vogue. Five distinguished professors of engineering and commercial science (Schär, Schmalenbach, Schilling, Schlesinger, and Wallichs) will take the opposite side in a debate to be held before the board of directors of the society on September 14 of this year, and it is hoped that this discussion will serve to bring about a radical change in works organization in Germany.

The theses are as follows:

SEVEN THESES FOR DISCUSSION

I—It is *wrong* to place shop accounting in charge of the separate departments in such a way that a sales-accounting system is conducted under the sales manager, a shop-accounting system under the shop manager, etc. It is *right* to establish a uniform system of shop-accounting with a position within the administration corresponding to the following scheme:

a Management
b Work
  1 Outside work
  2 Inside work
c Auditing

The auditing should therefore be independent of the work, and both should supply the management with means with which to control the work.

II—It is *wrong* to attempt to bring about the necessary unity in accounting by forcing it into *one* accounting system (mingling assets, operating and sales accounts indiscriminately together). It is *right* to build up a unit system of accounting consisting of three divisions, which can be balanced separately during work. These divisions are:

1 Calculation of the stationary capital: *Calculation of assets.*
2 Calculation of capital used in factory operation: *Operating Capital.*
3 Calculation of capital gained from products: *Production assets.* On periodical closing days they must be combined.

III—It is *wrong* to build up an accounting system partly on a systematic and partly on an unsystematic basis as is usually the case. For instance:

1 Calculation of stationary capital systematically, according to principle of double-entry bookkeeping
2 Shop calculation unsystematically, as single-entry
3 Production calculation also as single-entry.

It is *right* to conduct the whole accounting system according to the principles of double-entry bookkeeping.

IV—It is *wrong* to determine the relation between (*a*) capital and production accounting and (*b*) capital and stock accounting in such a way that one must specifically explain the other. It is *right* to establish the inter relation of the three accounts similar to that between seller and purchaser as follows:

1 Determination of overhead: Seller or contractor is capital accounting, purchaser is shop accounting
2 Calculation of material and labor: Contractor is capital accounting, purchaser is production accounting
3 Calculation of shop costs: Contractor is shop accounting, purchaser is production accounting
4 Calculation of finished products: Contractor is production accounting, purchaser is capital accounting
5 Closing calculation (annual balance or monthly intermediate balance): Contractors are shop and production accounting, purchaser is capital accounting.

V—It is *wrong* to organize the accounting system in such a way that it computes (1) too late, (2) too seldom and (3) only with the aid of an inventory of (*a*) the assets and (*b*) the results. It is *right* to conduct the accounting in such a way that this information is obtained (1) during production of work, (2) once a month, and (3) automatically.

VI—It is *wrong* to determine the net cost value of products by means of calculation (by auditing). It is *right* to determine the net costs by means of accounts (so-called record-keeping) conducted on the principles of double-entry bookkeeping and which keep pace with production progress.

VII—It is *wrong* for different concerns in the same branch of industry to have separate systems of accounting, so that comparisons with regard to the elements of net costs cannot be made between them, and consequently agreements with workers, government authorities and trade competitors cannot be made on a known basis. It is *right* that every industrial association should require its members to adopt a uniform system of accounting to the end that intelligent comparison may be made.

The author, however, is witness to the fact that these theses present only conclusions from the practical work that these two have successfully carried out in the most widely different branches of industrial work. Besides their fundamental ideas, they have also developed working rules, methods and means for putting these ideas into practice.

In conclusion, the author would say that it gives him great pleasure to be able to acquaint the American industrial world with the results of scientific and practical industrial organization in Germany. He is convinced that after a long period of lagging behind, his countrymen have now caught up with Americans in scientific management. However, the deeper foundation that they possess and the greater economy of operating their system (they can carry out the work of accounting in factories according to their method with half the personnel that is required with the usual American system), will perhaps prompt American industry to take note of their organization, science and practice, as German industry once gladly and gratefully accepted advice and information from American sources.

The Commercial Economy of High Pressure and High Superheat in the Central Station

By GEO. A. ORROK,[1] NEW YORK, N. Y.

IN THIS AGE of progress when the designers of central stations of all types and kinds are vying with each other in the use of higher pressures and temperatures as well as multiplying the complication of the steam generator, prime mover, and auxiliaries, it is expedient to go back to the beginnings of the central station and by a review of the line of development get a broad perspective of the field of power generation which will enable us to apply, to the newer developments, those basic principles of commercial economy and efficiency necessary to a proper solution of the problem.

The earlier use of steam when its expansive force had not been discovered, is best shown by the Newcomen pumping installations, in which the steam was used at atmospheric pressure. Watt discovered the expansive force of steam and so improved the boiler, engine, and steam piping that 15 lb. gage could be used economically. From his time until about 1900 rising pressure kept pace with improvements in materials and in the design and construction of steam generators and piping, with occasional excursions into the realms of higher pressure and temperature. Practice at this date (1900) may best be illustrated by the work of the Wildwood engine. Since 1900 improvements in steam generators, piping, and prime movers have been made with increasing rapidity, and many modern plants are running on 250 lb. and 200 deg. of superheat, using standard piping and valves with the newer designs of boilers, superheaters, and turbines. Table 1 shows the pressures and economies theoretically possible and attained in a central station, with all the results reduced to British thermal units in the coal per kilowatt-hour of useful work.

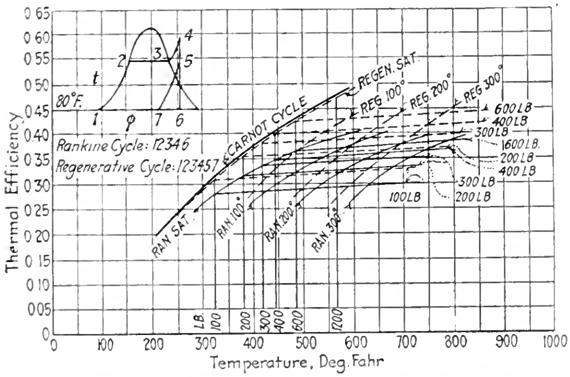

FIG. 1 THEORETICAL THERMAL EFFICIENCY OF THE CARNOT CYCLE, THE RANKINE CYCLE, AND A REGENERATIVE CYCLE, USING BOTH SATURATED AND SUPERHEAT VALUES FOR RANGES UP TO 1200 LB. AND SUPERHEATS OF 750 DEG. AND ABOVE

TABLE 1 STEAM PRESSURES AND ECONOMIES THEORETICALLY POSSIBLE AND ACTUALLY ATTAINED IN CENTRAL STATIONS

Year	Engine	Pressure, lb. per sq. in.	Temperature, deg. fahr.	Thermal efficiency, Carnot cycle, per cent	Actual B.t.u. per kw-hr.	Actual overall thermal efficiency, per cent
1770	Newcomen	15	212	2.7	416,000	0.82
1810	Watt ..	30	300	9.17	61,000	5 6
1900	Wildwood	215	400	20.8	19,200	17 75
1922	Modern	265	650	35 00	18,000	19.00

Our engineers are now using better and more uniform materials than ever before. Our metallurgical and manufacturing methods have been greatly improved. Copper, wrought iron, and cast iron have been discarded for boiler purposes. Steel and even alloy steel are in common use and their uniformity leaves little to be desired. Certain of the non-ferrous alloys are in common use and play their part in aiding the common security which characterizes modern installations. Copper boilers and 212 deg. maximum temperature gave place to wrought-iron boilers and 30 to 40 lb. pressure with a maximum temperature of 300 deg. The use of steel as a boiler material raised the pressure to 200 lb. and the temperature to 400 deg., while our modern steels allow pressures up to 400 lb. with a maximum temperature of 750 deg. In certain distillation plants temperatures as high as 1100 deg. have been obtained, but the life of the material is short.

Now it is well known that steel when heated to comparatively low temperatures, say, 900 or 1000 deg., loses its strength and becomes unfit to sustain loads, and the heat strains from even moderate heating of 300 or 400 deg. may cause certain deformations of a highly unsatisfactory character. Cast-steel valves have deformed at 750 deg. to such an extent as to render them useless, and the "growth" of ordinary cast iron at temperatures above 450 deg. is known to be destructive; but notwithstanding this the later constructions at 250–300 lb. pressure and 700 deg. maximum temperature are commercial. The first cost is not excessive, repairs are moderate, and the life of the installation is all that can be desired.

COMMERCIAL LIMITS OF PRESSURE AND SUPERHEAT IN THE CENTRAL STATION

What, then, are the commercial limits of pressure and superheat in the central station? In Fig. 1 we have calculated and plotted the theoretical thermal efficiency of the Carnot cycle, the Rankine cycle, and a regenerative cycle, using both saturated and superheat values for ranges up to 1200 lb. and superheats of 750 deg. and above. It will be seen that the chosen regenerative cycle for saturation follows very closely the efficiency of the Carnot cycle, while the Rankine cycle falls below the Carnot cycle increasingly with rise of pressures. The superheat lines for both cycles are nearly parallel and maintain this characteristic over a wide range. The gain from regeneration increases with pressure and is constant for equal superheat. For any final temperature the gain from pressure increments decreases, but the gain from regeneration increases with pressure increments. Thus at 750 deg. final temperature the Rankine efficiency increases from 33.5 per cent to 40.5 per cent with pressure rise from 200 to 1200 lb., while the regenerative efficiency increases from 37 per cent to 48.5 per cent with the same pressure increase.

Fig. 1, dealing with theoretical efficiencies only, does not show the station losses which aggregate around 45 per cent. Grouping the losses, we may say that the generator efficiency is 97 per cent, turbine efficiency 78 per cent, boiler efficiency 80 per cent, leaving for auxiliaries, piping, and radiation 91 per cent, all of which multiplied together give 55 per cent efficiency.

TABLE 2 SAVINGS EFFECTED THROUGH INCREASE IN STEAM PRESSURE

Case	Cycle	Pressure, lb	Max. temp. deg. fahr.	Theoretical efficiency, per cent	Station efficiency, per cent	Actual efficiency, per cent	B.t.u. per kw-hr.
1	Rankine	200	750	33 5	55	18 4	18,500
2	Rankine ..	1200	750	40 5	55	22.3	15,300
	Saving			21			3,200
3	Regenerative.	200	750	37	55	20.35	16,800
4	Regenerative	1200	750	48.5	55	26.7	12,800
	Saving.. ..			33.3			4,000

Table 2 shows how these figures work out for the above suppositions. The saving by regeneration when using 200 lb. pressure (Case 1 – Case 3) is 1700 B.t.u., and when using 1200 lb. pressure (Case 2 – Case 4) is 2500 B.t.u. Considering the trend of the curves in Fig. 1, on this page, comparatively little is gained by further superheating, but there has been no attempt to go above 800 deg. and the flattening out is much more marked as the temperature increases.

---

[1] Consulting Engineer, 17 Battery Place. Mem. Am.Soc.M.E.

For presentation at the Annual Meeting, New York, December 4 to 7, 1922, of THE AMERICAN SOCIETY OF MECHANICAL ENGINEERS. Copies of the paper may be obtained gratis on application. All papers are subject to revision.

Water has its critical temperature at 704 deg. and the critical pressure is about 3200 lb. Pressures up to this limit may therefore be considered, and since oil-still temperatures up to 1100 deg. have been used, we may consider superheat temperatures up to that point. We know that the first allotropic change in steel occurs at about 1300 deg. and 1100 deg. is well below this point. Here, however, we must look into the physical properties of the steels used in power-plant construction.

When steel is heated the first sign of change—a dull red just visible in the dark—appears at about 750 deg. Visibility in daylight begins at about 850 to 900 deg. and a full dark red is attained at about 1100 deg. The full cherry red is attained at the first allotropic change of 1300 deg. Good boiler steels increase in tensile strength up to about 600 to 700 deg. and lose much in ductility, but above 800 deg. the tensile strength rapidly falls off and the ductility largely increases. Cast steels of proper carbon content and suitable for fittings, valves, and turbine construction show the same properties within rather narrow limits. Pipe steels have nearly the same characteristics, but the temperature at which the tensile strength starts to fall is around 550 to 600 deg. This lack of ductility or increase of brittleness at the maximum temperature of use must be compensated for by a larger factor of safety (i.e., increased thickness and weight with higher cost) and a more careful selection of material. But with increased thickness it must not be forgotten that the safe stresses must be correspondingly lowered. The variation of strength of materials with temperature is covered in an appendix to the complete paper.

Variation of Strength of Materials with Temperature

This subject may be considered from five points of view, depending on the conditions under which the materials are to be used.

(a) *Boiler Material.* Here we know that the maximum temperature cannot exceed 704 deg., the critical temperature of water, and that the fire side of the tube or drum can only be a few degrees hotter. If 1200 to 1800 lb. per sq. in. be the chosen pressure, the water temperature is 625 deg. at maximum and the fire side will not exceed 725 deg. normally. This temperature is well within the maximum-strength zone, and only care is needed to secure sufficient ductility.

(b) *Superheater Material.* The maximum temperature of the inner surface of the tubes may be a little higher than the maximum superheat. The outer temperature depends on the position in the boiler. Radiant-heat superheaters are now commercial where the pressure parts are protected with a heat-absorbing and conducting covering of cast iron. The fire surfaces may be 1400 deg. to 1600 deg. while the inner-wall temperature is as low as 700 deg., but 1100 deg. is comparably easy of attainment. Bare-tube superheaters would have a maximum outside temperature of around 1200 deg., but the life at this temperature is unknown. The maximum safe point may be taken as 800 deg. superheat temperature and 950 deg. outside temperature.

Neither the tube manufacturers nor superheater manufacturers are afraid of these conditions, and I believe they are prepared to guarantee their product under such conditions.

(c) *Piping Material.* Under this category the condition is markedly different. The steam side of the pipe is below the maximum temperature of the steam. The outer surface is much lower and the thickness of the material can be increased to compensate for the lower elastic limit of the material. The ductility is improving with temperature increase. Pipe joints are the only serious trouble, and the modified Van Stone joint with the pipe edges welded for tightness is the apparent solution. Experience with this joint has been satisfactory.

(d) *Valves and Fittings.* Valves and fittings must necessarily be made of castings, and the low-carbon, open-hearth steel used, while falling off in strength sooner than the worked material used in boiler and piping, has still a respectable elastic limit at 1100 deg. As in the last category, the inside-wall temperature is lower than the steam temperature, with still lower temperatures at the outer wall. But the shape of the casting is all-important. Globe valves of the double-beat or Wanick type can be made with practically no flat surfaces and with two axes of symmetry. Internal pressures do not seriously deform this design, but external strains may cause minor troubles. Throttle valves and marine stop valves are usually of this type and can be kept tight at 750 deg. It is probable that a temperature of 1100 deg. could be safely undertaken with these valves if special precautions were used in the design of the seat, disk, and stem. Flexible-disk, double-beat valves are used in Europe at temperatures in excess of 750 deg.

Gate valves have only one axis of symmetry and flat surfaces of considerable size. Here seat and disk troubles are encountered at temperatures above 700 deg., and it may be some time before the manufacturers can guarantee a tight job at the higher temperatures. This type of valve is peculiarly sensitive to outside strains tending to deform the seats and disk.

(e) *Turbine High-Pressure Ends.* Pressures can make little difference here as the high-pressure parts are comparatively small and without doubt the pressure will be reduced 50 per cent in the first nozzle. There need be no high-pressure stuffing box, so that the highest pressure to be packed against will be about half the maximum. Temperature strains will be the only thing that need be considered, and the expansion will reduce the superheat in the first-stage nozzle to a workable value, which is 750–850 deg. It is to be noted that steam-chest or nozzle-box troubles have been the only prominent troubles where 400 lb. and 750 deg. superheat have been tried out, and it thus appears that a proper design will obviate most of the trouble. Cast or forged steel must be the material used.

In general, the turbine designers say that 1200–1500 lb. pressure has no terrors for them and can be used when desired. They can supply the apparatus. Temperatures are more troublesome and no one apparently cares to go much above 700–750 deg. at the present time. Superheater and valve materials at present seem to be the deciding factor in the use of high pressures and temperatures, and there is apparently very little which careful design and the selection of proper materials will not overcome.

Only a portion of the central-station installation is affected by high pressures and temperatures, especially where electric auxiliaries are used. The boiler and piping system and prime mover cover the entire list, and in the usual central station this has represented about 40 per cent of the entire installation cost. Latterly, with the larger station the percentage is around 30, and may be taken at 25 per cent for the newer and larger stations of which Hell Gate and Calumet are types. If the station cost be taken at $100.00 per kw. as an average figure this portion of the installation has cost $25.00, and at 15 per cent the fixed charges are $3.75 per year or on 5000 hours' use 0.07 cent per kw-hr. What, then, will be the extra cost of this apparatus when designed for higher pressures and temperatures? Standard boilers today can be bought up to 275 lb. pressure; 300 lb. necessitates thicker plates and tubes, and prices advance accordingly. 400-lb. boilers have been purchased recently and 500-lb. boilers have been built. Flash boilers of the Serpollet and De Laval types using pressures in excess of 1200 lb. and coil boilers of the Herreshoff type using equally high pressures have been built as experiments or in toy sizes as for automobile work or for high-speed launches. Schmidt's water-tube boiler working at 900 lb. has been run 14,000 hours with marked success. Boilers for 400 lb. pressure have been offered at about 50 per cent increase in price and 1200-lb. boilers have been figured at a 100 per cent increase in price.

Turbine designers are at work on designs arranged to utilize higher pressures, but higher temperatures seem more troublesome to them. I have no estimate, but we can safely apply the same percentage increases of price to the turbine that obtain with the boiler. Steam piping decreases in size with increasing pressure, so much so that it is doubtful if a 1200-lb. steam line would cost more than a 200-lb. line of the same capacity. The volume of high-pressure steam at 1100 deg. maximum temperature is quite uncertain, but the chances are that our figures are not more than 10 per cent from the truth.

Summary

We may then summarize as follows:

a Pressures up to 1200–1500 lb. at least are commercial and may be attained without serious difficulty.

b Temperatures for the present are commercial up to 700–750 deg., which should not be exceeded until our materials for valves and superheaters are improved. More extended experience is nec-

essary before the range of 800 deg. and over is attempted in a commercial installation.

c With the completion of the Steam Table Research it will be possible to calculate accurately just where the possible limits of economy in pressure and temperatures may be located. At the present time the uncertainty of all values above 200 lb. pressure and 4000 deg. fahr. temperature render most of our calculations of only academic value.

d There still appears to be more economy in a closer study of operation and construction losses—resulting in improving the efficiency of central stations installed in accordance with the present accepted canons of design—than in the attempt to widely increase the temperature range of our heat cycles. While we may save 400 B.t.u. per kw-hr. by using a regenerative cycle and increasing pressure and temperature, it should be possible to save nearly as much by a reduction to the lowest limits of the heat losses which we know exist in our present installations.

TABLE 3 SAVINGS IN COAL

Savings of Regenerative Cycle

In Table 3 we have given for 700 and 1000 deg. maximum temperature and for four pressures the theoretical efficiency of the three cycles used, the practical efficiency of the Rankine and regenerative cycles, and the savings per kilowatt-hour for all conditions over the Rankine cycle at 200 lb. and 700 deg. maximum temperature in B.t.u. and lb. of coal of 13,800 B.t.u. content.

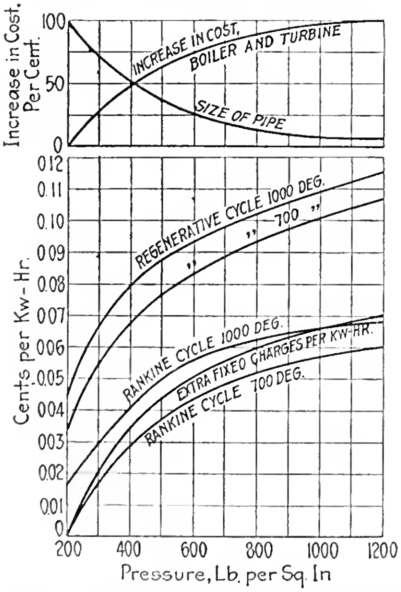

Fig. 2 Savings in Cents per Kilowatt-Hour for All Conditions Over the Rankine Cycle at 200 lb. and 700 Deg. Maximum Temperature, Based on $6.00 Coal

In Fig. 2 these savings are plotted in cents per kilowatt-hour on the basis of $6.00 coal, together with the extra-fixed-charges curve. At the top of the figure are two curves showing the percentage increase in cost of boiler and turbine and the decrease in size of pipe required for a given quantity of steam. It will be seen that the extra fixed charges are always greater than the coal saving for the Rankine cycle (ordinary operation) at 700 deg. maximum temperature, and that the additional gain for the 1000 deg. maximum temperature barely exceeds the additional fixed charges. We cannot then expect much from increasing pressures and the ordinary methods of using steam. Increasing temperatures help to some extent, but not enough to be attractive, since the saving is nearly all used up by the additional fixed charges.

With the regenerative cycle the results are much better and useful savings are indicated, increasing considerably with pressure and slightly with temperature. It is evident that some such regenerative cycle must be used, but the rewards from increasing temperature are not commensurate with the costs. Many regenerative cycles are possible, but the one used shows nearly the maximum economy. Such cycles need many heat interchangers and a number of separate feed pumps for the close approach to theoretical figures. Indeed, Thurston and Stanwood[1] in 1899 pointed out that with an infinity of heaters and pumps the Carnot efficiency might be equaled. So far, however, four or five stages have been the ultimate practical application, and not more than three have stood the commercial test. It would appear that considerably better design must be put in the apparatus if many steps are proposed, and also that more consideration must be given to the operating difficulties.

Acknowledgment

Much of the work in connection with the preparation of this paper has been done by W. S. Morrison and M. A. Guigou, members of the Society. An appendix dealing with the properties of metals at high temperatures and which accompanies the complete paper is the work of Mr. Morrison; most of the calculations have been done by Mr. Guigou and the drawings made by Mr. H. H. Worth, Junior Member Am.Soc.M.E. Credit should also be given to a number of my friends and associates who have criticised the paper during its preparation.

When the plant of the Buffalo General Electric was put into operation in 1916 and 1917, it represented the high-water mark in steam pressures and temperatures in large power-plant practice in this country. This plant attracted international attention, and although at that time it was predicted by some authorities that five hundred or six hundred pounds pressure was a probability of the near future, there are still many large plants that seem to favor pressures of about three hundred pounds and a total temperature of around six hundred degrees. There are a few exceptions, but in the main the operator has not taken kindly to pressures and temperatures much above these, as it has been found one thing to design and construct a plant for high steam pressures and temperatures and an entirely different thing to operate the plant and make it give reliable service. However, many of the earlier operating difficulties have been overcome and, after what might be considered a pause at steam pressures of about three hundred pounds, the tendency is again to go to higher pressures. A notable example of this is the new plant of the Public Service Company of Northern Illinois, at Waukegan. These boilers, which will operate at four hundred pounds pressure, are of a new design especially adapted to high pressures in large units. Although this is the first time that pressures in excess of three hundred fifty pounds have been employed in large plants in this country, marine-type boilers have been built for six hundred pounds but they have been small-sized units. The new boiler is a somewhat radical departure from the standard designs that have been employed in large sizes for stationary work up to three hundred fifty pounds.

An increase in Rankine cycle efficiency is obtained with an increase in pressure up to about eighteen hundred pounds, after which it begins to fall off. However, this increase in efficiency is not in direct proportion to the increase in pressure. With steam at a constant temperature of seven hundred degrees there is a gain of about three and one-half per cent between one hundred fifty and three hundred fifty pounds. From this point the curve begins to flatten out, and the gain between three hundred fifty and six hundred pounds is only two per cent, with an additional gain of two per cent by carrying the pressure up to one thousand pounds.—*Power*, Sept. 12, 1922, p. 424.

The Preservation of Decaying Wood Roofs

General Theory of Wood Decay—Methods Employed in Preserving Wood Roofs Economic Considerations in Prolonging the Useful Life of Repaired Roofs

By WENDELL S. BROWN,[1] PROVIDENCE, R. I.

RAPID development in industry, like the accelerated progress of civilization, is often and perhaps inevitably accompanied by certain afflictions and disorders. And in the last quarter century one of the disturbing conditions which has arisen and which is demanding increasing attention in certain sections of the industrial world has been the serious decay of wood roofs.

Now a roof is a cover of a building, according to one dictionary definition. But unfortunately, since the advent, in buildings of home-made weather, either in the form of artificially high or naturally high relative humidities—due to some necessary process—a roof must have other attributes than covering only, if it is to act as a real shelter. For, under certain conditions instead of constituting a protection, the reverse is true, and the roof becomes a positive source of trouble. This happens when the formation of condensation (commonly called sweating) on the ceiling is so rapid as to cause dripping into the room below, with consequent annoyance to the occupants and often serious damage to machinery, building, and materials in process.

Happily, it is a comparatively simple matter, by adopting suitable insulation, to prevent the formation of condensation on, and dripping from, the under surface of the roof, for any usual condition encountered. That is, theory and laboratory tests, authenticated by actual installations, have provided accurate methods for rationally designing many different types of roofs to meet varying requirements as to relative humidity and temperature carried in the room below.[2]

But with respect to wood roofs, prevention of visible condensation is only part of the story, for the reason that cracks between the plank afford a more or less direct channel by which warm, moist air from the room below reaches the roofing paper, which latter is practically at the temperature of the outside air. If this temperature is below the dewpoint of the said contacting room air, precipitation of moisture or condensation results; which means nothing more nor less than that the first ply of roofing paper and the top of the wood roof itself are saturated with water during the greater part of the heating season in temperate or colder climates. Laboratory tests and the experience of those who have removed old mill roofs bear this out.

In fact, this rot-inducing feature is the outstanding bugbear and cause of excessive mortality in wood roofs of those manufacturing buildings—such as textile mills, finishing plants, paper mills and food factories—which utilize or by nature house high relative humidities. The damage is enormous—greater than generally realized—amounting to hundreds of thousands of dollars annually in building material alone, besides occasioning often more serious losses in production and general derangement. Many such unenviable records exhibit useful roof lives as short as three years, with a possible average of ten years and a maximum of twenty-five years, depending upon the severity of atmospheric conditions within and without the building, and the species and quality of lumber used.

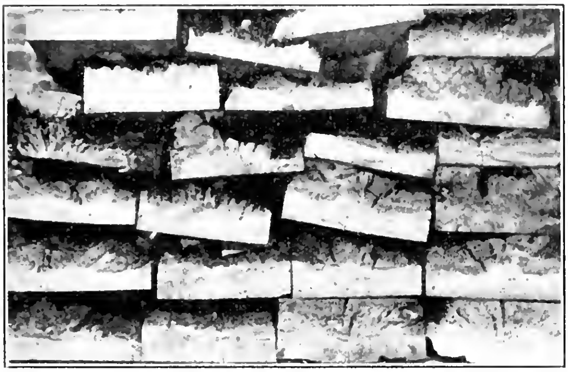
Notwithstanding the subject under consideration is the preservation of old wood roofs, it would be remiss not to admit that some of them are not worth saving. The correct determination of whether or not a roof is worth saving lies in a full consideration of the problem from a purely utilitarian viewpoint, and the paper aims to indicate general principles by which this often debatable question may be settled, and also to describe one method by which the desired result has apparently been attained.

General Theory of Wood Decay

The almost exclusive cause of decay in wood is the destroying action of certain fungi, of which there are several varieties. These, however, in order to accomplish their destructive work, must have a favorable environment, which, in addition to suitable media in the form of wood fiber from which their food supply may be obtained, consists of the proper amount of moisture, temperature and air supply. There are two general classifications of such fungi:

1. The "dry rot" group, thriving in a comparatively narrow range of cool to moderate temperatures and not requiring great amounts of moisture;
2. The "damp rot" or "mill roof" group, thriving over wider and generally warmer temperature ranges, but requiring relatively large amounts of moisture for their normal development.

As indicated in the name, we are concerned particularly with the second group, which requires either air at practically 100 per cent relative humidity or a free supply of water in its liquid state. Incidentally, since air is necessary for fungus growth, the presence of water to such an extent as to prevent admission of air to the wood cells is fatal.



(*Photo by F. J. Hoxie*)

Fig. 1 Showing Typical Decay in Roof Plank Starting at Top Surface

Wood roofs over buildings housing ordinary temperatures and humidities lack only one requirement to make them excellent media for infection and decay from the second group. This one deficiency is moisture, which, in the case of those special roofs under consideration, is supplied by condensation.

There are perhaps half a dozen kinds of fungi most commonly found attacking mill roofs, and the limits of temperature and moisture most favorable to their development vary somewhat with the species. Many investigators, both here and abroad, have devoted considerable study to the classification of fungus diseases, and the conditions affecting their germination, dissemination, and subsequent development and viability. For instance it has been found that the temperature at which most of the mill-roof fungi grow and spread lies between the approximate limits of 35 deg. fahr. and 110 deg. fahr., the optimum limits for development being considerably narrower than the above—approximately 75 deg. fahr. to 100 deg. fahr. Alternate wetting and drying is destructive to the spores cast off by certain fungi; and some varieties develop best in darkness, while others require diffused light, but not direct sunlight.

Ordinarily, decay in roof plank starts at the top surface (see Fig. 1), especially if the first ply of paper is dry sheathing not mopped

---

[1] Engineer, F. P. Sheldon & Son. Mem. Am.Soc.M.E.

[2] See original paper on this subject by F. P. Sheldon & Son, Engineers and Architects, Providence, R. I., entitled Experiments to Determine the Relative Effectiveness of Various Types of Roofs in Preventing the Formation of Condensation upon their Under Surface, read before the National Association of Cotton Manufacturers, 102nd Annual Meeting, Boston, Mass., April 25, 1917.

Presented at the Springfield Regional Meeting of The American Society of Mechanical Engineers, Springfield, Mass., September 25–27, 1922. Slightly abridged.

down. Sometimes, however, infection seems to get a foothold first just above the tongue and groove or spline and progresses more rapidly within the central portion of the plank lying between the two extremes of moisture.

In sawtooth buildings, valley plank usually decay first, this being generally traceable to one or more of the following contributory causes:

a Since sawtooth lighting areas ordinarily face approximately north, the valleys are considerably shaded by adjacent sawteeth, which latter intercept the warming effect of the direct solar rays when the sun is at low altitude during the heating season.

b Often heating coils are located solely under the glass or at some distance up the wooden back of the sawtooth, leaving the valley portion chilled, and subject, therefore, to excessive condensation.

c There is a tendency for moisture or condensation to drain toward the low point of the roof.

An indication of the comparative extent to which rotting has progressed in various portions of a roof may often be had from the brown extractive matter deposited in rusty streaks on rafters and plank. Decay is usually greatest in plank and beams at bearings because, due to the additional insulating properties of the supporting members, the locus of condensation[1] dips as indicated in Fig. 2. Tops of roof rafters and girders rot first—usually for the same reason; and other conditions being equal, decay is more active in the vicinity of ventilators, cold conductor pipes, etc.

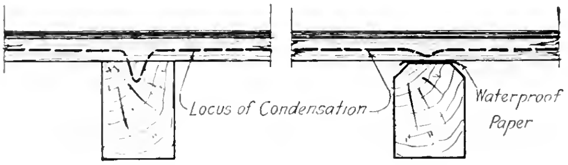


Fig. 2 Fig. 3

Fig. 2 Showing How Locus of Condensation Dips Over a Beam or Rafter

Fig. 3 Showing How Locus of Condensation May be Raised by Chamfering Corners of Beam or Rafter

But the quality of lumber as well as species or variety is also a vital factor in its longevity, and variations in the former often tend to upset too close generalizations concerning the placement of decay. For instance, three years ago two bays of roof plank and one roof rafter in a Rhode Island weave shed were replaced with entirely new but unsuitable material having a high percentage of sap wood. The plank is already more than one-half rotten and is in a worse condition than the remainder of the roof which is thirteen years old.

Methods Employed in Preserving Wood Roofs

Taking up the question of treatment, there seems to be no practicable means of preventing exposure to infection, or of eliminating rot-inducing conditions, as far as temperature alone is concerned.

For new wood roofs antiseptic treatment is possible, and several processes, such as creosoting and kyanizing, may be adopted for the preservation of plank. One creosoting concern has recently introduced a priming paint and claims that it is not penetrable by creosote, thus making possible the application of white ceiling paint directly without sheathing. Girders and beams may be made of steel, but if untreated timber is used the upper edges of beams may be chamfered and covered with a layer of waterproof paper, as shown in Fig. 3. Chamfering tends to raise the locus of condensation, and the paper still further assists in keeping the top of the beams dry.

In the case of existing roofs the treatment must of necessity be ameliorative rather than preventive or curative; and it should be clearly understood that the term "preservation" is meant to indicate merely the economic postponement of ultimate roof renewal and not the attainment of permanency. Briefly, the treatment consists in removing from the fungus its water supply by preventing condensation so far as is practicable. And condensation is decreased by insulating the outer roof surface, the extent of inhibition depending upon the amount of insulation.

There are certain inherent limitations to this treatment which prevent the full attainment either of water-supply removal or of sterilization. First, it is impracticable on account of excessive initial expense to lay enough insulation to wholly prevent condensation within the roof plank even in moderately cold winter weather. Second, certain fungi are suspected of having a faculty—once they are well developed—of manufacturing water to a limited extent through a decomposition of the wood structure itself, provided said decay is deep seated and protected from too rapid evaporation. That is, water in its liquid state is not absolutely necessary for their maintenance. The important characteristic of this treatment is therefore a retarding action accomplished by making the environment as unfavorable as practicable.

Top insulation has the effect of moving the plane or locus of condensation for any given set of atmospheric conditions nearer the outer surface of the plank than before, and in mild weather of eliminating it entirely. In other words, the rate of condensation is reduced, as is also its duration, resulting in checking inroads of disease already established, and also in lessening the susceptibility of timber to further infection.

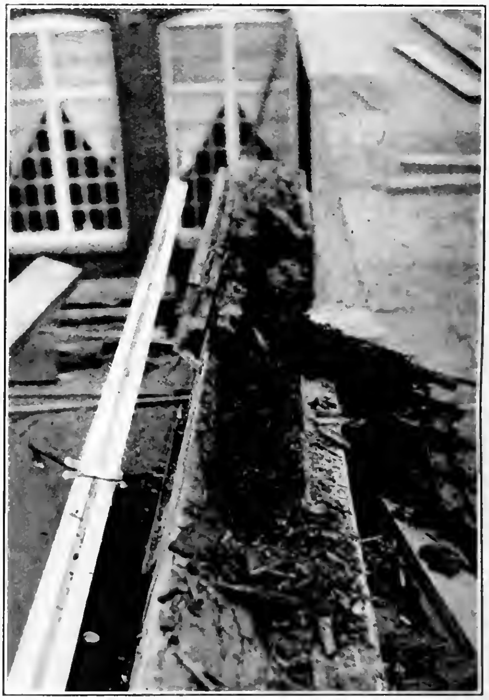

Fig. 4 Typical Decay in Yellow-Pine Girders

Insulation should be in sufficient amount to entirely prevent condensation on the under side of the roof in most severe weather, and if wood, should itself be antiseptically treated. Creosoted yellow-pine boarding nailed to furring strips has been found to be an economical type of insulation. Cheap, open-grained lumber, preferably sap wood, should be used, since it readily absorbs the necessary amount of wood preservative. By laying it over furring strips, additional and especially effective and inexpensive insulation in the form of an air space is obtained. This type of insulation also adds materially to the strength of the roof plank; in fact, it may be made thick enough to support the old plank if the latter have become seriously weakened, and the importance of not interrupting production is paramount. The old plank, where dangerously decayed, would then be spiked to the new plank from below.

---

[1] "Locus of Condensation" may be defined as a plane whose temperature equals the dewpoint temperature of the contacting room air. Below this plane no condensation takes place; above it, condensation occurs with increasing activity as the top surface of the roof is approached.

In order to prevent entrance into the new insulating air space of warm, humid air from the room below (and therefore condensation which would otherwise occur within the upper insulating deck and would drip upon the lower untreated plank), it is necessary to have a waterproof membrane between the old roof and the new insulation. The old roofing paper may be left intact and used for this purpose, if practical. On one large weave shed the new insulation was laid directly on the tar-and-gravel roof without removal of gravel, except what could be easily brushed off. If considerable structural renewal becomes necessary, however, it will generally be found advisable to remove the roofing paper entirely, and after necessary replacements have been made, to lay down a two-ply roof over the same before applying the insulation.

An economic consideration of the question invariably shows that the additional insulation saves enough heat to help very materially in meeting fixed charges on the initial cost of installation. This is illustrated later. Furthermore, dripping from the ceiling, which may have been experienced previously, will be stopped.

Sometimes it is advisable to rearrange the heating system so as to obtain a more uniform distribution. In sawtooth buildings a portion of the heating surface should be placed under the plank and a portion under the glass, the object being to obtain a balance (that is, as little circulation of air as possible directly under the sawteeth) and thus maintain a uniform and somewhat higher temperature here, without, however, increasing the room temperature on the working plane. The effect is to decrease still further the rate of condensation within the old roof and the number of days of its occurrence during the year.

The most recent installation with which the author is familiar was completed a month ago under the direction of F. P. Sheldon & Son, Engineers and Architects, with which firm he is connected. The building is a sawtooth weave shed have a projected roof area of 116,000 sq. ft.

The weave shed is now twenty-three years old, and during the past ten years considerable portions of the roof have been replaced. For humidity, during approximately the first twenty years, it depended upon the admission of moist basement air through belt holes in the floor at each individual loom, the basement being traversed by a canal and containing more or less standing water. Recently, mechanical humidifiers were installed with the intention of maintaining a more constant relative humidity (approximately 75 per cent) than was before possible. The humidifier installation probably has accelerated roof decay somewhat, but, on the other hand, the basement may now be properly ventilated, and the present ravages of decay in floor plank, beams, and columns prevented, or at least materially retarded.

Fig. 5 General View of Contractors' Plant

Sixty per cent of the roof plank was so rotted as to need renewal. Two per cent of the 6-in. by 12-in. yellow-pine rafters, and 25 per cent of the 11-in. by 14-in. yellow-pine girders were replaced for the same reason. The good condition of the rafters is worth noting and is doubtless due in part to their narrowness, which tends to prevent any marked dip in the locus of condensation—see Fig. 3.

The technique in this particular instance was briefly as follows: The insulation consisted of $^7/_8$-in. square-edged, creosoted yellow-pine boarding nailed on $^7/_8$-in. creosoted furring pieces, resulting in a $^7/_8$-in. air space between the old roof and the new boards. The lumber was treated on the job by the hot-dip process, being unloaded direct from the cars to a storage pile within 40 ft. of the creosoting tank, which latter was of steel, 20 ft. long, 7 ft. wide and 5 ft. deep, and had ample capacity for 3000 ft. B. M. of lumber used daily. Boards were stuck with 6-ft. pieces every six boards and were divided into two sections for a given charge, each section fastened with a cable sling. An A-frame derrick (Fig. 6) made of two 50-ft. telegraph poles was used for lifting the sections into the tank. It also served in removing batches from the tank and hoisting them to the weave-shed roof. Heavy timbers were used to ballast the lumber being treated, and these were taken to and from the tank on a carriage moving on rollers, and were lifted from it by the derrick. A batch, after being lifted out of the hot creosote, was held over the tank and allowed to drain for three or four minutes. It was then hoisted to the roof, after which practically no more dripping occurred; the partial vacuum set up by the air and steam in wood cells, cooling, contracting, and, therefore, sucking in the excess surface oil.

Fig. 6 View of Derrick and Creosoting Tank

The creosote oil used on the job was furnished in a tank car placed on a siding some 300 ft. from and considerably above the creosoting tank, thus allowing a gravity flow in the pipe line connecting the two. Make-up oil was added each time a batch was removed, except that toward the end of the creosoting process, after all the oil had been placed in the tank, the amount of lumber per batch had to be gradually reduced. During treatment the oil was held at a temperature of about 230 deg. fahr. by means of high-pressure-steam coils having a total heating surface of 270 sq. ft., placed in the bottom of the tank.

The use of wet or unseasoned wood was apparently not detrimental, except for the fact that a longer treatment was necessary in order to insure thorough penetration by first boiling out the entrained water.

The creosote oil used was a modification of Grade 1, American Railway Association Specification, having a specific gravity at 59 deg. fahr. of at least 1.08, and giving, when distilled, no distillate below 392 deg. fahr., not more than 1 per cent below 410 deg. fahr., and not more than 10 per cent below 455 deg. fahr.

The penetration was quite thorough, the amount of oil used averaging 9.4 lb. per cu. ft. for a 20-hour treatment. The creosote cost \$0.29 per gal. delivered, which, reduced to a board-measure basis, added \$0.022 to the unit lumber cost of \$0.03, and made a total of \$0.06 per board foot for treated boards—labor and overhead for treatment included, but not laying. The labor of laying on roof amounted to about \$0.02 per ft. B. M.

Where plank were rotted at bearings, but fairly sound elsewhere, new bearing strips were spiked to each side of the rafter for necessary support.

Not more than one sawtooth for half its length was opened up at any one time, with consequent interruption to only that machinery under this particular section. This usually amounted to less than eighty looms for a period not over nine or ten hours.

Economic Considerations in Prolonging the Useful Life of Repaired Roofs

Consideration of the problem from the standpoint of economics shows, for this particular building, if the given insulation prolongs the useful roof life no more than *five* years, that it was warranted and preferable to an entirely new durable roof. Each additional year of life is therefore a net gain, as is also the very real and important (but in this case uncapitalized) saving due to substantially postponing the period in which greater interruption to manufacturing, incident with entirely new roof construction, would occur. The solution was based on the following approximate assumptions made after the necessary study of existing conditions:

1 Regardless of building decay, the felt-and-slag roof, on account of its age and condition, would have required replacement within one year at an estimated cost of $17,000.

2 If decayed members in need of immediate renewal were to be merely replaced by new, without the insulation feature, it was estimated that equal replacements would again be necessary within fifteen years.

Problem: Determine the minimum number of years by which the given insulation must prolong the useful life of the repaired roof in order to prove a financially sound investment, and preferable at this time to an entirely new durable roof.

a The cost of the project was approximately as follows:

Insulation, i.e., creosoted plank in place, including extra two-ply waterproof membrane	$18,000
Felt- and -slag roofing	17,000
Necessary renewals of plank, rafters, and girders, removal of old roofing, painting, etc.	28,000
Total	$63,000

b The minimum cost of an entirely new and durable treated wood roof on yellow-pine rafters and steel girders, including painting, complete erection, etc., was estimated at $110,000.

Working out several trial examples, it is found that the said insulation in order to be justified should add at least *five years* to the useful roof life. Sample computations follow.

(1) The approximate 20-year cost of the repaired roof *with insulation* (that is, the cost over its augmented useful life of 15 + 5 = 20 years) may be calculated as follows:

Initial cost (wholly depreciated)	$63,000	
Yearly interest at 6% = $3,780 having a value in 20 years if compounded annually at 6 per cent of	139,000	
		$202,000
150 tons of coal saved annually at $7 per ton = $1050, having a value in 20 years if compounded annually at 6 per cent of		39,000
Total 20-year cost		$163,000

It is worthy of note that the insulation saves annually in coal 1,050/18,000 or 6 per cent gross of its cost and vitally affects the computations by reducing the number of years by which the said insulation must lengthen the roof life in order to be justified.

(2) The approximate comparative 20-year cost of repaired roof *without insulation* is obtained as follows:

Cost of repairs good for 15 years and then wholly depreciated, $17,000 for roofing plus $28,000 for replacements [see (*a*) above]	$45,000
Yearly interest at 6 per cent = $2700, having a value in 20 years if compounded annually at 6 per cent of	99,000
Cost of equal repairs 15 years hence (probably reduced to $30,000), depreciation at 5/15	10,000
Yearly interest at 6 per cent = $1800, having a value in 5 years if compounded annually at 6 per cent of	10,000
No coal saved	......
Total 20-year cost	$164,000

(3) The approximate comparative 20-year cost of a new and durable roof having an assumed life of forty years is obtained as follows:

Initial cost, $110,000, depreciation at 20/40	$55,000	
Yearly interest at 6 per cent = $6600, having a value in 20 years if compounded annually at 6 per cent of	242,000	
		$297,000
100 tons of coal saved annually at $7 per ton = $700, having a value in 20 years if compounded annually at 6 per cent of		26,000
Total 20-year cost		$271,000

Conclusion

While it is realized that the foregoing assumptions concerning future prices are conjectural, there is apparently ample margin in the result to show the described treatment to be, in this case, an economical procedure. This factor is especially emphasized when the avoidance of serious interruption to production, which would have attended entirely new construction, is considered; as well as the fact that dripping from the ceiling, which occurred previously during severe winter weather, is prevented.

Several other decayed wood roofs have been similarly insulated within the past three or four years with apparently beneficial results, so that this treatment has passed beyond the purely theoretical or experimental stage.

It is easy for an engineer to recommend sweepingly entire roof renewal with more permanent material, such as concrete, treated plank, redwood, etc., as the only real satisfactory solution of a given problem, but the correct answer is ordinarily determined only after careful analysis and evaluating and balancing every factor pertaining to each individual case. Each situation has its own especial features which should be critically examined; and to an executive considering ultimate costs, the question of maintaining production is often of greater weight than building economics pure and simple.

The tremendous damage caused by "damp rot," which is progressing insidiously in many industrial plants today, should be brought to light and more fully realized. In some brick buildings with wood roofs disintegration has occurred amounting in three years to one-quarter the value of the structure; other buildings entirely of wood have been practically a total loss above the foundations in the same time. Even less rapid depreciation instanced in the nearer normal example given has more than a merely local effect. Besides handicapping the manufactory itself, and being reflected in the cost of goods to consumers, such losses must ultimately have an appreciable effect upon international trade, and are intolerable if this nation is to enter into forward-looking competition in world markets. Plainly, damp rot constitutes one affliction of which our modern industry must purge itself if the United States is to play its rightful part with increasing service as a great vital and industrial nation.

A wood preservative new in this country but used in Europe and particularly in Belgium for a number of years is aczol, which is composed of ammonia, copper, zinc and phenol. All of these component parts have been used to a greater or less extent in wood preserving work, but the novelty of this compound lies in the fact that the inventor has succeeded in producing it in soluble form. It is entirely soluble during impregnation and precipitates while the wood is being permitted to dry in the air. The drying causes the evaporation of the ammonia, which simply acts as a carrier of the other ingredients. The phenolic salts of copper and zinc become firmly imbedded in the wood fiber—in fact the sap and ligneous material is soluble in the solution and this liquid is replaced by the precipitated salts.

The impregnation of wood with creosote is accomplished by placing the wood in a large airtight vat. The air is then pumped out to as high a vacuum as possible and the heated creosote is put in under pressure. With aczol the process can be conducted without the use of vacuum and without heating the solution. Wood impregnated with aczol is much stronger than that done with creosote, due, probably, to the cementing action of the salt in and around the wood fiber. It is clean, dry, odorless, and fire-resisting, and can be tooled and worked exactly as untreated wood.

The material is manufactured in rather concentrated form and is diluted—six parts of the product to ninety-four parts of water—in the field.

Records of the use of wood impregnated with aczol have been kept in Belgium for the past decade. Coal-mine operators testify that "aczolated" timber has remained in its original sound condition for eight years. It has also been used successfully on wood paving and in railroad ties, where the rotting is extremely rapid, especially in some climates. It is predicted by a number of competent men that the use of aczol will rapidly displace that of creosote because of its greater durability and greater ease of handling.—*Chemical and Metallurgical Engineering*, Sept. 6, 1922, p. 509.

Spherical Gears

By CHARLES H. LOGUE,[1] SYRACUSE, N. Y.

The basis for a study of all gears whose pitch surfaces are in rolling contact is found in the study of the bevel gear. By acquiring this point of view, not only are the elementary features of bevel-gear design brought out and applied to spur gears, but also the real connection between the two types is shown. This is essential to a complete understanding of either. The author has specially endeavored to point out the necessity for a difference in the design of the teeth heretofore not considered, and to present the entire matter in the simplest possible manner.

The tooth action of all gears whose pitch surfaces roll upon each other is developed upon the surface of a sphere, within which these pitch surfaces are enclosed. A study upon this basis is essential to a complete understanding of the action of both spur and bevel gears.

To illustrate, let us begin with a pair of miter gears whose pitch radii are 1 in., and which will operate at a shaft angle of 90 deg.; the apex distance (spherical radius) being 1.4142 in. Now consider a series of spherical enlargements, maintaining the same pitch radii for the gears. It will be noticed, as this enlargement progresses, that the angle of the axes is gradually reduced and that the gears very soon assume the appearance of spur gears, the pitch cones gradually merging into cylinders, which are attained when the radius of the enclosing sphere, or the apex distance, reaches infinity. Practically, we may thus develop cylindrical pitch surfaces within the range of a good-sized drawing board. See Fig. 1.

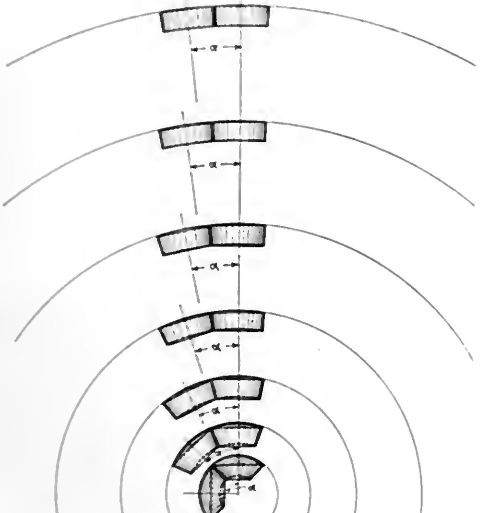

Fig. 1 The Evolution of the Spur Gear
(Angle $a=0$ when radius of sphere is infinite.)

Another way in which this fundamental may be illustrated is by considering the gradual enlargement of the radius of the crown gear, or our molding element. The pitch radius of the crown gear is the radius of the sphere, and its pitch surface is enclosed by one-half of the complete sphere. This pitch surface is a plane through the great circle, known as the "crown surface." Fig. 2 shows the nature of the engagement for a continuously enlarged crown gear with a pinion, the spherical radius being increased successively from *a* to *b* and from *b* to *c*. When the radius of the sphere is increased from *a* to *b* the angle of axes is reduced from A_1 to A_2, and then to A_3 by the increase to *c*. It is apparent, when an infinite spherical radius is considered, that the angle of axes *A* will be 90 deg. The angle of axes being 90 deg. and the ratio of reduction infinity, spur and bevel gears are identical.

Fig. 3 shows conical pitch surfaces within the sphere. The center of this sphere must be the common intersection of these conical surfaces, or the intersection of their axes. The angle of axes may be altered as desired, when new pitch cones will automatically form as shown in Fig. 4. By again considering a sphere whose radius is infinity, it will be apparent that an angular adjustment of the axis, as illustrated by Fig. 4, corresponds to a change in the distance between centers for spur gears. For spur gears the pitch diameters of both gear and pinion automatically form through a point which is the intersection of the line of action and the line of centers. Consider, for spur gears, that this occurs upon the surface of a sphere whose radius is infinity and apply this same development upon the surface of a sphere whose radius is the apex distance for bevel gears such as shown by Fig. 4. A drawing board for the development of tooth action should be a wooden sphere whose radius is the apex distance. For a pair of bevel gears of 49/11 ratio and 5 diametral pitch, operating at 90 deg., this "drawing board" would have a radius of 5.022 in. For the same gears operating at a zero shaft angle, the regulation drawing board is properly employed, on which we may also lay out a pair of gears whose angle of axes is 90 deg. when the ratio of reduction is infinity, or any pair of gears whose pitch surfaces are enclosed by a sphere whose radius is infinity. It will be noted that for any pair of gears enclosed by a measurable sphere, all tooth parts are properly expressed by angles, the only lineal dimension being the radius of the sphere.

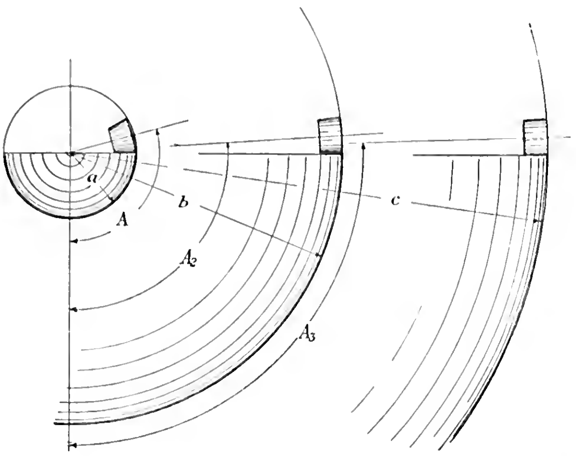

Fig. 2 Nature of Engagement for a Continuously Enlarged Crown Gear with a Pinion

Line Formation

All modern gear-cutting machines are based upon the molding process, by which, in theory, the teeth of the gear or pinion in process are molded or formed by the conjugating action of the teeth of a crown gear, or for spur gears, we may say, by the teeth of a rack. At present we will deal only with the development of the formation lines upon the pitch surfaces. This resolves itself into a study of these lines upon the pitch surface of the molding element, the transmitting of these lines to the pitch surfaces of the gear and pinion being entirely automatic. A defective line upon the pitch surface of the gear simply means defective crown-gear development.

For presentation at the Annual Meeting, December 4 to 7, 1922, of The American Society of Mechanical Engineers. All papers are subject to revision.

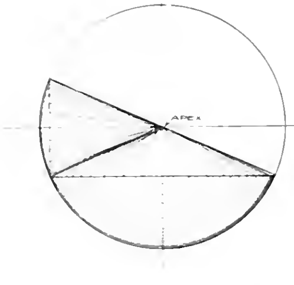

Fig. 3 True Pitch Cones

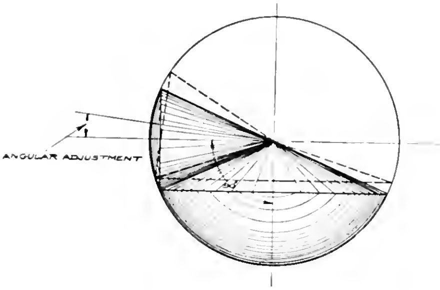

Fig. 4 Correct Separation of Pitch Cones

(Illustrating the increase in pitch cones due to an angular adjustment of axes. This corresponds to an increase in center distance for spur gears, and has a corresponding effect upon obliquity of action.)

Formation lines are developed upon the crown surface (pitch surface) of the crown gear. The outer circumference is spaced off to conform to the required pitch, and from each of these points upon the circumference we develop lines which approach the center or pole of the crown gear by means of an equiangular or logarithmic spiral of the desired angle. If a zero spiral, which will mold a straight-tooth gear, is required, we have only to draw radial lines from each point upon the circumference to the pole of the crown gear. Or if a spiral of, say, 30 deg. is required, the development line must be drawn so that any tangent forms a constant angle of 30 deg. with the radii vectores. That is, this line leaves a point upon the circumference of the crown gear at an angle of 30 deg. with a radial line drawn from that point, and continues obliquely toward the pole, forming a continuous line whose tangent with any radial line which may be drawn through it forms an angle of 30 deg., or any other desired angle of spiral. See Fig. 5. This same line being described from each point upon the circumference, the line formation of the crown gear is complete.

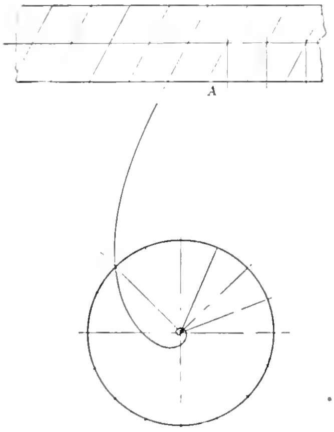

Fig. 5 Development of Formation Lines on Pitch Surface of the Crown Gear

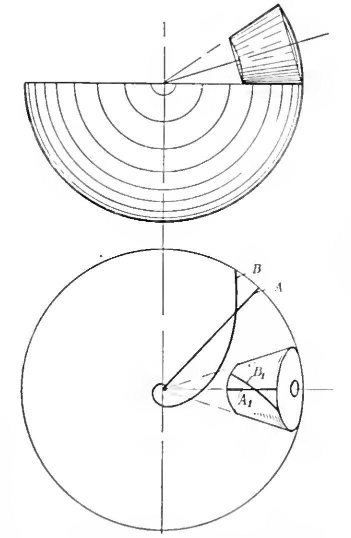

Fig. 6 Developed Lines on Crown Surface of Crown Gear

If we now consider the extension of the spherical radius to infinity we see that the pitch is laid off along a rack length, and this extension of the logarithmic spiral reaches the pitch surface of the rack as a straight oblique line at an angle from the vertical corresponding to the angle of spiral. See *A*, Fig. 5. In this extension, however, we refer to this angle as the "angle of helix." The spiral upon the conical pitch surface of the gear to be molded is the helix upon a cylindrical pitch surface. When the radius of the crown gear is infinite, radial lines become parallel lines, so that for straight teeth the developed lines upon the rack are simply drawn perpendicular to the lineal edge of the rack. Fig. 6 shows two developed lines on the crown surface. *A* is that of a zero spiral angle (straight tooth) and *B* a spiral development of about 35 deg. These lines are "printed" upon the pitch surface of the gear, as A_1 and B_1, by rolling the pitch surface of the gear over the pitch surface (crown surface) of the crown gear. The ratio of this rotation is as the sine of the pitch angle of the gear.

The Logarithmic Spiral

By reason of the growing interest in the logarithmic spiral and its application to spiral crown-surface development, also its interesting relation to the involute, it is thought that a treatment dealing with the spiral bevel gear should include a short description of the spiral. A graphical development is shown in Fig. 7. The radius vector is the distance from the pole to any point on the spiral. The radii vectores increase in geometric progression for a constant angle of advance. This angle (k) may be assumed and the ratio of progression P found as follows:

$$P = \frac{1}{2.7182818^{\frac{k \cot S}{57.293}}} \quad \ldots\ldots\ldots\ldots\ldots [1]$$

in case the spiral development is negative, toward the pole, or from the radius vector r_1; and

$$P = 2.7182818^{\frac{k \cot S}{57.239}} \quad \ldots\ldots\ldots\ldots [2]$$

in case the spiral development is positive, away from the pole, or, say, from radius vector r_{12}. S = angle of spiral.

We have $r_2 = r_1P$
$r_3 = r_2P$ or r_1P^2
$r_4 = r_3P$ or r_1P^3, etc.

When the spiral is developed toward its pole the value (negative) of the ratio P will be less than 1, and for a development away from its pole (positive) the ratio P will be greater than 1. The constant 2.7182818 is the Napierian base. The radius vector is the side opposite. The instantaneous radius of the spiral at any radius vector is the hypotenuse of a right triangle, as shown in Fig. 7 by heavy lines. This same triangular relation continues at all points on the spiral. Assuming a spiral

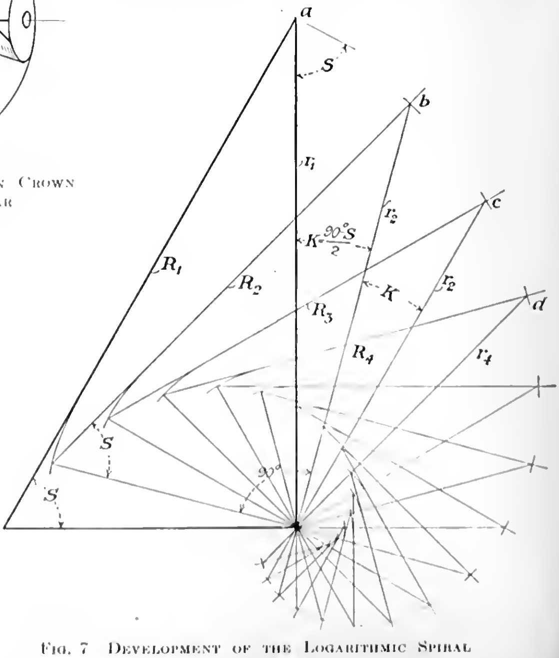

Fig. 7 Development of the Logarithmic Spiral

angle of 30 deg. and an angle k of 5 deg., the geometric ratio (P) for the spiral development by points, away from the pole, is found to be 1.163. Beginning with an initial radius vector, as r_{12}, of 1 in., the positive radii vectores increase in the following order:

r_{12} = 1.000 in. r_8 = 1.830 in. r_4 = 3.347 in.
r_{11} = 1.163 in. r_7 = 2.128 in. r_3 = 3.892 in.
r_{10} = 1.353 in. r_6 = 2.474 in. r_2 = 4.527 in.
r_9 = 1.574 in. r_5 = 2.878 in. r_1 = 5.265 in.

The geometric ratio for successive negative radii vectores toward the pole is 1/1.163 = 0.8598; thus r_2 = 0.8598 × r_1, or 0.8598 × 5.265 = 4.527; and r_3 = 0.8598 × r_2, or 0.8598 × 6.527 = 3.892, etc.

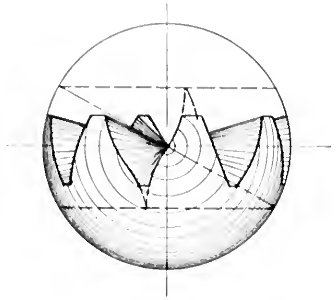

Fig. 14 The Involute Crown Gear (Grant)

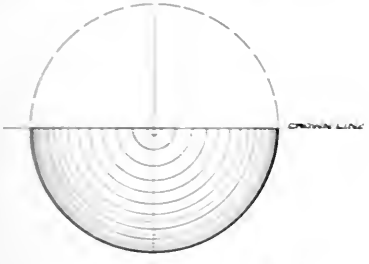

Fig. 9 Crown-Gear Pitch Surface

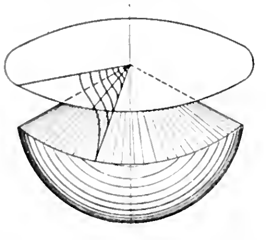

Fig. 12 Involute Described by Several Points on Disk of Fig. 11

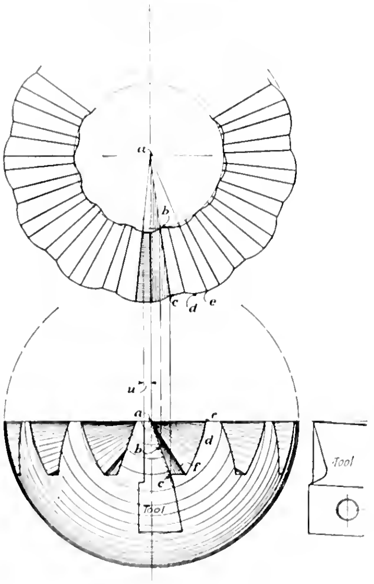

Fig. 15 Generator Tool Replacing One Side of the Molding Tooth

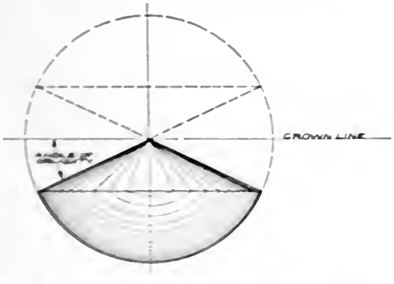

Fig. 10 Base Surface of the Involute Crown Gear

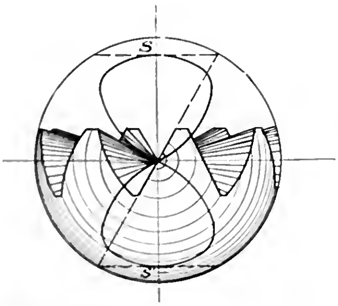

Fig. 13 The Octoid Crown Gear (Grant)

By making the angle $k = (90° - S)/2$, the spiral may be graphically developed by a series of points. Draw the first triangle to radius vector a as shown. Then draw potential radii vectores b, c, d, etc., at progressive angles k. Also draw base lines at right angles to these radii vectores. Now, with the pole as a center, strike an arc tangent to the hypotenuse R_1 of the first triangle, intersecting the base line of the radius vector b. From this intersection draw the second instantaneous radius (R_2) at an angle from the base line equaling the angle of spiral. This line will cut the potential radius vector r_2 at b, locating the second point on the spiral. Continue this development as far toward the pole as possible or as desired.

$$\text{Instantaneous radius of spiral } R \text{ (hyp. of triangle)} = \frac{r}{\sin S} \quad \ldots [3]$$

$$\text{Developed length of spiral} = \frac{r_1 - r_2}{\cos S}, \frac{r_1 - r_3}{\cos S}, \text{ etc.} \ldots\ldots [4]$$

that is, the developed length of the spiral is found by dividing the difference in the length of any two radii vectores by the cosine of the angle of spiral, which is the same as the length of a helical development across the face of a rack, the difference in the length of the radii vectores being the length of the rack face.

A logarithmic spiral may be described upon a crown surface by means of a fixture such as that shown in Fig. 8. A single helical thread raised upon a cylinder whose angle with the axis is the desired angle of spiral, will describe this spiral when rolled around with the center of the crown surface as a pole. Less than one complete turn of the helix is required. The spiral may be extended as desired by sliding the cylinder along its axis a and continuing the development. This helix may be developed on the cylinder by means of the action of an oblique line upon the pitch surface of a rack. This oblique line is the result of an extreme extension of the spiral. (See last paragraph under Line Formation.)

Infinity Radius

An infinity radius cannot be reached in practice, if it can be conceived at all. What is really meant by an infinity radius is a radius of such a length that no curvature can be detected within the length of the arc employed. This idea of an infinity radius will therefore vary with the means employed for describing the

length of the arc used and the skill of the draftsman. For a pair of 1 diametral pitch gears, the pinion radius being 6 in. and the ratio of reduction 25:1, we may ordinarily ignore the pitch radius of the gear in a graphical development of the tooth action and draw in the gear as a rack, as the pitch radius of the gear is 120 in. or 10 ft. Of course, a more careful or a more skilful draftsman might actually use a 10-ft. radius for developing the pitch circle of the gear within the action, but even the most careful or the most skilful man will finally reach a point where he will ignore the curvature and use a straight edge. Our measure of infinity is relative only, so that we may safely define rolling pitch surfaces within our conception as bounded by a sphere. This definition will be of material assistance in the study of the development of the teeth in the molding element, that is, in the crown gear, as it will show that the entire length of this crown tooth from its pole or apex to our conception of "infinity" has but one development.

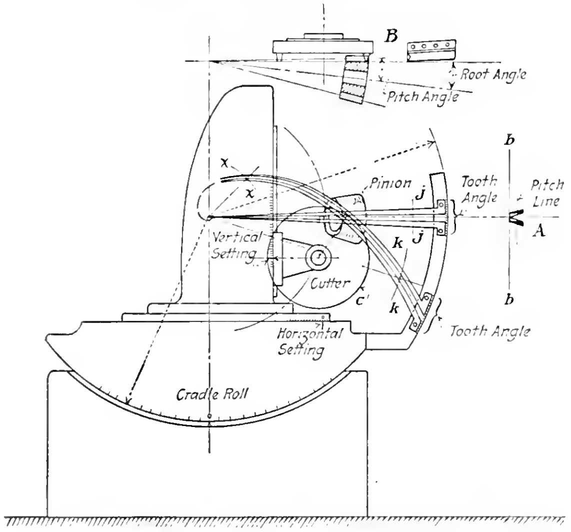

Fig. 16 The Gleason Cradle-Roll Generator as Applied to the Production of Straight-Tooth and Spiral Bevel Gears

The Crown Gear

Fig. 9 shows the pitch surface of the crown gear. The base surface is developed by a cutting line from the pole that is inclined from the crown line to the desired angle of obliquity as shown in Fig. 10. The involute profile is developed by means of a flat disk whose radius is that of the sphere. A series of points upon this disk will describe the involute the entire distance from the pole to the outer radius of the sphere (see Fig. 11). This development at the outer point of the disk, it should be noted, is upon the *surface* of the sphere, and it must be continued at all points. This disk is operated exactly as though rolled around between two base cones, the upper base surface or cone in Fig. 11 being indicated by dotted lines. Fig. 12 shows the involute described by several points upon the disk and illustrates the surface development of the crown-gear teeth.

Referring again to Fig. 11, let us assume that this drawing was produced by photographing a similar layout in which the spherical radius was, say, 10 ft. The total height of the involute, as measured on Fig. 11, is but a small portion of the same height on the original drawing. This height upon the original drawing would show, for all practical purposes, a perfectly flat profile; therefore, as far as this particular height of development is concerned, the radius of this sphere (10 ft.) is infinity. No matter what extreme spherical radius we may consider, an involute developed thereon will be that of Fig. 11 in case the scale of our conception is reduced accordingly. It is apparent that the accuracy of the involute tooth is limited only by our conception of infinity. Even then we are always brought back to Fig. 11 if the full involute development is considered. Fortunately this is never required.

The Octoid Crown-Gear Tooth

It is obviously impossible to generate a bevel gear with the involute form of tooth. (See Fig. 11.) The involute-generating tool would present a peculiar double-curved profile difficult to form, as will be apparent; also it would be necessary for this profile to change as the tool approached the apex; therefore the involute "molding" crown tooth cannot be duplicated in practice. The "octoid" tooth owes its existence to the fact that its crown-gear tooth is the only practical generating or molding tool: the profile being flat, no change takes place or is required as it approaches the apex during its cutting action. We have taken our conception of an infinite radius development of the involute and have arbitrarily applied this conception to measurable radii, as ordinarily employed in bevel-gear practice. This means that the larger the bevel gears engaging at a given angle or the smaller the angle of axes for given diameters, the nearer the action of the teeth approaches that of the involute. Also it is apparent that as we approach the small ends of the teeth, a further departure from the involute is made in any one pair of gears. Thus we may say that the nature of the action of the teeth in any pair of bevel gears is constantly changed at each point along the face length. Figs. 13 and 14, from Grant's Treatise, show the involute and the octoid crown gear. It will be noted that the flat "octoid" crown-gear tooth results in an "hour-glass" or "figure-eight" line of action, from which this form of tooth derives its name.

Generating the Teeth

In practice the teeth of the molding crown gear are replaced by cutting tools, which are of course necessary for non-plastic materials. Fig. 15 shows the planing tool which replaces one side of a tooth in the conventional crown gear. The length of face that may be cut is limited by the width of the point of this tool, or by *u*. Point *a* on this planing tool must be so located that its cutting plane represents both the side of a crown-gear tooth and the line of the bottom of the tooth space. To generate the opposite tooth space, a similar tool must be placed to represent the opposite side of the same crown-gear tooth. The point of this second tool must be located at *e*, its cutting edge representing the side *d* and the bottom or root line *f* of the crown-gear tooth. Both point *a* and point *e* must travel toward the apex *a′*.

Fig. 16 shows an outline of the Gleason cradle-roll generator as applied to the production of both straight-tooth and spiral bevel gears. The "molding teeth" for both types are here represented by tapered triangular wedges as shown at *A*, the angles of the sides of these wedges being formed to the angle of obliquity. The apex of these "wedges" is the apex or pole of the crown gear. Each pair of wedges are adjustable for tooth size by means of "tooth angle" settings, and their tops lie in a plane parallel with the cradle roll or on the crown line. In action the cradle rolls around the apex of the "crown gear" and the pinion or gear in operation rotates upon its axis, the action between the two being that of the pitch surface of a bevel pinion with the pitch surface of a crown gear as illustrated by Fig. 2. It will be noted that, as in Fig. 15, the tops instead of the pitch line of the crown-gear teeth are upon the crown surface and intersect the pole parallel with the cradle roll. This modification does not in practice seem to affect the accuracy of the gears, although the tops of the teeth in the molding gear (points of tools) should intersect the pole at an angle with the crown surface equal to the dedendum angle of the gear in process. The Bilgram generator does not contain this error, however. Any acting section of these molding teeth is taken with the pole as a center, as sections *j-j* and *k-k*. Proportional thickness is as the radial distance, as *x-x* to *k-k*, etc.

In practice the *straight* molding wedges are replaced by planing tools as shown at *B*, Fig. 16, and an approximation of the spiral wedge is secured by mounting a circular cutter, as *c*, so that its radius approximates the instantaneous radius of the spiral at the average apex distance of the gear in operation, as is shown. This cutter is rolled around the apex of the generator exactly as the spiral wedge and may be made, by various vertical adjustments, to represent a tooth in the molding crown gear; this, however, cannot be a true spiral but is an approximation thereto by means of a circular arc of a fixed radius. As shown in Fig. 16, vertical and horizontal settings are employed to locate properly the cutter

at its best average position, and these settings are also employed to allow the circular cutter to represent each side of a crown-gear tooth. Since the tops of the teeth in this cutter are set to the crown line, the axis of the gear in operation is set to its root instead of its pitch angle. The ratio of roll, however, is based upon pitch-surface contact. This pitch-surface contact does not actually occur unless we consider the pitch angle of the crown gears as being less than 90 deg. (see Fig. 17). The practical error, however, is slight.

Fig. 17 shows the engagement of two crown gears as embodied in the action of the machine in question. For spiral bevel gears a pair of such crown gears are necessary, as a right-hand spiral crown gear is required to mold a left-hand spiral pinion and a left-hand crown gear to mold a right-hand spiral gear. A study of the entire matter is therefore reduced to a study of these two crown gears. If they will not properly engage, we cannot expect a satisfactory product. The generator is the crown gear; that is, the action of the generating tools must be studied as if they were the teeth of the crown gear which, in theory, "molds" the teeth in the production gears.

Contact Lines

The important point to bear in mind when designing or when generating any "twisted tooth" gear, either spiral bevel or helical spur, is that their action and formation is exactly that of straight-tooth bevel or spur gears at any instantaneous section. The essential difference between twisted and straight-tooth gears is that in the former the instantaneous line of action across the face of the tooth is diagonal—at an angle with the pitch surface approximating the angle of the spiral or helix, while in the latter the action is along radial lines for bevel gears and along parallel lines for spur gears. Thus with straight-tooth gears the contact occurs instantaneously across the entire length of face, while for twisted-tooth gears it is distributed over different points of the line of action and across to adjoining teeth.

In case the axial distance between any two adjoining teeth (axial pitch) is less than the face width, we have, theoretically, a "pitch-point lock;" there being continuous contact at the "pitch point" or at the intersection of the line of action with line of centers, which is also the common point of tangency of the two pitch circles. This pitch-point lock should assure uniform velocities, but this is defeated mainly through errors in spacing. A pitch-point lock, as specified, is not essential to the quiet operation of any pair of gears: there is no sharp dividing line between successful and unsuccessful gears upon this basis. Any angle of spiral or of helix will help, and this assistance increases with the angle through a fairly uniform field. In turbo-reduction gears the axial pitch is often as low as one-twentieth of the face width, and the number of teeth in instantaneous contact across the pitch point is very often in excess of the number of teeth in the pinion. For such a condition we may say that an actual pitch-point lock is "approached," at least, but it is never attained in practice.

The total length of contact in twisted-tooth gears is exactly the same as for straight-tooth gears when based upon the number of teeth in contact upon the acting (virtual) section and the length of face: the number of contacts points times the length of bearing at each point is always equal to the number of teeth in contact upon the acting section times the length of the face.

Conventional Practice

In practice we often lose sight of the spherical nature of bevel gears. Fig. 18 shows the conventional development of the bevel gear by dotted lines. The back angles are machined flat and the back face or seat must of course be flat, but the spherical principle may be adhered to by adding any desired amounts, as b or b_1, to the "back cone distances" a and a_1, obtaining distances c and c_1 and employing these dimensions as a basis for all cutting and inspection operations. Both the generator and the testing machine must be set up in strict accordance with these dimensions. See Figs. 19 and 20.

It is apparent from a study of Fig. 18, also by reference to Figs. 3 and 4, that when bevel gears are designed to operate at any particular shaft angle (usually 90 deg.), operating clearance (backlash) must be cut in the teeth. In case the teeth are cut full size—that is, if the combined circular thickness of gear and pinion teeth is made equal to the circular pitch—the angle of axes must be increased in order to secure operating clearance, which is absolutely essential to the successful operation. It will be noted that operating clearance is an angular measurement; therefore, when gears are designed to operate at a shaft angle of 90 deg., the amount of backlash secured may be measured by operating these same gears without backlash and noting the angle of engagement, which must then be less than 90 degs. (see Figs. 21 and 22). Fig. 21 shows the gears held as they are to operate, with operating clearance between the teeth. Fig. 22 shows the effect of eliminating this clearance by dropping the pinion into snug engagement with the gear. In this figure the pinion has been dropped around the apex or shaft intersection, which is the center of the sphere. It will be noted that the back face of the pinion now leans away from the gear at an angle which is the same as the change in angle of axes. An oversize pinion would lean in, increasing the angle of axes. This angle might be termed "pinion inclination." A pair of pointers (Fig. 23) will show that for straight-tooth bevels the radial lines of the teeth intersect the crown line at some one point, and a measurement by pinion inclination will at once show whether or not this point of intersection is the apex or pole of the crown gear.

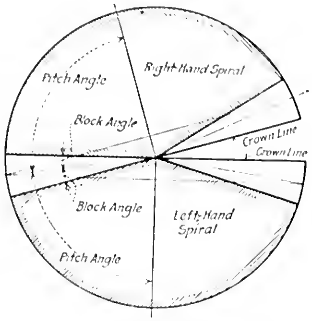

Fig. 17 Engagement of the Molding Crown Gears

When a pair of spur gears are moved into engagement, the tops of the teeth are first brought parallel with each other, and as the centers are farther reduced the engagement will occur at the extreme face of the tooth profiles and across their entire length. The backlash is gradually reduced as the gears are moved toward each other, with a continued deepening of their engagement until the desired amount of backlash is secured. This is their correct operating position and if the resulting distance between centers is not as required, the thickness and perhaps the depth of the teeth must be corrected accordingly. To parallel this procedure in the assembly of bevel gears, they must be rolled around each other with the intersection of their axes (center of sphere) as a center. Thus, to bring the faces parallel as the gears enter contact, the angle of axes must be increased an amount equaling the sum of their addenda angles, as shown in Fig. 24. Fig. 25 illustrates the result of an attempt at axial adjustment which is ordinarily thought to amount to the same thing as a parallel movement for spur gears. The axial position of bevel gears must be assumed as fixed: we are given no leeway in this respect except, of course, to determine the possibilities of assembly range when the gears are mounted in service.

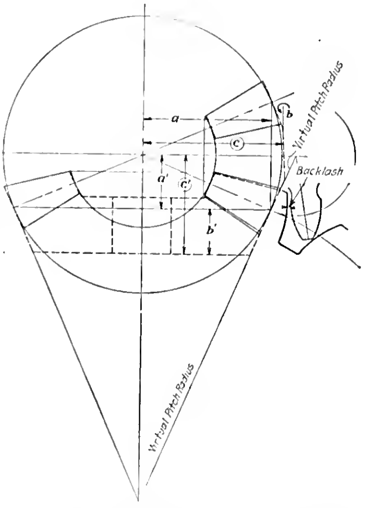

Fig. 18 Theoretical Construction of Bevel Gear, with Conventional Layout Shown in Dotted Lines

Effect of the Spherical Radius upon the Design and Assembly of Gears

Referring again to Fig. 1, it will be noted that as the radius of the sphere enclosing the pitch surfaces is increased, the change in the pitch across the length of the gear face is reduced; that is, the change in the pitch within the face length is more rapid with the smaller radii. When the radius of the sphere is infinite, there is no change in the pitch engagement; that is, the pitch is the same across the entire length of face. It follows that when a large sphere encloses the pitch surfaces, the change in the pitch relation is correspondingly slight. Thus, spur gears can be assembled as desired; any "error" in their axial location cannot affect their operating quality; also the pitch diameters and the obliquity of action adjust themselves to whatever center distance may be employed.

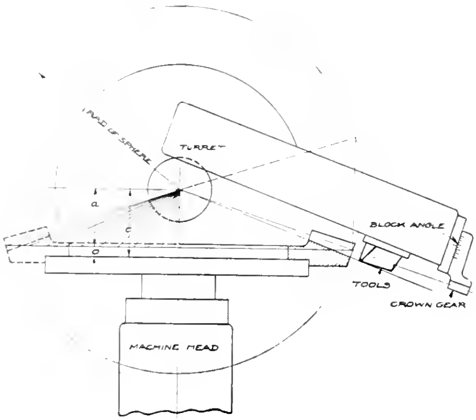

Fig. 19 Back Cone Distance on Gear-Tooth Generator

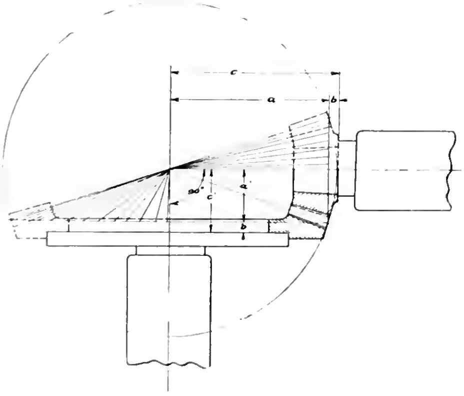

Fig. 20 Fixed Position of Testing-Machine Heads

Changes in the center distance of spur gears correspond to an angular change in the axes of bevel gears, so that an angular error in the shafts upon which bevel gears are mounted simply changes the amount of operating clearance, and aside from this cannot be called an error. Bevel gears are therefore essentially different from spur gears in that a correct axial location must be secured for the former, while it is of no importance in the assembly of the latter type. Spur gears need only be correctly cut and assembled on parallel shafts. Bevel gears must be so designed and cut that a *range* of axial adjustment (which does not affect spur gears) is allowable in their assembly. In fact, this allowable range of adjustment is taken as a measure of operating quality. It is impossible always to assemble bevel gears with their pitch cones intersecting exactly, or to maintain such an exact condition in service; therefore in the design of the teeth we must provide for the engagement of unequal pitches. A pair of bevel gears which will operate as desired in but one exact position, as specified, have little or no commercial value, while an equally accurate pair of spur gears would fulfill all requirements.

Tooth Design

Gear and pinion addenda, also proportional tooth thickness, as recommended by the Bilgram Machine Works represent excellent practice for 14½-deg. or 15-deg. straight-tooth bevel gears. We might well apply the same principle to 20-deg. gears or, for that matter, to those of any obliquity desired. For 20-deg. gears, however, the addenda may be made equal for both gear and pinion with good results, the addendum in each case being 1/pitch. The design of spiral bevel-gear teeth is too unsettled at this writing for any recommendation to be made and cannot well be included within the scope of this paper. Attention, however, should be called to the connection between spiral bevel and helical spur gears. In addition to this we also have the herringbone-gear practice to draw upon for points in the design of the spiral bevel gear.

A proper determination of the number of teeth in the gear and pinion is of first importance. The basis for this is the pitch diameters, obliquity, and angle of spiral. The working depth is properly a function of the pitch so that suitable profiles may be obtained, and this working depth is properly proportioned between the gear and pinion addenda on a basis of the ratio of reduction and the angle of obliquity. The difference between the gear and pinion addenda is the greatest for the lowest obliquity used (say, at 14½ deg.), and as the obliquity is raised the difference between the gear and pinion addenda is less pronounced. Thus the employment of equal addenda for 14½ deg. is prohibitive for the ratios, while for an obliquity of 22½ deg. it is good practice and may ordinarily be recommended for an obliquity of 20 deg. in case the pinion tooth is not too weak.

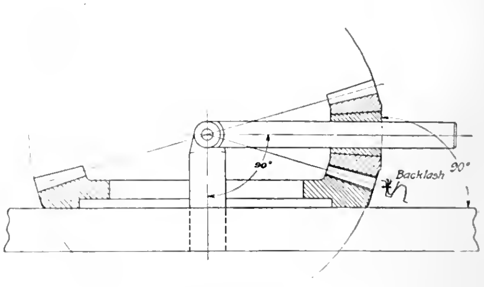

Fig. 21 Operating Position of Bevel Gears with Backlash between Teeth

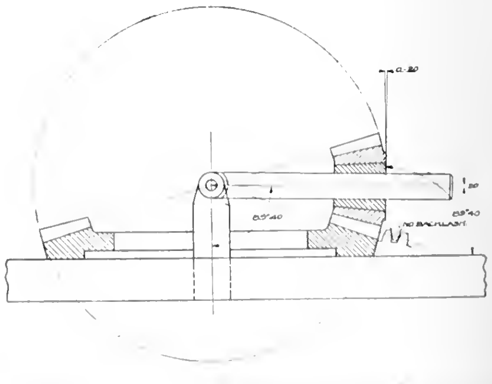

Fig. 22 Pinion Inclination to Eliminate Backlash Shown in Fig. 21

The usual bevel-gear reduction for automobile drives is around

5.1, varying from 3:1 to 6:1. In spur gears this would correspond to ratios between 9:1 and 36:1, the usual ratio being 25:1. For such ratios the angle of approach may be made equal to the angle of obliquity; that is, the slide at the beginning of the arc of approach may be 100 per cent without excessive wear. For obliquities of 22½ deg. or less, no sign of excessive wear has been found upon the approach with an angle of approach which equaled the obliquity; that is, with bevel-gear ratios in excess of 3½:1. On the other hand, it is recommended that the angle of recess be limited to 22½ deg. for all obliquities. Practically the same percentage of roll is found for each ratio, independent of the angle of obliquity, so that it is possible to reduce the number of teeth as the angle of obliquity is increased with no change in the relation of slide to rolling action. It might be suggested here that the allowable percentage of sliding contact on approach and on the recess be proportioned on a basis of the ratio of reduction, as it is apparent that no fixed rate can properly cover all ratios, or that the amount allowed on approaching action must be restricted to that which properly limits the amount of slide on the recess, at least for the usual automobile bevel-gear reduction.

It is thought that the mean percentage of sliding contact is a poor gage by which to measure wearing quality. The point to be watched is the maximum instantaneous percentage of slide. It has been noted that an angle of recess just a little to great has caused failure; also, when the maximum instantaneous points are within proper limits, that little or no improvement in wearing quality is found by a further reduction. With the maximum instantaneous points of contact within proper limits, it is thought that comparative wearing quality is properly gaged by the sine of the angle of obliquity, taking the torque from the base radius and as the sine of twice the angle of obliquity for given pitch diameters: the sine times the cosine being the sine of twice the angle, divided by 2. Thus, 14½-deg. gears may be compared with 20-deg. gears as the sine of 29 deg. to the sine of 40 deg.; that is, 0.6428/0.4848 = 1.33, or 33 per cent in favor of the 20-deg. gears, the pitch diameters being the same for each obliquity.

Mean Tooth Pressure

In designing the housings for bevel gears it is important that correct thrust loads be determined, especially when we are dealing with the spiral bevel gear. It is not the intention here to enter into these axial-thrust calculations, but simply to point out means by which the mean tooth pressure, as affecting the thrust loads, may be obtained. Ordinarily we are given a distance on the pitch surface of the bevel pinion one-third the face length from the large end of the tooth as the point from which this pressure may be calculated, but this is thought to be in error.

Suppose, for example, that the *average* pitch radius of the pinion is 1 in. and the pitch angle is such that the pitch radius at the small end of the pinion is 0.5 in. and at the large end is 1.5 in. The motor torque is, say, 4000 in-lb., therefore the pressure as figured at the small end of the tooth of the bevel pinion would be 8000 lb.; but the pressure at the large end of the tooth would be 2667 lb., not 2000 lb., as might be our first estimate. This pressure (2000 lb.) is attained at a pitch radius of 2 in. From this it is evident that the point of mean pressure must be located somewhat toward the small end rather than toward the large end of the tooth.

Pressure on the teeth varies, of course, inversely as the pitch radii, but the pitch radii do not change with the proportionate distance from the average along the pitch surface. Plotted values for pitch radii and proportional tooth pressure will develop a hyperbolic curve, not a straight line. We have:

$$M = \frac{c}{d - e} \log_e \frac{d}{e} \quad \ldots\ldots\ldots\ldots\ldots\ldots \quad [5]$$

in which M = mean tooth pressure
c = motor torque in inch-pounds
d = maximum pitch radius
e = minimum pitch radius
r = mean pitch radius.

To locate the mean pitch radius, we have:

$$r = \frac{c}{M} \quad \ldots\ldots \quad [6]$$

As an example, let c = 1000 lb., d = 1.5, and e = 0.5. Then d/e = 1.5/0.5 = 3.0, for which $\log_e$ = 1.0986. Whence—

$$M = \frac{1000}{1.5 - 0.5} \times 1.0986 = 1000 \times 1.0986 = 1098.6 \text{ lb.}$$

and—

$$r = \frac{c}{M} = \frac{1000}{1098.6} = 0.9102 \text{ in.}$$

The average radius is 1 in. Ordinarily it would appear sufficiently accurate to consider the *average* as the mean pitch radius and figure thrust loads accordingly.

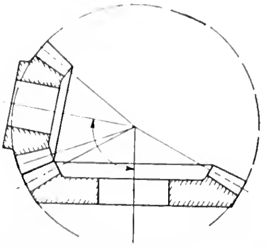

Fig. 24 Bringing the Faces Parallel as the Gears Enter Contact

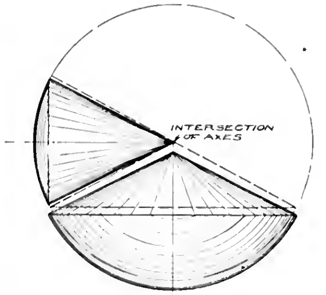

Fig. 25 Effect of Axial Adjustment of the Pitch Cones of a Pair of Bevel Gears

(Dotted lines illustrate automatic rearrangement of pitch cones in case gear is moved away from pinion along its axis in an attempt to increase the backlash; that is, to obtain operating clearance not allowed in cutting the teeth. The real apex point is the intersection of the gear and pinion axes. The figure shows the lines of action crossed due to the movement of the gear outside the sphere.)

A Discrepancy in Calculated Tooth Thickness

Allowing for the chordal thickness of a bevel-gear tooth upon the virtual pitch radius along which the back face of the teeth are machined, also allowing for the chord of the sphere enclosing the pitch surfaces proper, there is still a discrepancy between the calculated and the required thickness of the teeth. A pair of bevel gears will not assemble as in their fixed operating position (see Figs. 19 and 20) until the teeth are cut somewhat smaller than the figures given. Undoubtedly the calculations are in error: the profile of the teeth upon the sphere is evidently not properly understood, as the discrepancy varies with the radius of the sphere. For a radius of 3 in. (5 pitch) it is necessary to reduce the size of either gear or pinion approximately 0.015 in., while for a spherical radius of 5.5 in. the usual amount necessary is 0.010 in. This is offered as an interesting point which has up to the present time defied solution, although the explanation is probably simple enough, as are all fundamentals of gear design.

Suggestions as to Standardization of Machine Tools

By FRED H. COLVIN[1] and K. H. CONDIT,[2] NEW YORK, N. Y.

THERE are two outstanding phases of the problem of standardization of machine tools, one as it affects the builder and the other its effect on the user of the machines. The former can be left to the builders themselves, as it affects the cost of manufacture and the amount of capital invested. The latter, the effect of standardization on the user, is of direct interest to all.

One of the first considerations in making or advocating any change from existing practice is whether the benefits to be derived are worth the cost. This holds good with the proposals for standardization of machine tools, and this question of cost very frequently makes what we are pleased to call standardization really a matter of elimination. We usually eliminate unnecessary sizes and make those which we retain the standard, rather than adopt an entirely new standard which is the result of careful investigation, calculation, and experiment. And while this may not be the ideal procedure, it is the practical solution in most cases. Devising a new standard too often means simply adding another variety rather than eliminating many which are now in use.

The Advantage of Uniformity

Those who deprecate this unscientific method of standardization should remember that one of the greatest advantages of standardization, perhaps the greatest, lies in uniformity rather than in perfection as to the standard adopted. Taking the gear shift of an automobile as an example, the question of superiority in any particular shift sinks into insignificance in comparison with the advantages of having any one of the gear shifts adopted as standard on all cars. The typewriter keyboard is another excellent example of this.

Standardization of machine tools from the standpoint of the user can be confined to two specific points, work-holding and tool-holding devices. The former affect principally the spindle noses of lathes and the T-slots of planers, milling machines, boring machines, drilling machines, and the like. Tool-holding devices affect the spindle noses of milling machines and drilling machines, turret holes, tool posts, grinding-wheel spindles, etc. And while these look innocent enough on the surface, it does not take long to find that it involves the old controversy as to tapers, which is enough to start a heated argument in any shop.

Interchangeability and Accuracy

Every mechanic who has handled precision work knows that it is not practicable to interchange lathe chucks on very accurate work with the idea that the chuck will run dead true on more than one machine. On the great majority of work, however, the ability to change chucks from one lathe to another, without the bother of making adapters (which usually add considerably to the overhang) would be of great service in many shops. In the same way fixtures should be interchangeable from one machine to another by the use of standard T-slots in the tables and probably a standard distance of the first slot from the edge of the table.

The inability to use given turret tools in more than one machine imposes an unnecessary expense on the shop overhead and also directly affects future sales of the machines in question. The builder whose machine has odd sizes of turret holes, for example, will have a hard time securing an order from a shop equipped with machines having a different size, even though one be as logical as the other. And while an order once secured might tend to force a continued use of this machine, it is apt to prevent an order at least as often as to secure one.

T-Slots

The standardization of T-slots is probably the easiest place to make a beginning, and here again it will undoubtedly result in the elimination of perhaps half the sizes, retaining only those which are necessary. A canvass of the total number of each size of T-slot cutters sold should make it easy to select the sizes most in use.

But even T-slots have several points to be considered: the width of slot opening, the width and depth of the T for the bolt head, and the depth of metal over the slot to resist pulling out a piece of the table. Uniformity as to this latter feature is, however, less important than the width, as that is what affects the use of tongs for locating milling fixtures and the like. The distance of the outside T-slots from the edge of table is also important.

It may be well to emphasize right here that no matter what is being standardized, it must be remembered that a definite tolerance must be given in each case. And in considering tolerances, let us bear in mind that the modern tendency is toward a unilateral tolerance—a plus tolerance on the slot or hole and a minus tolerance on the part which fits into it. Let us get away from the "plus *or* minus" tolerance on the same piece.

Standardizing T-slots also involves the standardizing of the T-bolts which are to be used in them. Carl Barth has given this careful attention and his recommendations have been taken up by H. Cadwallader, Jr., of Philadelphia, who now manufactures T-bolts to the Barth standards.

Another point to be considered in standardizing work and tool-holding devices is to have the same size on as many machines as may be practicable. It may often be convenient to use the same chuck on a 14-in. and a 24-in. lathe. This is probably too big a range to be adequately covered by the same spindle nose, but it is quite possible that the same size of nose might be used on two or three sizes of machines. Some builders already use the same feed box on different sizes of machines, which is a very sane and sensible practice.

There is considerable talk of standardizing machine capacities, such as the swing of a lathe. But while it would be more convenient all around to know just what was meant by a 14-in. lathe, this is really a problem of the salesman and the buyer. If the seller prefers to cut prices by selling a 17-in. lathe under the name of a 14-in. lathe, it hardly affects the user so long as the work-holding or tool-holding devices on the lathe are standardized.

The milling-machine builders have perhaps done more in this line than builders of any other machine tools. A No. 1 machine now has approximately the same capacity in nearly all makes. The use of numbers, however, has little to commend it, whether it be milling machines or wire gages, and it is believed that main dimensions as to capacity would be more satisfactory to users.

Standardization Does Not Hamper Progress

One of the stock objections to standardization is that it prevents progress and the development of new ideas and designs. If, however, we consider that the Society of Automotive Engineers has done more in the way of standardization than any one else and then note the development in the automobile industry, this objection is easily answered. Is it likely that automobiles or other machinery would be more highly developed if each builder used a special-sized nut with a special thread? Standardization of such parts as nuts, piston pins, and other parts simply means that the designer calculates his requirements, such as to the kind of loads and stresses, and selects the standard part which meets his needs instead of designing an entirely new nut or pin of a slightly different size. It must also be remembered that standards are not as fixed as the pyramids, but can be changed whenever occasion really demands.

While all our efforts at standardization at this time should be devoted to such details of machine tools as affect the user, such as work- and tool-holding devices as has been pointed out, it is quite probable that the machine-tool builders themselves may find further standardization desirable. Research may show that bearings of certain dimensions are best for given spindle loads and speeds. Designers would then determine the load to which the spindle of a new machine would be subjected, and after considering all the conditions, would select the proper bearing from a list of standards.

[2] Editor *American Machinist*. Assoc-Mem. Am.Soc.M.E.

Presented at the Springfield Regional Meeting of The American Society of Mechanical Engineers, Springfield, Mass., September 25–27, 1922.

This would simplify manufacture and greatly reduce the number of tools and gages to be carried in stock, as well as the stock of bearings themselves. This phase of the matter, however, does not concern the user of the machine, and he will do well to confine his efforts at securing standardization to such features as concern him directly.

The Problem of Securing the Adoption of Standards

In addition to the engineering and economic aspects of machine-tool standardization, there is the adoption phase—for all practical purposes this is a selling problem. The best engineers of the United States, or of the world for that matter, may gather in solemn conference and decide that certain standards shall be established, but they have no power to do anything more. If the manufacturer concludes that his present practice is sufficiently satisfactory and is not convinced of the need for innovation, there is little that the standardizers can do.

Very often the problem is essentially a "selling" problem and one for which the average engineer is temperamentally unsuited. Diplomacy, tact, persuasiveness—the stock in trade of the salesman—are needed at this stage of the game. Even they would be futile if no means were at hand for gathering together the men who must make sacrifices if a standard is to be adopted, for lacking such means the task of reaching each man individually and reconciling his views with those of all the others, would be herculean.

The machinery for handling the engineering and industrial problems connected with this phase of standardization already exists in the American Engineering Standards Committee, and the rules of procedure of this committee are designed to bring about the early adoption of approved American Standards. To this end all Sectional Committees are required to include in their personnel representatives of *all* organizations which are in any way interested in the manufacture or use of the standard under consideration. Since these organizations are officially represented on the committee which prepares the standard, it is obvious that the members of these organizations are committed to the adoption of the standard to the extent that any individual or firm is committed by the actions of an organization to which he or it belongs. Just how well this arrangement is going to work out when it comes to universal adoption of a standard it is too soon to say, but at least the plan shows promise.

It may be that the Division of Simplified Practice of the Department of Commerce recently organized by Secretary Hoover will have a part to play in securing the general adoption of the standards for small tools and machine-tool elements which are to be developed by the Sectional Committee sponsored jointly by the National Machine Tool Builders' Association and The American Society of Mechanical Engineers. This, of course, will be determined as the work of the Committee progresses.

So far the Division has done its best work in fields of industry not closely connected with engineering. It is coöperating, however, to the fullest extent with the American Engineering Standards Committee in furthering the establishment and introduction of standards.

Standardization is a tremendous job and it may prove to be one beyond the capacity of any standards body yet organized. But it is a job that must be done and some means will have to be found. For the present, existing agencies should be given the fullest possible support by every one interested, manufacturer or user. Whatever is accomplished will benefit every one and is well worth any sacrifices that may have to be made.

Standardization of Small Tools

How the First Cost of Small Tools Can Be Greatly Lowered, without Sacrificing Their Efficiency, by the Adoption of Standards That Will Permit Their Manufacture on a Quantity Basis

By CARL J. OXFORD,[1] DETROIT, MICH.

Machine tools and small tools are so closely related to each other and interdependent that their respective developments logically should go hand in hand. In the past we have had instances of close coöperation between machine-tool builders and small-tool manufacturers. The results have invariably been noteworthy, and beneficial both to the coöperating firms, and to the tool-using industries in general.

Powerful and rapidly operating machine tools may be designed and built, but their success is largely nullified if they require cutting tools of prohibitive cost and of short life. Conversely, small tools may be developed which with the proper machine tools will produce wonderful results, but which again with unsuitable machines are complete failures.

We have been, and are still, passing through a period in our industrial development where reduction of expenses has become the watchword. Particularly is this true of those expenses which may be classified as production costs. Facing, as we now do, keenly competitive markets, it becomes necessary to cut the cost of production to the core, if the manufacturer is to show a balance on the right side of the ledger.

There seems to be but a scant likelihood that either raw-material or labor costs will recede to a lower level in the near future. In fact, we have recently seen slight increases in both. The lowering of production costs must therefore be accomplished through improvement in methods, and through increased productivity and efficiency of tools and equipment as compared with first costs.

It is the primary purpose of this paper to point out how greatly the first cost of small tools can be lowered, without sacrificing their efficiency, by the adoption of standards that will permit manufacturers of tools to produce on a quantity basis.

Classification of Small Tools

Twist drills, reamers, and milling cutters all are classed as small tools. In this paper only these three types will be considered. Usually the manufacturer classifies them as being either standard or special.

Standard tools are those sizes and designs which are regularly catalogued and carried in stock by the larger manufacturers, while special tools are those made up to the customers' specifications.

There exists at present a fair uniformity of general dimensions in the tools catalogued as standard by the various makers. This is a step in the right direction; but the belief is expressed here that this uniformity could be carried more into detail, and that the number of standard items listed could be cut almost in two without any serious handicap to the metal-working industries in general.

It is difficult to realize, by those not actively engaged in the small-tool business, what a wide variety of styles and sizes are catalogued as standard tools. An examination of several tool-manufacturers' catalogs shows the following average number of items:

Twist drills	3400 items
Reamers	2200 items
Milling cutters	4500 items

Roughly this makes a total of 10,000 items. Certainly this ought to be enough of a variety to take care of every conceivable requirement. That such is not the case, however, is illustrated by the fact that small-tool manufacturers are annually making thousands of items of tools not listed in their catalogs, and must continue to do so as long as their customers insist on having them.

Standard vs. Special Tools

It is conceded that there are numerous instances where special

---

[1] Chief Engineer, National Twist Drill & Tool Co. Assoc-Mem. Am.Soc.M.E.

Presented at the Springfield Regional Meeting of The American Society of Mechanical Engineers, Springfield, Mass., September 25–27, 1922.

tools are necessary; but the statement is made advisedly that in many shops from 40 to 60 per cent of the work now performed with special tools could be equally well performed with standard tools, *and at a much lower tool cost.* To accomplish this it would be necessary, however, to educate the designers of both the manufactured article itself, and of the various holding and locating fixtures, to the importance of adapting their designs to the most economical uses of tools.

Instances are numerous where no end of troubles are encountered in machining because the designers have paid more attention to the purely technical side of design than to the practicability of performing the various machine operations specified.

In the production of many manufactured articles the cost of perishable cutting tools, such as drills, reamers, and milling cutters, represents a large percentage of the total productive cost. As a consequence the question of efficient and long-lived tools has come in for considerable attention. The present tendency, however, seems to be toward the use of special tools where an increased production is desired, or where trouble is encountered.

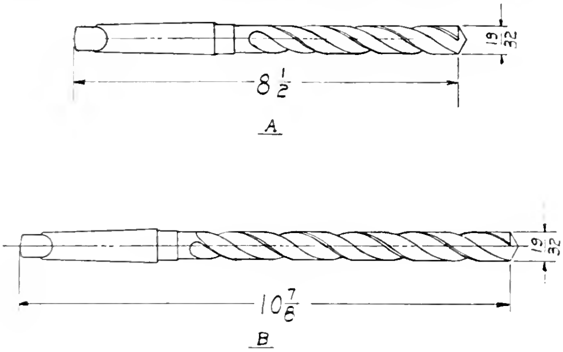

Fig. 1 Comparison of Standard-Length and Extra Long Taper-Shank Twist Drills

This is believed to be a fallacy in great many cases. For if a little time and effort is expended in adapting the conditions, such as surface speeds, chip thickness, and holding devices, it is often found that equally good or better results can be produced with standard tools than with special tools, although the latter must be obtained at a much higher price.

In addition to the higher price of special tools, it must be borne in mind that these are only made up in quantities as specified by the user. Hence the source of supply is restricted, and deliveries are subject to delays. Standard tools, on the other hand, can be purchased on the open market and can usually be delivered from the manufacturers' stock.

Relative Costs

Standard tools which are carried in stock by both manufacturers and dealers can naturally be made up in fairly large quantities. Usually from about five hundred to ten or twenty thousand of each size and kind can be put through the factory at one time. This means that many of the benefits accruing from quantity production are realized.

There is little time lost in setting up the machines, operators become more efficient on repetition operations, and in many instances it is possible to utilize multiple equipment and other time-saving devices.

The non-productive overhead incidental to every order is also spread over a great number of pieces, so that the amount chargeable against each piece is very small. All these conditions combined result in a low unit cost.

Compare this with the cost of producing special tools. These are as a rule ordered in small quantities ranging from one to ten or twenty pieces. Highly skilled all-around machine operators must be employed for this class of work. There is just as much time lost in setting up each of the various machines for one piece as for one thousand or ten thousand. There is no opportunity of using multiple equipment on such small numbers of pieces, nor do the machine operators acquire any increased efficiency from repetitions.

Non-productive overhead expenses are nearly as high for one or two pieces as for several thousand. The difference is that in one case these expenses must be absorbed by one or two pieces, while in the other case they can be distributed over a very great number. It is obvious how this will affect the respective unit costs, and eventually the price at which the tools must be sold.

Concrete examples of comparative costs will perhaps illustrate the point more forcibly. Let us compare the two twist drills *A* and *B*, Fig. 1. Both are $^{19}/_{32}$ in. in diameter and of identically the same design throughout except that drill *A* is of standard length or $8^1/_2$ in., while drill *B* is $2^3/_8$ in. longer, or $10^7/_8$ in. Five hundred of the drills *A* were made at one time, this being a standard size. The drills *B*, being special, could be made only in quantity as specified by the customer, in this case six.

The direct labor cost of *A* proved to be only 38 per cent of the corresponding cost of *B*. Adding the non-productive overhead, chargeable against the respective orders of which these drills were a part, the total cost of the standard drill *A* was found to be but 21 per cent of that of the special drill *B*.

Representing this in another way, we may say that the increase in length of *B* over *A* was 28 per cent, while the increase in cost was 480 per cent.

Similarly, we may compare the two milling cutters *C* and *D*, Fig. 2. The special cutter *C* is slightly smaller than the standard cutter *D*, yet, owing to the quantities manufactured in each case, the total cost of the cutter *C* was found to be 270 per cent higher than the corresponding cost of *D*.

These are but ordinary illustrations of conditions as encountered by every tool manufacturer.

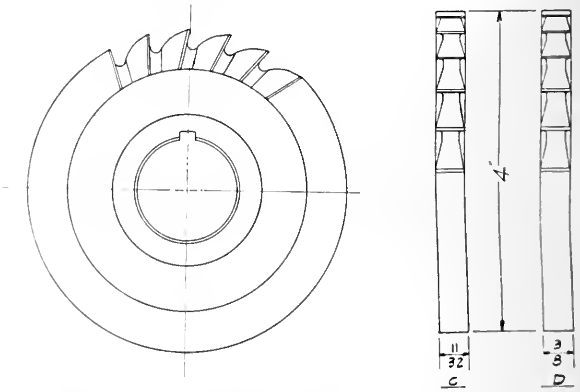

Fig. 2 Standard and Special-Size Milling Cutters

Necessarily the cost of producing must be reflected in the cost to the consumer. Pursuing this line of thought, it becomes evident that the high cost of special tools is eventually levied against the manufactured articles on which the tools are used, and in turn is passed on to the purchaser of these articles.

Let us suppose that a certain operation requires a special milling cutter costing \$30 and that the life of this cutter is 4800 pieces. If we are able to adapt this same operation to the use of a standard milling cutter of approximately the same dimension we shall have effected a considerable saving. This latter cutter can probably be bought for about \$18.

The tool cost for one operation is then reduced from \$6.25 to \$3.75 per thousand pieces. With a great number of machine operations on which such savings may be effected, it is easily conceivable that the results may mean the difference between a possible business loss and a tidy profit at the end of the year.

Elimination of Special Tools

It has already been stated that the total elimination of special tools is impracticable, for there will always be conditions now and then where a standard tool cannot be used; but there can be no doubt that the number of special tools used in the average manufacturing plant, with a little foresight, can be greatly reduced. Engi-

neers and designers responsible for the design of both the manufactured product and of the various jigs and fixtures, must be brought to realize the great economic advantage of standard tools over special tools. Especially is this true where production of large quantities of duplicate parts are involved.

A jig or fixture is a comparatively permanent thing, while cutting tools are in many cases very short-lived. Therefore a small additional expenditure, in order to adapt such jig or fixture to the use of standard tools, eventually becomes a highly profitable investment.

Numerous cases can be mentioned where such simple expedients as the shortening of a jig bushing or the slight reduction in height of some projection on a milling fixture will mean from 20 to 50 per cent reduction in tool costs for that particular operation, inasmuch as it will permit the use of standard tools.

From the author's own experience in the manufacturing of automotive parts there come to mind, too, several instances where the factory, in order to get out the required production, was compelled to ask the engineering department to alter its designs sufficiently so that practical and economical cutting tools could be used. It is a regrettable fact that many engineers, either through ignorance of, or through failure to attach sufficient importance to, small-tools requirements, are in this way wasting money that legitimately should be used either to reduce the cost of the goods or to pay a profit on the invested capital, as the case may be.

Technical schools and colleges would render a real service to the metal-working industries if they were to include in their machine shop curriculum at least a limited amount of instruction along these lines.

It may be properly argued that some of the tools now embodied in the tool manufacturer's standard list do not represent the highest degree of efficiency, and that there are certain other tools, now regarded as special, which will give better results. This is a sound and logical development of the small-tool industry, a development which should be encouraged through the elimination from the standard tool list of obsolete styles and designs, and the substitution of tools, developed through experience and research, that have proved more efficient under all conditions.

We have, for instance, the matter of numbers of teeth in milling cutters and numbers of flutes in reamers. The majority of manufacturers maintain a fair uniformity in this respect, based more or less on practical experience. However, materials and machine-tool equipment are being developed which in many cases demand numbers of teeth or flutes varying from the old established standard. As a consequence many users of tools are specifying numbers of teeth according to their own pet ideas. Obviously this at once classifies the tools as special, because it is impossible for the manufacturer to anticipate consumers' whims.

It seems reasonable to assume, though, that there is one number of teeth or flutes which in general will work most satisfactory. It is in cases such as these that standardization becomes important from an economic point of view.

If standards can be established, and these adhered to, the consumers will derive great benefits through the elimination of expensive special tools and the substitution of more moderately priced standard tools.

For the general good of the metal-working industries as a whole, a program of standardization should be carried out. Attempts should be discouraged to capitalize by attributing fancied advantages to minor construction details and charging special-tools prices for those which legitimately are standard. Standardization will undoubtedly go far toward the total elimination of such practices.

Reduction in the Number of Standard Tools

It is also believed that a material reduction in the number of tools now regarded as standard can be effected without hardship to any one.

A majority of the tools used in the metal-working industries today are made from high-speed steel. They are consequently expensive, due to the high cost of the raw material. When it is remembered that a small-tool manufacturer must carry in stock some 5,000 to 10,000 items of these tools, each in sufficient quantities to care for the possible requirements of the trade, it is easily seen that this imposes on him a large overhead, merely as interest on the investment involved. Therefore, the elimination of a number of items will mean a corresponding decrease in the price of those remaining. Some suggestions are given here, which if followed will accomplish much in this direction. It is at least hoped that these suggestions may serve as a basis for future action. The actual carrying out of the changes proposed must of course be left to the tool manufacturers, but they can do so only after the consumers have been educated to the great economy made possible.

Let us first consider the ordinary straight-shank twist drill with which every one is familiar. In the sizes up to and including 1/2 in. diameter we find from Tables 1 to 4, inclusive, 166 standard sizes listed, as follows:

Straight-shank wire drills	80
Straight-shank letter-size drills	26
Straight-shank drills—jobbers' lengths	31
Straight-shank drills—taper-shank lengths	29
Total	166

Power, Paper, Tools and Textiles Featured at Springfield Regional Meeting

New England Engineers Extend Hearty Welcome—Strong Papers Presented—Dean Kimball Broadcasts Important Message—New A.S.M.E. Section Formed

THE ENGINEERS of New England gathered at the Hotel Kimball, Springfield, Mass., on September 25–27, for an absorbing program of technical sessions, excursions and social events. This was the first regional meeting of The American Society of Mechanical Engineers and it was held under the auspices of the Engineering Society of Western Massachusetts and with the coöperation of the Associated Technical Societies of Boston and the A.S.M.E. Local Sections of New England and Eastern New York.

The program for the first day of the meeting was made up of sessions on power in the morning and paper in the afternoon, which were followed by a visit to the Woronoco plant of the Strathmore Paper Company. Here dinner was served and an address delivered by B. A. Franklin, vice-president of the Strathmore Paper Company, on the subject of management. Those not interested in paper were given an opportunity to visit the plant of the Fisk Rubber Company at Chicopee Falls. Dinner was also served and a talk on Rubber and Tire Manufacture was given by William Jameson.

The two simultaneous sessions on tools and textiles held the second morning of the meeting were followed by a luncheon at which the members of the Council of The American Society of Mechanical Engineers were the guests of honor. Mr. Charles L. Newcomb, chairman of the Regional Meeting Committee, presided, and informal addresses on subjects of interest to local engineers were made by Dean Dexter S. Kimball, President A.S.M.E.; J. L. Harrington, President-elect A.S.M.E.; Dr. H. C. Emerson, President Engineering Society of Western Massachusetts; Fred J. Miller, Acting Secretary A.S.M.E., and R. E. Rindfusz, Secretary of the American Writing Paper Company.

Following the luncheon, two automobile parties started, one for the industrial plants of Holyoke and the second to visit the college campuses near Holyoke. Both parties joined at Mt. Tom in time to view the marvelous panorama before sunset. In the meantime, Dean Kimball had gone to the wireless broadcasting station at East Springfield and after the guests were seated at dinner on the mountain they were greeted by a radio message from him.

Dean Kimball's Wireless Message

"I am always rejoiced when I see engineers gathered together for purely social purposes, because then one of the most important functions of the Society is being discharged. We constantly hear the question asked, 'What do I get out of the Society?' That is a fair question and merits a thoughtful reply.

"Engineering societies are somewhat like universities. They offer opportunities in certain directions, and only those who take advantage of these opportunities receive any benefit therefrom. Not the least of these opportunities is the privilege of mingling with fellow-workers in one's chosen field, and with others in allied fields of endeavor. Such intercourse is highly valuable in that it affords an opportunity to evaluate one's own ability and weakness by comparison with others, and such intercourse cannot fail to be mutually helpful in stimulating mental and personal growth.

"An active interest in a great professional society is also very helpful in evaluating the relative importance of the several callings and professions, and in these days of differentiated effort and refined specilization, such clearness of vision becomes increasingly important. Within every such society there are groups that honestly feel that they are the most essential cog in the machinery, and in a larger way this is true of the great congress of trades and callings that constitute industry. Anything that helps in evaluating these many activities is indeed valuable.

"And lastly, in these troubled times when the nations of the earth are seeking new philosophies of life, it is incumbent upon all men to consider carefully what influence their particular calling has had upon this complex thing we call civilization, and what influence this calling may exert in unraveling the tangled problems in which we now find ourselves involved. This applies with peculiar force to the engineer, for this present civilization is largely the work of his mind and hand and the civilization of the future will be largely what he wills it to be.

"In the congresses of engineers only is it possible to gather a concrete idea of what is moving in the minds of those engineers who outline progress and set the pace. The engineer who absents himself from membership in such societies or who, while a member, absents himself from the councils and social gatherings of his fellow-craftsmen, divorces himself from his greatest opportunity for growth and from his greatest opportunity to serve humanity."

The after-dinner program was most happily conducted by H. H. Bowman, President of the Springfield National Bank who was introduced by Dr. H. C. Emerson. The speakers were Mr. Charles L. Newcomb, Chairman of the Springfield Regional Meeting Committee, J. L. Harrington, President-elect of the A.S.M.E., Fred J. Miller, Acting Secretary of the A.S.M.E., and George E. Williamson, President of the Technical Association of the Paper and Pulp Industry. Music was rendered by the Deane Singing Club of Holyoke.

During the evening the members of the A.S.M.E. in Western Massachusetts were advised that their petition for the formation of a Local Section had been granted. An organization meeting was held and the following members were elected to serve on the Executive Committee until the end of the Society year: Chairman Charles L. Newcomb, Holyoke; Vice-Chairman George E. Williamson, Springfield; A. L. Bausman, Springfield; F. O. Wells, Greenfield; A. H. Blaisdell, Pittsfield. Robert W. Mitchell, Secretary and Treasurer of the Engineering Society of Western Massachusetts will also act as secretary of this new Section.

Appreciative mention should be made of the committees who planned the events, who offered a whole-hearted welcome to the guests and who conducted the ceremonies in a most effective manner. The Executive Committee was composed of Chas. L. Newcomb, Chairman, Geo. E. Williamson, Vice-Chairman; Dr. H. C. Emerson, J. Playdon, Jr., Secretary, Wm. G. Starkweather, W. B. Lewis, H. W. Dunbar, M. C. Nelson, Prof. S. W. Dudley, Stillman Shaw, H. E. Harris, C. K. Decherd, C. M. Flagg, B. S. Lewis, S. S. Roby, R. O. Ackerman, and J. J. Crain. The chairmen of the other committees were: Program and Meetings, A. S. Hall; Entertainment, Dr. H. C. Emerson; Publicity, Dr. R. E. Rindfusz; Reception, C. C. Chesney; Finance, John C. Robinson: Registration, Arrangements, Information, A. L. Bausman; Transportation, A. L. Trudo, and Invitations, G. E. Williamson.

Session on Power

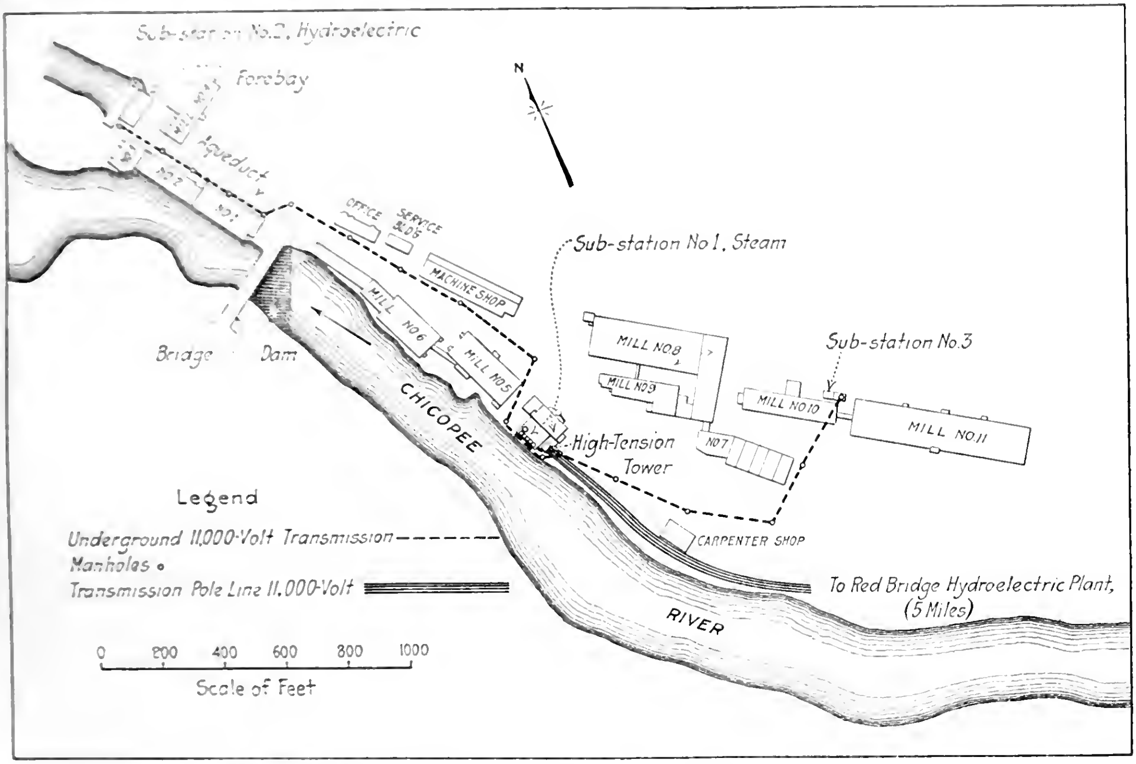
The opening event of the meeting was the Session on Power, which was called to order on Monday, September 25 at 10.00 a.m. in the Hotel Kimball. Mr. Charles L. Newcomb, Chairman of the Regional Meeting Committee greeted the guests, introduced the various officers and committee chairmen and then retired in favor of the presiding chairman for the session, Mr. C. C. Chesney, Manager and Chief Engineer of the Pittsfield Works of the General Electric Company.

The first speaker was Mr. R. A. Packard, Superintendent of Power and Shops of the Ludlow Manufacturing Association, whose paper was entitled Multiple Source of Power for Reliable Large Industrial Plant Operation. Mr. Packard emphasized the importance of continuity in industrial power-plant operation and in closing stressed the need for correct design of multiple source of power, proper installation, and efficient maintenance and operation. Mr. Packard's paper describes the power installation at Ludlow, designed especially for continuity of operation. It is given below, slightly abridged.

Multiple Source Power for the Ludlow Manufacturing Associates

In the generating, transmission and distribution of power for the Ludlow Manufacturing Associates in Ludlow, Mass., natural conditions have contributed largely to a satisfactory arrangement. The sustained flow of the Chicopee River at Red Bridge, 5 miles above the plant, affords a 50-ft. fall for several thousand kilowatts over a majority of the months of the year. Similarly, a modern hydro development at Ludlow in the mill yard delivers power under a 40-ft. head from the same water passed at Red Bridge. The steam power station, also located in the mill yard, acts as standby equipment, the building affording room for a central connecting point of the 11,000-volt transmission lines from the two hydroelectric plants. This latter building also serves as a substation for 550-volt distribution to the nearby mills. A substation in the mill yard hydro-plant also distributes 550-volt power service. From the steam power plant there is an underground 11,000-volt connection to the substation No. 3, where transformation to 550-volts supplies power to the largest group of mills. In this substation is a frequency-changer set, to reduce the Turners Falls Power Company's power from 60 to 40 cycles.

The Red Bridge plant has a water-storage reservoir of 185 acres, while the plant in Ludlow has but 62 acres. With these plants 5 miles apart, it is possible by manipulation of the water to keep the smaller lower reservoir from dropping too low under heavy power demand. The usual arrangement is to pull heavily on this plant when the mills start in the morning, to save water from wasting over the flashboards. At about 10 o'clock the water which passed Red Bridge at 7.30 commences to reinforce the reservoir at Ludlow. When the river flow runs low, the load at the Ludlow hydro-plant must necessarily be cut down until sufficient supply of water has reached it from Red Bridge. On such days, during the last two hours of the afternoon, the load on the former plant is increased to draw the water as low as possible so as to allow a single all-night service unit in operation at Red Bridge to fill up the restricted Ludlow reservoir.



Map Showing Multiple Sources of Power for Ludlow Manufacturing Associates

Of far more significance is the continuity of power service which this system upholds. An interruption of power in all the mills practically never happens. Whenever it does, it is more of a surge of frequency and voltage than anything else, due to a disturbance on some leg of the system. An accident at one plant may automatically dump its load to the remaining sources of power. Interruption of power service on a particular mill group never lasts more than two minutes, so flexible is the system for handling the situation. The correct design and proper control and overload protection have been installed along with correct designs for transmission and distribution. A dead short-circuit across one of the transmission lines, a breaking down of the insulation in the field coils of the 40-cycle end of the frequency-changer set, or lightning surge in the transmission line have given a minimum of trouble. Take, for example, the most severe test which any transmission system has been called upon to stand during the last few years—that of the hail and ice storm of Dec. 5, 1921. This storm carried both transmission lines down, due to high trees laden with ice which dropped across the wires. It was thought the "cut-back" along the line had been sufficient to include these particular trees, but the severity of the storm wrought havoc in a most uncanny manner. The three remaining sources of power at Ludlow were compelled to bear the burden of the load, allowing the mills to proceed with the usual program of production without much interference. The heating system in the mills was shut off and turned into the steam turbine. The temperature outside was not so cold that the heat given off from the process steam and electric power was not sufficient to maintain the rooms at a temperature reasonable under the unusual temporary conditions.

There are factories or mills which do not have the above described unique possibilities of feeder and station arrangement. In such properties, full significance should be given to the proper design and installation of a power system allowing ample transmission capacity for the expansion of the plant. It is much better to have provision for more than one main feeder, so that without disturbing cables already installed, additional capacity can be

placed in multiple with them. Care should be given to secure sufficient carrying capacity to allow uninterrupted service should a cable burn out. A proper installation should consist of well-made joints and firmly secured conduits or cables. One weak link in the system may affect the efficiency of the whole. Many large industrial plants have their own centrally located steam power stations. From the point of view of economy of distribution of steam and power, the proposition is good; the unique and clever designs of stations and the almost perfect development of machinery and apparatus have gone a long way toward securing reliability of operation, but it cannot quite equal a multiple source of power where failure of one automatically, or nearly automatically, calls on the other to support the load.

Some time ago, the Ludlow mills were served with an isolated boiler plant near the Ludlow hydroelectric plant, a left-over of the old-time, slow-speed Corliss Engine days. It had served its usefulness and was torn out. Concentration of steam generation can be most efficiently handled at the main steam plant. This illustrates conditions which have existed in other growing plants, the tendency in having too many sources of power both for steam and electricity, which when reduced in number and remodeled, have conduced to greater reliability and economy.

Once an ideal system of generation and transmission from a multiple source is in operation, its personnel of operation, inspection and maintenance is of great importance. A definite periodical examination of generating, transforming and distributing equipment is of prime importance. The cleaning and inspection of compensators will save heavy dividends. A large number of motors necessarily must be started and stopped by ordinary mill hands. No one should be allowed to handle such apparatus without first having been carefully instructed and without passing an examination satisfactory to the electrical maintenance foreman.

R. J. S. Pigott, works manager of the Crosby Steam Gauge and Valve Company, Boston, Mass., followed Mr. Packard with an address on Economies in the Use of Fuel. In his opening remarks, Mr. Pigott discussed the question of central-station power for the isolated plant and emphasized the difficulty of even stating fundamental principles that, without qualifications, would guide in the choice between the isolated plant and central-station service. He stressed the need for considering each problem on its individual merits and deciding on the basis of cheaper power costs. He also pointed out the necessity for the economical layout of piping systems, the use of stokers even in one-man plants, the operation of hammers by compressed air, the centralizing of air compressors and the intelligent installation and use of recording and indicating instruments if a proper economical operation is to be attained in the industrial plant.

The discussion at this session centered on the relative reliability and economy of the private plant as compared with the central station. This led to a consideration of the use of steam-metering devices, and R. E. Woolley, of the Schenectady Works, General Electric Company, told of the careful records that are kept by the 160 steam-flow meters in the shops of that company. The steam used in each shop is metered, totaled, and subtracted from the total steam produced. The remainder represents the losses, which are scrutinized carefully. Any variations in this figure lead to investigations and inspections.

Session on Paper

Mr. George E. Williamson, chief engineer of the Strathmore Paper Company, and president of the Technical Association of the Paper and Pulp Industry, presided at the session on Paper which was held Monday afternoon, September 25, in the Hotel Kimball. Two papers were presented—one on Applying Engineering Principles to the Selection of Paper, by Dr. R. E. Rindfusz, secretary of the American Writing Paper Company, and one on Steam Utilization in a Modern Newsprint Mill, by S. W. Slater and J. E. A. Warner, engineer and assistant engineer, respectively, of the St. Maurice Paper Co., Ltd., of Cape Madeleine, Quebec.

The paper on Steam Utilization in a Modern Newsprint Mill appeared in the September issue of Mechanical Engineering. An abstract of the paper by Dr. Rindfusz follows:

Applying Engineering Principles to the Selection of Paper

In the manufacturing and distributing of paper, as in any other class of industry, the applying of engineering principles or the using of scientific methods means simply the employment of the best available common-sense—collecting the pertinent facts and building a course of action from them, with an open mind that will allow modification when other or weightier facts may be brought to bear. A brief background of conditions in the paper industry is necessary for an understanding of the need of engineering practice in the selection of paper.

While it is beside the point to present a brief for or against the paper industry as compared with other industries, we of the paper business are forced to admit that in large measure, instead of directing our development in a far-sighted and common-sense manner, we have allowed it to drift. The paper industry has been cursed by a multiplicity of brands, both mill and private, though chiefly the latter. This grew up, perhaps, as a natural evolution. A certain brand of paper, for instance, would be found to have wide use. Some mill or paper jobber would desire to cut into this established business. To do this he would create a new brand closely resembling the other, but slightly lower in quality and price. The maker of the first brand might then fall into the temptation also to cheapen. By constant repetition of this process qualities were rendered unstable, and an immense number of confusing and meaningless brands put on the market. The competition became one of price, and the quality of paper applied to any given use tended gradually downward until it became almost the exception rather than the rule to find the right paper employed in any particular use.

The result of all this confusion in paper qualities and shortsightedness in sales policy has been the fostering of chaotic manufacturing conditions, complex distribution problems, and ineffective service to the needs of the consumer. It is evident, therefore, that engineering principles are needed for remedying this condition.

The chief users of paper have finally become awakened to the inefficient methods of manufacturing and distribution which they have been forced to support, and to the absurdities into which they have been led in their selection of papers. They have, very naturally, therefore, in many cases set up specific specifications based on paper testing. This is open to serious objection because paper-testing methods are not fully developed, and the translation of use requirements into terms of paper tests, and of the paper tests into terms of manufacturing skill, is indeed a difficult and roundabout procedure. The better procedure is for the manufacturer to make his papers each for a specific use, and after he has found a given paper thoroughly satisfactory for its particular use, then to establish his test specifications and employ them for the maintenance of quality. If a complete enough set of test specifications can be developed, they can then be transferred from the manufacturer to the purchaser, who can use them for judging the offerings of various makers.

To an engineer, it is at once obvious that the fixing of each different member of a line of products for a specific use can be possible only where a complete standardization has been brought about. In the paper industry seven phases of this standardization have been established. These are the standardization of:

1 Raw materials
2 Process
3 Product
4 Line (grade standardization)
5 Distribution
6 Price
7 Use.

It is only when the others have been brought about that the seventh phase, which we are now discussing, can become effectively applied.

The method employed in translating each individual requirement of a user into terms of the proper paper is really quite simple. We find that all of these requirements may be grouped under four main factors, namely:

1 Longevity, or the length of time for which the paper must resist deterioration
2 Treatment, or the amount of separating, of handling, fold-

ing, binding, or exposure to which the paper will be subjected

3 Impress, or the mechanical method of applying reading matter, illustrations, decorations, or rulings

4 Appearance, or the character or sense appeal of the paper itself.

The longevity of a sheet depends upon its chemical constituents. If it contains mechanical wood pulp, ground wood, such as we find in newsprint, its life will be only transient; if it is made of chemical wood pulp alone, or in preponderance, its life will be temporary; if of mixed cotton fiber and wood pulp in approximately equal proportions, it may be classed as semi-permanent; and if all, or very predominatingly cotton fiber, it is for all practical purposes permanent. The paper made from cotton rags upon which Gutenberg himself printed the Bible is, as is well known, still extant.

Of the four factors given above, the first three may be rated by physical and chemical tests. An analysis will give the key to the longevity of the sheet. The tensile strength, folding endurance, stiffness, bursting strength, etc., will give an indication of its resistance to severe treatment. Tests of its absorbency, surface, stiffness and opacity, as well as the actual application, will show its suitability for impress. Appearance alone is a sense appeal, and hence subject to personal opinion. Nevertheless, if a paper is to be classed as first grade in its appearance, its sense appeal must be so general as to be recognized by at least nine out of ten average and uninitiated observers. If it does not do this, it would in most cases be a waste of money to buy high-grade paper for the sake of its appearance since genuine paper experts are comparatively rare. The appeal of various finishes, such as the linen finish, or lawn finish, may usually be considered quite general within certain groups of users.

Management in the Paper Industry

Following the visit to the Woronoco plant to the Strathmore Paper Company, B. F. Franklin, vice-president of the company, delivered an address dealing with the general principles of management and their applications to the paper industry. Mr. Franklin stated that any adequate system of management to be successful must have ideals, aims, policies and realizations.

The most important ideal is that of service, as industry not only has the important reason for existence that it renders service to buyers, but also is a focusing device for increasing the service value of individuals engaged in industry. A second ideal is that underlying the desire to make people happy.

The speaker stated the four aims of management to be: profit for the perpetuation and expansion of the industry for service; the payment of fair wages; the manufacture of the best product for a particular use; and the marketing of this product with a fair profit.

The guiding policies of management must be, according to Mr. Franklin: proper selection and training of personnel; reward to employees in proportion to service rendered; maintenance of plant in up-to-minute condition of repair and improvement; and the constant knowledge of details of the business.

Some definite realizations must come from proper ideals, aims, and policies and the speaker treated them somewhat in detail. It must be realized, first, that success in industry is derived primarily from men and not from machinery. Furthermore, after a knowledge of the materials to be used in the industry, there must be a service of well-defined methods which he divided into administrative and technical. Administrative methods must be provided for costs, records of part performances, expense analysis and control, production planning, bonus payment, quality control, and for the human element which has not been properly treated to get the best results. In discussing technical methods, Mr. Franklin pointed out that the paper industry differed from all others in the intricacy of and variations in its processes. He spoke, however, very optimistically of the coöperation progress that had been made in the industry in standardization and development.

Session on Preservation of Wood Roofs

The textile men attending the meeting were very much interested in the paper by Wendell S. Brown, of F. P. Sheldon & Son, Providence, R. I., entitled The Preservation of Decaying Wood Roofs, which appears on page 709 of this issue of Mechanical Engineering. The paper has an important bearing on the roofs of buildings which house processes requiring moisture in the air. The discussion brought out under the chairmanship of Dr. H. C. Emerson, president of the Engineering Society of Western Massachusetts, will appear in the December issue of Mechanical Engineering.

Session on Standardization of Tools

Dr. E. C. Gilbert, works manager of the Chapman Valve Company, presided at the session held Tuesday morning, September 26, when two papers dealing with the standardization of tools were presented. The first paper, by Carl J. Oxford, chief engineer of the National Twist Drill and Tool Company, Detroit, Mich., dealt with the Standardization of Small Tools, and the second, by Fred H. Colvin and K. H. Condit, editors of the *American Machinist*, offered suggestions as to the Standardization of Machine Tools. These two papers appear in this issue of Mechanical Engineering.

On the subject of small tools, W. A. Viall, secretary of the Brown and Sharpe Mfg. Co., of Providence, R. I., in a written discussion agreed fully with Mr. Oxford in the statement that manufacturers' lists of small tools can be greatly reduced. Mr. Viall expressed surprise at the great demand for special tools which may vary but slightly from tools of standard dimensions, and he gave twenty-one items from a day's orders for cutters which varied by only small amounts in diameter, arbor size, and thickness from the stock article. His discussion closed with an especially strong plea for careful study by tool users of the lists of standard tools produced by tool manufacturers and the formulation of design, that will permit the use of standard small tools.

F. O. Wells, of Greenfield, Mass., emphasized the importance of small-tool standardization. He felt, however, that manufacturers and users must come together to determine real needs and to agree upon possible elimination in lists of manufactured small tools.

Arthur F. Murray, of the Westinghouse Electric and Manufacturing Co., Springfield, treated the subject from the standpoint of the user of small tools. He found that even with the large list of tools available for the manufacturer it was necessary for him to design special tools. Mr. Murray stated that designing engineers should be more familiar with methods for utilizing standard tools by reworking them for special use.

Elmer H. Neff, of the Brown and Sharpe Manufacturing Co., New York, stated as his opinion that the buyer must dictate as to the tools he requires. He disagreed with the idea that manufacturers could, without coöperation with the user, eliminate any of the list of tools to be supplied by a manufacturer of small tools.

Selby Haar, electrical and mechanical engineer, New York, agreed with the idea of treating special tools as modifications of standard tools.

Frank B. Gilbreth, consulting engineer, Montclair, N. J., spoke from the standpoint of one who has occasion to study the manner in which various manufacturers store their tools. Generally he found that there was a lack of a clear idea of the proper uses of the various tools, and that each user wanted something different. The standardization not only of small tools and machine tools but of every kind of a tool would produce tremendous savings in production costs.

In the discussion on Standardization of Machine Tools, Luther D. Burlingame, of the Brown and Sharpe Manufacturing Co., Providence, submitted a written discussion in which he endorsed heartily the manner in which Messrs. Colvin and Condit treated the principles of machine-tool standardization. He emphasized the principle that standardization is often a matter of elimination and also that it is useless to adopt theoretical standards which manufacturers and users will ignore. Where these two principles are followed, standardization does not hamper progress.

Mr. Burlingame recommended the adherence to the Morse and Brown and Sharpe tapers. In adopting standards for shafting keys he suggested that flat keys be eliminated for small sizes and square keys for large sizes. In the matter of screw threads Mr. Burlingame advocated the adoption of such threads as could be agreed upon by both Great Britain and America on a common standard based on the inch.

Governor Hartness Emphasizes Evils of Industrial Strife

Chief Executive of Vermont Discusses Problems of a Machine-made Civilization at Machine Tool Exhibition at New Haven, September 21-23—Messrs. Buckingham and Wikander Stress Standardization Principles—12,000 Appreciative Visitors See 135 Novel Machine Exhibits

BESIDES furnishing an array of interesting and novel exhibits of machine tools and machine-shop devices to over 12,000 visitors the New Haven Machine Tool Exhibition held September 21-23 in the Mason Laboratory provided a platform for a number of instructive addresses. Governor James Hartness, of Vermont, Past-President of the A.S.M.E., spoke very forcibly of the far-reaching influence of machine tools on present-day civilization and pointed out the need for constructive thought about future problems. The importance of standardization was stressed by Oscar R. Wikander, consulting engineer of New York, who told of the progress of German standardization and by Earl Buckingham, of the Pratt & Whitney Co., Hartford, Conn., who outlined fundamental standardization principles for precision production. Another interesting talk was given by Oswald W. Knauth, Secretary of the National Bureau of Economical Research, who presented some facts about individual incomes in the United States. Governor Hartness' remarks appear in full below as do liberal abstracts of the talks by Messrs. Knauth, Wikander and Buckingham. Other speakers were Henry B. Sargent, President of the New Haven Chamber of Commerce, who extended the greetings of the city to the exhibitors and visitors, Dean Charles Warren, Sheffield Scientific School, who spoke on Coöperation between Colleges and Industry and M. S. Liming, Manager of the Boston Chamber of Commerce who told of the Outlook for Industry in New England. In addition, William Calkins of Detroit described the design, manufacture and performance of twist drills and Gardner T. Swarts, Jr., of Providence, R. I., demonstrated an application of Graphic Control to Machine Tool Manufacture. A number of motion pictures were shown.

The 135 exhibits elicited so much favorable comment that the exhibition is being seriously considered as a permanent annual affair. The coöperation of the authorities of Sheffield Scientific School who permitted the use of Mason Laboratory and of the New Haven Chamber of Commerce who assisted whole heartedly in the arrangements should receive special mention. The success of the exhibition is due to the efforts of the Exhibition Committee and the Executive Committee of the New Haven Branch Connecticut Section of The American Society of Mechanical Engineers which assumed major responsibility. The names of the men who made up these committees are K. F. Lees, Chairman Executive Committee, H. R. Westcott, Chairman Exhibition Committee, A. C. Jewett, N. E. Horn, A. L. Breitenstein, G. A. Stetson, F. W. Shatts, S. W. Dudley, H. L. Seward, W. L. Bean, H. Gfroerer, Wm. Buxbaum.

INFLUENCE OF THE MACHINE TOOL IN AMERICA

By JAMES HARTNESS,[1] GOVERNOR OF VERMONT

THE machine tool has been a wonderful instrument in extending the efforts of man, in amplifying the product that he could turn out. The machine tool, as all know, is the father of machinery, and as such it is largely responsible for the serious condition that confronts us today.

One hundred years ago, or even fifty years ago, the world was a very different place from the world we have today. Then work was done more by hand, and nearly all families were more or less self-supporting in producing the things that they needed. Their own food they would grow, and make their own shoes, perhaps, and so on through the whole range of the necessities. Men worked hard to produce the bare necessities of life.

With the introduction and development of the machine tool and its product, machinery, man's efforts now produce in many instances a thousand times the value that was produced before he was aided by this machinery.

At the present time we are facing the result of the strikes in the coal mines and on the transportation systems, and we are learning, none too early, that our whole scheme of management of our industrial affairs, our financial affairs, and our business affairs, fails to keep pace with the development of the world as it has grown under the work of the machine tool and its products.
